
pandas: powerful Python data analysis toolkit

Release 1.0.1

Wes McKinney and the Pandas Development Team

Mar 09, 2020

CONTENTS

1	What's new in 1.0.1 (February 5, 2020)	3
1.1	Fixed regressions	3
1.2	Deprecations	4
1.3	Bug fixes	4
1.4	Contributors	4
2	Getting started	5
2.1	Installation	5
2.1.1	Python version support	5
2.1.2	Installing pandas	5
2.1.3	Running the test suite	7
2.1.4	Dependencies	8
2.2	Package overview	10
2.2.1	Data structures	11
2.2.2	Mutability and copying of data	11
2.2.3	Getting support	11
2.2.4	Community	12
2.2.5	Project governance	12
2.2.6	Development team	12
2.2.7	Institutional partners	12
2.2.8	License	12
2.3	10 minutes to pandas	13
2.3.1	Object creation	13
2.3.2	Viewing data	15
2.3.3	Selection	17
2.3.4	Missing data	21
2.3.5	Operations	22
2.3.6	Merge	25
2.3.7	Grouping	27
2.3.8	Reshaping	28
2.3.9	Time series	30
2.3.10	Categoricals	32
2.3.11	Plotting	33
2.3.12	Getting data in/out	35
2.3.13	Gotchas	37
2.4	Essential basic functionality	37
2.4.1	Head and tail	37
2.4.2	Attributes and underlying data	38
2.4.3	Accelerated operations	40
2.4.4	Flexible binary operations	40

2.4.5	Descriptive statistics	49
2.4.6	Function application	57
2.4.7	Reindexing and altering labels	69
2.4.8	Iteration	79
2.4.9	.dt accessor	82
2.4.10	Vectorized string methods	85
2.4.11	Sorting	86
2.4.12	Copying	91
2.4.13	dtypes	92
2.4.14	Selecting columns based on <code>dtype</code>	102
2.5	Intro to data structures	105
2.5.1	Series	105
2.5.2	DataFrame	111
2.6	Comparison with other tools	127
2.6.1	Comparison with R / R libraries	127
2.6.2	Comparison with SQL	140
2.6.3	Comparison with SAS	151
2.6.4	Comparison with Stata	166
2.7	Tutorials	179
2.7.1	Internal guides	180
2.7.2	Community guides	180
3	User Guide	183
3.1	IO tools (text, CSV, HDF5, ...)	183
3.1.1	CSV & text files	184
3.1.2	JSON	219
3.1.3	HTML	233
3.1.4	Excel files	242
3.1.5	OpenDocument Spreadsheets	248
3.1.6	Binary Excel (.xlsb) files	249
3.1.7	Clipboard	249
3.1.8	Pickling	250
3.1.9	msgpack	253
3.1.10	HDF5 (PyTables)	253
3.1.11	Feather	280
3.1.12	Parquet	282
3.1.13	ORC	285
3.1.14	SQL queries	285
3.1.15	Google BigQuery	292
3.1.16	Stata format	292
3.1.17	SAS formats	295
3.1.18	SPSS formats	295
3.1.19	Other file formats	296
3.1.20	Performance considerations	296
3.2	Indexing and selecting data	299
3.2.1	Different choices for indexing	300
3.2.2	Basics	300
3.2.3	Attribute access	303
3.2.4	Slicing ranges	305
3.2.5	Selection by label	306
3.2.6	Selection by position	310
3.2.7	Selection by callable	313
3.2.8	IX indexer is deprecated	315
3.2.9	Indexing with list with missing labels is deprecated	316

3.2.10	Selecting random samples	318
3.2.11	Setting with enlargement	320
3.2.12	Fast scalar value getting and setting	321
3.2.13	Boolean indexing	322
3.2.14	Indexing with <code>isin</code>	324
3.2.15	The <code>where()</code> Method and Masking	326
3.2.16	The <code>query()</code> Method	330
3.2.17	Duplicate data	341
3.2.18	Dictionary-like <code>get()</code> method	343
3.2.19	The <code>lookup()</code> method	344
3.2.20	Index objects	344
3.2.21	Set / reset index	347
3.2.22	Returning a view versus a copy	350
3.3	MultiIndex / advanced indexing	353
3.3.1	Hierarchical indexing (MultiIndex)	353
3.3.2	Advanced indexing with hierarchical index	359
3.3.3	Sorting a MultiIndex	371
3.3.4	Take methods	374
3.3.5	Index types	376
3.3.6	Miscellaneous indexing FAQ	386
3.4	Merge, join, and concatenate	390
3.4.1	Concatenating objects	390
3.4.2	Database-style DataFrame or named Series joining/merging	402
3.4.3	Timeseries friendly merging	420
3.5	Reshaping and pivot tables	423
3.5.1	Reshaping by pivoting DataFrame objects	423
3.5.2	Reshaping by stacking and unstacking	425
3.5.3	Reshaping by Melt	433
3.5.4	Combining with stats and GroupBy	434
3.5.5	Pivot tables	435
3.5.6	Cross tabulations	439
3.5.7	Tiling	441
3.5.8	Computing indicator / dummy variables	442
3.5.9	Factorizing values	445
3.5.10	Examples	446
3.5.11	Exploding a list-like column	449
3.6	Working with text data	450
3.6.1	Text Data Types	450
3.6.2	String Methods	453
3.6.3	Splitting and replacing strings	455
3.6.4	Concatenation	459
3.6.5	Indexing with <code>.str</code>	464
3.6.6	Extracting substrings	465
3.6.7	Testing for Strings that match or contain a pattern	469
3.6.8	Creating indicator variables	470
3.6.9	Method summary	470
3.7	Working with missing data	471
3.7.1	Values considered “missing”	472
3.7.2	Inserting missing data	475
3.7.3	Calculations with missing data	475
3.7.4	Sum/prod of empties/nans	477
3.7.5	NA values in GroupBy	477
3.7.6	Filling missing values: <code>fillna</code>	478
3.7.7	Filling with a PandasObject	479

3.7.8	Dropping axis labels with missing data: dropna	481
3.7.9	Interpolation	481
3.7.10	Replacing generic values	490
3.7.11	String/regular expression replacement	491
3.7.12	Numeric replacement	494
3.7.13	Experimental NA scalar to denote missing values	497
3.8	Categorical data	501
3.8.1	Object creation	501
3.8.2	CategoricalDtype	507
3.8.3	Description	508
3.8.4	Working with categories	508
3.8.5	Sorting and order	512
3.8.6	Comparisons	515
3.8.7	Operations	518
3.8.8	Data munging	519
3.8.9	Getting data in/out	527
3.8.10	Missing data	528
3.8.11	Differences to R's <i>factor</i>	529
3.8.12	Gotchas	529
3.9	Nullable integer data type	533
3.9.1	Construction	533
3.9.2	Operations	535
3.9.3	Scalar NA Value	536
3.10	Nullable Boolean Data Type	537
3.10.1	Indexing with NA values	537
3.10.2	Kleene Logical Operations	537
3.11	Visualization	539
3.11.1	Basic plotting: <code>plot</code>	539
3.11.2	Other plots	542
3.11.3	Plotting with missing data	573
3.11.4	Plotting Tools	574
3.11.5	Plot Formatting	582
3.11.6	Plotting directly with <code>matplotlib</code>	606
3.12	Computational tools	607
3.12.1	Statistical functions	607
3.12.2	Window Functions	612
3.12.3	Aggregation	627
3.12.4	Expanding windows	631
3.12.5	Exponentially weighted windows	634
3.13	Group By: split-apply-combine	637
3.13.1	Splitting an object into groups	638
3.13.2	Iterating through groups	645
3.13.3	Selecting a group	646
3.13.4	Aggregation	647
3.13.5	Transformation	653
3.13.6	Filtration	660
3.13.7	Dispatching to instance methods	661
3.13.8	Flexible <code>apply</code>	663
3.13.9	Other useful features	665
3.13.10	Examples	675
3.14	Time series / date functionality	677
3.14.1	Overview	679
3.14.2	Timestamps vs. Time Spans	681
3.14.3	Converting to timestamps	682

3.14.4	Generating ranges of timestamps	686
3.14.5	Timestamp limitations	689
3.14.6	Indexing	689
3.14.7	Time/date components	697
3.14.8	DateOffset objects	698
3.14.9	Time Series-Related Instance Methods	713
3.14.10	Resampling	715
3.14.11	Time span representation	722
3.14.12	Converting between representations	730
3.14.13	Representing out-of-bounds spans	731
3.14.14	Time zone handling	732
3.15	Time deltas	739
3.15.1	Parsing	739
3.15.2	Operations	741
3.15.3	Reductions	745
3.15.4	Frequency conversion	746
3.15.5	Attributes	748
3.15.6	TimedeltaIndex	749
3.15.7	Resampling	754
3.16	Styling	754
3.16.1	Building styles	754
3.16.2	Finer control: slicing	757
3.16.3	Finer Control: Display Values	758
3.16.4	Builtin styles	758
3.16.5	Sharing styles	760
3.16.6	Other Options	761
3.16.7	Fun stuff	764
3.16.8	Export to Excel	765
3.16.9	Extensibility	766
3.17	Options and settings	767
3.17.1	Overview	767
3.17.2	Getting and setting options	768
3.17.3	Setting startup options in Python/IPython environment	769
3.17.4	Frequently Used Options	769
3.17.5	Available options	776
3.17.6	Number formatting	777
3.17.7	Unicode formatting	778
3.17.8	Table schema display	779
3.18	Enhancing performance	779
3.18.1	Cython (writing C extensions for pandas)	780
3.18.2	Using Numba	785
3.18.3	Expression evaluation via eval()	787
3.19	Scaling to large datasets	795
3.19.1	Load less data	796
3.19.2	Use efficient datatypes	797
3.19.3	Use chunking	799
3.19.4	Use other libraries	800
3.20	Sparse data structures	805
3.20.1	SparseArray	806
3.20.2	SparseDtype	806
3.20.3	Sparse accessor	807
3.20.4	Sparse calculation	807
3.20.5	Migrating	808
3.20.6	Interaction with scipy.sparse	810

3.21	Frequently Asked Questions (FAQ)	813
3.21.1	DataFrame memory usage	813
3.21.2	Using if/truth statements with pandas	815
3.21.3	NaN, Integer NA values and NA type promotions	817
3.21.4	Differences with NumPy	819
3.21.5	Thread-safety	820
3.21.6	Byte-Ordering issues	820
3.22	Cookbook	820
3.22.1	Idioms	820
3.22.2	Selection	825
3.22.3	MultiIndexing	828
3.22.4	Missing data	832
3.22.5	Grouping	833
3.22.6	Timeseries	843
3.22.7	Merge	844
3.22.8	Plotting	845
3.22.9	Data In/Out	846
3.22.10	Computation	851
3.22.11	Timedeltas	852
3.22.12	Aliasing axis names	854
3.22.13	Creating example data	855
4	API reference	857
4.1	Input/output	857
4.1.1	Pickling	857
4.1.2	Flat file	859
4.1.3	Clipboard	869
4.1.4	Excel	869
4.1.5	JSON	875
4.1.6	HTML	882
4.1.7	HDFStore: PyTables (HDF5)	884
4.1.8	Feather	888
4.1.9	Parquet	889
4.1.10	ORC	889
4.1.11	SAS	890
4.1.12	SPSS	891
4.1.13	SQL	891
4.1.14	Google BigQuery	894
4.1.15	STATA	896
4.2	General functions	898
4.2.1	Data manipulations	898
4.2.2	Top-level missing data	929
4.2.3	Top-level conversions	934
4.2.4	Top-level dealing with datetimelike	936
4.2.5	Top-level dealing with intervals	945
4.2.6	Top-level evaluation	947
4.2.7	Hashing	949
4.2.8	Testing	950
4.3	Series	950
4.3.1	Constructor	950
4.3.2	Attributes	1173
4.3.3	Conversion	1174
4.3.4	Indexing, iteration	1175
4.3.5	Binary operator functions	1176

4.3.6	Function application, groupby & window	1177
4.3.7	Computations / descriptive stats	1177
4.3.8	Reindexing / selection / label manipulation	1178
4.3.9	Missing data handling	1179
4.3.10	Reshaping, sorting	1179
4.3.11	Combining / joining / merging	1180
4.3.12	Time series-related	1180
4.3.13	Accessors	1180
4.3.14	Plotting	1280
4.3.15	Serialization / IO / conversion	1321
4.4	DataFrame	1321
4.4.1	Constructor	1321
4.4.2	Attributes and underlying data	1639
4.4.3	Conversion	1640
4.4.4	Indexing, iteration	1640
4.4.5	Binary operator functions	1641
4.4.6	Function application, GroupBy & window	1642
4.4.7	Computations / descriptive stats	1642
4.4.8	Reindexing / selection / label manipulation	1643
4.4.9	Missing data handling	1644
4.4.10	Reshaping, sorting, transposing	1644
4.4.11	Combining / joining / merging	1645
4.4.12	Time series-related	1645
4.4.13	Metadata	1646
4.4.14	Plotting	1646
4.4.15	Sparse accessor	1692
4.4.16	Serialization / IO / conversion	1693
4.5	Pandas arrays	1694
4.5.1	pandas.array	1695
4.5.2	Datetime data	1698
4.5.3	Timedelta data	1718
4.5.4	Timespan data	1727
4.5.5	Period	1727
4.5.6	Interval data	1742
4.5.7	Nullable integer	1756
4.5.8	Categorical data	1761
4.5.9	Sparse data	1766
4.5.10	Text data	1768
4.5.11	Boolean data with missing values	1770
4.6	Panel	1772
4.7	Index objects	1772
4.7.1	Index	1772
4.7.2	Numeric Index	1828
4.7.3	CategoricalIndex	1832
4.7.4	IntervalIndex	1841
4.7.5	MultiIndex	1853
4.7.6	DatetimeIndex	1870
4.7.7	TimedeltaIndex	1897
4.7.8	PeriodIndex	1905
4.8	Date offsets	1912
4.8.1	DateOffset	1912
4.8.2	BusinessDay	1917
4.8.3	BusinessHour	1920
4.8.4	CustomBusinessDay	1924

4.8.5	CustomBusinessHour	1928
4.8.6	MonthOffset	1932
4.8.7	MonthEnd	1935
4.8.8	MonthBegin	1938
4.8.9	BusinessMonthEnd	1941
4.8.10	BusinessMonthBegin	1944
4.8.11	CustomBusinessMonthEnd	1947
4.8.12	CustomBusinessMonthBegin	1951
4.8.13	SemiMonthOffset	1956
4.8.14	SemiMonthEnd	1959
4.8.15	SemiMonthBegin	1962
4.8.16	Week	1965
4.8.17	WeekOfMonth	1968
4.8.18	LastWeekOfMonth	1972
4.8.19	QuarterOffset	1976
4.8.20	BQuarterEnd	1979
4.8.21	BQuarterBegin	1982
4.8.22	QuarterEnd	1986
4.8.23	QuarterBegin	1989
4.8.24	YearOffset	1992
4.8.25	BYearEnd	1995
4.8.26	BYearBegin	1998
4.8.27	YearEnd	2001
4.8.28	YearBegin	2004
4.8.29	FY5253	2007
4.8.30	FY5253Quarter	2011
4.8.31	Easter	2016
4.8.32	Tick	2020
4.8.33	Day	2024
4.8.34	Hour	2028
4.8.35	Minute	2031
4.8.36	Second	2035
4.8.37	Milli	2039
4.8.38	Micro	2042
4.8.39	Nano	2046
4.8.40	BDay	2050
4.8.41	BMonthEnd	2053
4.8.42	BMonthBegin	2055
4.8.43	CBMonthEnd	2058
4.8.44	CBMonthBegin	2062
4.8.45	CDay	2065
4.9	Frequencies	2068
4.9.1	pandas.tseries.frequencies.to_offset	2069
4.10	Window	2069
4.10.1	Standard moving window functions	2070
4.10.2	Standard expanding window functions	2088
4.10.3	Exponentially-weighted moving window functions	2101
4.10.4	Window Indexer	2103
4.11	GroupBy	2104
4.11.1	Indexing, iteration	2104
4.11.2	Function application	2106
4.11.3	Computations / descriptive stats	2108
4.12	Resampling	2150
4.12.1	Indexing, iteration	2150

4.12.2	Function application	2151
4.12.3	Upsampling	2155
4.12.4	Computations / descriptive stats	2167
4.13	Style	2172
4.13.1	Styler constructor	2172
4.13.2	Styler properties	2187
4.13.3	Style application	2187
4.13.4	Builtin styles	2187
4.13.5	Style export and import	2188
4.14	Plotting	2188
4.14.1	pandas.plotting.andrews_curves	2188
4.14.2	pandas.plotting.autocorrelation_plot	2189
4.14.3	pandas.plotting.bootstrap_plot	2189
4.14.4	pandas.plotting.boxplot	2190
4.14.5	pandas.plotting.deregister_matplotlib_converters	2197
4.14.6	pandas.plotting.lag_plot	2197
4.14.7	pandas.plotting.parallel_coordinates	2197
4.14.8	pandas.plotting.plot_params	2198
4.14.9	pandas.plotting.radviz	2198
4.14.10	pandas.plotting.register_matplotlib_converters	2199
4.14.11	pandas.plotting.scatter_matrix	2201
4.14.12	pandas.plotting.table	2201
4.15	General utility functions	2202
4.15.1	Working with options	2202
4.15.2	Testing functions	2216
4.15.3	Exceptions and warnings	2219
4.15.4	Data types related functionality	2222
4.16	Extensions	2249
4.16.1	pandas.api.extensions.register_extension_dtype	2250
4.16.2	pandas.api.extensions.register_dataframe_accessor	2250
4.16.3	pandas.api.extensions.register_series_accessor	2251
4.16.4	pandas.api.extensions.register_index_accessor	2253
4.16.5	pandas.api.extensions.ExtensionDtype	2254
4.16.6	pandas.api.extensions.ExtensionArray	2257
4.16.7	pandas.arrays.PandasArray	2270
4.16.8	pandas.api.indexers.check_array_indexer	2270
5	Development	2273
5.1	Contributing to pandas	2273
5.1.1	Where to start	2274
5.1.2	Bug reports and enhancement requests	2275
5.1.3	Working with the code	2275
5.1.4	Contributing to the documentation	2279
5.1.5	Contributing to the code base	2298
5.1.6	Contributing your changes to <i>pandas</i>	2310
5.2	pandas code style guide	2313
5.2.1	Patterns	2314
5.2.2	String formatting	2314
5.3	Pandas Maintenance	2315
5.3.1	Roles	2316
5.3.2	Tasks	2316
5.3.3	Issue Triage	2316
5.3.4	Closing Issues	2317
5.3.5	Reviewing Pull Requests	2317

5.3.6	Cleaning up old Issues	2318
5.3.7	Cleaning up old Pull Requests	2318
5.3.8	Becoming a pandas maintainer	2318
5.4	Internals	2318
5.4.1	Indexing	2318
5.4.2	Subclassing pandas data structures	2321
5.5	Extending pandas	2321
5.5.1	Registering custom accessors	2321
5.5.2	Extension types	2322
5.5.3	Subclassing pandas data structures	2325
5.5.4	Plotting backends	2328
5.6	Developer	2328

To the development guide

WHAT'S NEW IN 1.0.0 (JANUARY 29, 2020)

These are the changes in pandas 1.0.0. See [release](#) for a full changelog including other versions of pandas.

Note: The pandas 1.0 release removed a lot of functionality that was deprecated in previous releases (see [below](#) for an overview). It is recommended to first upgrade to pandas 0.25 and to ensure your code is working without warnings, before upgrading to pandas 1.0.

1.1 New Deprecation Policy

Starting with Pandas 1.0.0, pandas will adopt a variant of [SemVer](#) to version releases. Briefly,

- Deprecations will be introduced in minor releases (e.g. 1.1.0, 1.2.0, 2.1.0, ...)
- Deprecations will be enforced in major releases (e.g. 1.0.0, 2.0.0, 3.0.0, ...)
- API-breaking changes will be made only in major releases (except for experimental features)

See [Version Policy](#) for more.

`{{ header }}`

1.2 Enhancements

1.2.1 Using Numba in `rolling.apply` and `expanding.apply`

We've added an `engine` keyword to `apply()` and `apply()` that allows the user to execute the routine using [Numba](#) instead of Cython. Using the Numba engine can yield significant performance gains if the `apply` function can operate on numpy arrays and the data set is larger (1 million rows or greater). For more details, see [rolling apply documentation](#) ([GH28987](#), [GH30936](#))

1.2.2 Defining custom windows for rolling operations

We've added a `pandas.api.indexers.BaseIndexer()` class that allows users to define how window bounds are created during rolling operations. Users can define their own `get_window_bounds` method on a `pandas.api.indexers.BaseIndexer()` subclass that will generate the start and end indices used for each window during the rolling aggregation. For more details and example usage, see the [custom window rolling documentation](#)

1.2.3 Converting to Markdown

We've added `to_markdown()` for creating a markdown table (GH11052)

```
In [1]: df = pd.DataFrame({"A": [1, 2, 3], "B": [1, 2, 3]}, index=['a', 'a', 'b'])

In [2]: print(df.to_markdown())
|   | A | B |
| :--- | ---:| ---:|
| a | 1 | 1 |
| a | 2 | 2 |
| b | 3 | 3 |
```

1.3 Experimental new features

1.3.1 Experimental NA scalar to denote missing values

A new `pd.NA` value (singleton) is introduced to represent scalar missing values. Up to now, pandas used several values to represent missing data: `np.nan` is used for this for float data, `np.nan` or `None` for object-dtype data and `pd.NaT` for datetime-like data. The goal of `pd.NA` is to provide a “missing” indicator that can be used consistently across data types. `pd.NA` is currently used by the nullable integer and boolean data types and the new string data type (GH28095).

Warning: Experimental: the behaviour of `pd.NA` can still change without warning.

For example, creating a Series using the nullable integer dtype:

```
In [3]: s = pd.Series([1, 2, None], dtype="Int64")

In [4]: s
Out[4]:
0      1
1      2
2    <NA>
Length: 3, dtype: Int64

In [5]: s[2]
Out[5]: <NA>
```

Compared to `np.nan`, `pd.NA` behaves differently in certain operations. In addition to arithmetic operations, `pd.NA` also propagates as “missing” or “unknown” in comparison operations:

```
In [6]: np.nan > 1
```

```
Out[6]: False
```

```
In [7]: pd.NA > 1
```

```
Out[7]: <NA>
```

For logical operations, `pd.NA` follows the rules of the [three-valued logic](#) (or *Kleene logic*). For example:

```
In [8]: pd.NA | True
```

```
Out[8]: True
```

For more, see [NA section](#) in the user guide on missing data.

1.3.2 Dedicated string data type

We've added `StringDtype`, an extension type dedicated to string data. Previously, strings were typically stored in object-dtype NumPy arrays. ([GH29975](#))

Warning: `StringDtype` is currently considered experimental. The implementation and parts of the API may change without warning.

The '`string`' extension type solves several issues with object-dtype NumPy arrays:

1. You can accidentally store a *mixture* of strings and non-strings in an `object` dtype array. A `StringArray` can only store strings.
2. `object` dtype breaks dtype-specific operations like `DataFrame.select_dtypes()`. There isn't a clear way to select *just* text while excluding non-text, but still `object`-dtype columns.
3. When reading code, the contents of an `object` dtype array is less clear than `string`.

```
In [9]: pd.Series(['abc', None, 'def'], dtype=pd.StringDtype())
```

```
Out[9]:
```

```
0      abc
```

```
1    <NA>
```

```
2      def
```

```
Length: 3, dtype: string
```

You can use the alias "`string`" as well.

```
In [10]: s = pd.Series(['abc', None, 'def'], dtype="string")
```

```
In [11]: s
```

```
Out[11]:
```

```
0      abc
```

```
1    <NA>
```

```
2      def
```

```
Length: 3, dtype: string
```

The usual string accessor methods work. Where appropriate, the return type of the Series or columns of a DataFrame will also have `string` dtype.

```
In [12]: s.str.upper()
```

```
Out[12]:
```

```
0      ABC
```

(continues on next page)

(continued from previous page)

```
1      <NA>
2      DEF
Length: 3, dtype: string

In [13]: s.str.split('b', expand=True).dtypes
Out[13]:
0    string
1    string
Length: 2, dtype: object
```

String accessor methods returning integers will return a value with Int64Dtype

```
In [14]: s.str.count("a")
Out[14]:
0      1
1      <NA>
2      0
Length: 3, dtype: Int64
```

We recommend explicitly using the string data type when working with strings. See [Text Data Types](#) for more.

1.3.3 Boolean data type with missing values support

We've added BooleanDtype / BooleanArray, an extension type dedicated to boolean data that can hold missing values. The default bool data type based on a bool-dtype NumPy array, the column can only hold True or False, and not missing values. This new BooleanArray can store missing values as well by keeping track of this in a separate mask. ([GH29555](#), [GH30095](#), [GH31131](#))

```
In [15]: pd.Series([True, False, None], dtype=pd.BooleanDtype())
Out[15]:
0      True
1     False
2      <NA>
Length: 3, dtype: boolean
```

You can use the alias "boolean" as well.

```
In [16]: s = pd.Series([True, False, None], dtype="boolean")

In [17]: s
Out[17]:
0      True
1     False
2      <NA>
Length: 3, dtype: boolean
```

1.3.4 convert_dtypes method to ease use of supported extension dtypes

In order to encourage use of the extension dtypes `StringDtype`, `BooleanDtype`, `Int64Dtype`, `Int32Dtype`, etc., that support `pd.NA`, the methods `DataFrame.convert_dtypes()` and `Series.convert_dtypes()` have been introduced. ([GH29752](#)) ([GH30929](#))

Example:

```
In [18]: df = pd.DataFrame({'x': ['abc', None, 'def'],
....:                         'y': [1, 2, np.nan],
....:                         'z': [True, False, True]})
....:

In [19]: df
Out[19]:
      x      y      z
0  abc  1.0   True
1  None  2.0  False
2  def   NaN   True

[3 rows x 3 columns]

In [20]: df.dtypes
Out[20]:
x    object
y    float64
z     bool
Length: 3, dtype: object
```

```
In [21]: converted = df.convert_dtypes()

In [22]: converted
Out[22]:
      x      y      z
0  abc     1   True
1  <NA>     2  False
2  def  <NA>   True

[3 rows x 3 columns]

In [23]: converted.dtypes
Out[23]:
x    string
y    Int64
z    boolean
Length: 3, dtype: object
```

This is especially useful after reading in data using readers such as `read_csv()` and `read_excel()`. See [here](#) for a description.

1.4 Other enhancements

- `DataFrame.to_string()` added the `max_colwidth` parameter to control when wide columns are truncated ([GH9784](#))
- Added the `na_value` argument to `Series.to_numpy()`, `Index.to_numpy()` and `DataFrame.to_numpy()` to control the value used for missing data ([GH30322](#))
- `MultiIndex.from_product()` infers level names from inputs if not explicitly provided ([GH27292](#))
- `DataFrame.to_latex()` now accepts `caption` and `label` arguments ([GH25436](#))
- DataFrames with *nullable integer*, the *new string dtype* and period data type can now be converted to pyarrow ($\geq 0.15.0$), which means that it is supported in writing to the Parquet file format when using the pyarrow engine ([GH28368](#)). Full roundtrip to parquet (writing and reading back in with `to_parquet()` / `read_parquet()`) is supported starting with pyarrow ≥ 0.16 ([GH20612](#)).
- `to_parquet()` now appropriately handles the `schema` argument for user defined schemas in the pyarrow engine. ([GH30270](#))
- `DataFrame.to_json()` now accepts an `indent` integer argument to enable pretty printing of JSON output ([GH12004](#))
- `read_stata()` can read Stata 119 dta files. ([GH28250](#))
- Implemented `pandas.core.window.Window.var()` and `pandas.core.window.Window.std()` functions ([GH26597](#))
- Added encoding argument to `DataFrame.to_string()` for non-ascii text ([GH28766](#))
- Added encoding argument to `DataFrame.to_html()` for non-ascii text ([GH28663](#))
- `Styler.background_gradient()` now accepts `vmin` and `vmax` arguments ([GH12145](#))
- `Styler.format()` added the `na_rep` parameter to help format the missing values ([GH21527](#), [GH28358](#))
- `read_excel()` now can read binary Excel (.xlsb) files by passing `engine='pyxlsb'`. For more details and example usage, see the *Binary Excel files documentation*. Closes [GH8540](#).
- The `partition_cols` argument in `DataFrame.to_parquet()` now accepts a string ([GH27117](#))
- `pandas.read_json()` now parses NaN, Infinity and -Infinity ([GH12213](#))
- DataFrame constructor preserve *ExtensionArray* dtype with *ExtensionArray* ([GH11363](#))
- `DataFrame.sort_values()` and `Series.sort_values()` have gained `ignore_index` keyword to be able to reset index after sorting ([GH30114](#))
- `DataFrame.sort_index()` and `Series.sort_index()` have gained `ignore_index` keyword to reset index ([GH30114](#))
- `DataFrame.drop_duplicates()` has gained `ignore_index` keyword to reset index ([GH30114](#))
- Added new writer for exporting Stata dta files in versions 118 and 119, `StataWriterUTF8`. These files formats support exporting strings containing Unicode characters. Format 119 supports data sets with more than 32,767 variables ([GH23573](#), [GH30959](#))
- `Series.map()` now accepts `collections.abc.Mapping` subclasses as a mapper ([GH29733](#))
- Added an experimental `attrs` for storing global metadata about a dataset ([GH29062](#))
- `Timestamp.fromisocalendar()` is now compatible with python 3.8 and above ([GH28115](#))
- `DataFrame.to_pickle()` and `read_pickle()` now accept URL ([GH30163](#))

1.5 Backwards incompatible API changes

1.5.1 Avoid using names from MultiIndex.levels

As part of a larger refactor to MultiIndex the level names are now stored separately from the levels (GH27242). We recommend using MultiIndex.names to access the names, and Index.set_names() to update the names.

For backwards compatibility, you can still access the names via the levels.

```
In [24]: mi = pd.MultiIndex.from_product([[1, 2], ['a', 'b']], names=['x', 'y'])

In [25]: mi.levels[0].name
Out[25]: 'x'
```

However, it is no longer possible to *update* the names of the MultiIndex via the level.

```
In [26]: mi.levels[0].name = "new name"
-----
RuntimeError                                     Traceback (most recent call last)
<ipython-input-26-65f4400a0c97> in <module>
----> 1 mi.levels[0].name = "new name"

/pandas/pandas/core/indexes/base.py in name(self, value)
    1189         # Used in MultiIndex.levels to avoid silently ignoring name
    1190     updates.
-> 1191         raise RuntimeError(
    1192             "Cannot set name on a level of a MultiIndex. Use "
    1193             "'MultiIndex.set_names' instead."
    1194         )

RuntimeError: Cannot set name on a level of a MultiIndex. Use 'MultiIndex.set_names' instead.

In [27]: mi.names
Out[27]: FrozenList(['x', 'y'])
```

To update, use MultiIndex.set_names, which returns a new MultiIndex.

```
In [28]: mi2 = mi.set_names("new name", level=0)

In [29]: mi2.names
Out[29]: FrozenList(['new name', 'y'])
```

1.5.2 New repr for IntervalArray

`pandas.arrays.IntervalArray` adopts a new `__repr__` in accordance with other array classes (GH25022)
`pandas 0.25.x`

```
In [1]: pd.arrays.IntervalArray.from_tuples([(0, 1), (2, 3)])
Out[2]:
IntervalArray([(0, 1), (2, 3)],
              closed='right',
              dtype='interval[int64]')
```

`pandas 1.0.0`

```
In [30]: pd.arrays.IntervalArray.from_tuples([(0, 1), (2, 3)])
Out[30]:
<IntervalArray>
[(0, 1], (2, 3]]
Length: 2, closed: right, dtype: interval[int64]
```

1.5.3 DataFrame.rename now only accepts one positional argument

`DataFrame.rename()` would previously accept positional arguments that would lead to ambiguous or undefined behavior. From pandas 1.0, only the very first argument, which maps labels to their new names along the default axis, is allowed to be passed by position ([GH29136](#)).

pandas 0.25.x

```
>>> df = pd.DataFrame([[1]])
>>> df.rename({0: 1}, {0: 2})
FutureWarning: ...Use named arguments to resolve ambiguity...
    2
   1  1
```

pandas 1.0.0

```
>>> df.rename({0: 1}, {0: 2})
Traceback (most recent call last):
...
TypeError: rename() takes from 1 to 2 positional arguments but 3 were given
```

Note that errors will now be raised when conflicting or potentially ambiguous arguments are provided.

pandas 0.25.x

```
>>> df.rename({0: 1}, index={0: 2})
    0
   1  1

>>> df.rename(mapper={0: 1}, index={0: 2})
    0
   2  1
```

pandas 1.0.0

```
>>> df.rename({0: 1}, index={0: 2})
Traceback (most recent call last):
...
TypeError: Cannot specify both 'mapper' and any of 'index' or 'columns'

>>> df.rename(mapper={0: 1}, index={0: 2})
Traceback (most recent call last):
...
TypeError: Cannot specify both 'mapper' and any of 'index' or 'columns'
```

You can still change the axis along which the first positional argument is applied by supplying the `axis` keyword argument.

```
In [31]: df.rename({0: 1})
Out[31]:
```

(continues on next page)

(continued from previous page)

```

0
1 1

[1 rows x 1 columns]

In [32]: df.rename({0: 1}, axis=1)
Out[32]:
1
0 1

[1 rows x 1 columns]

```

If you would like to update both the index and column labels, be sure to use the respective keywords.

```

In [33]: df.rename(index={0: 1}, columns={0: 2})
Out[33]:
2
1 1

[1 rows x 1 columns]

```

1.5.4 Extended verbose info output for DataFrame

`DataFrame.info()` now shows line numbers for the columns summary (GH17304)

pandas 0.25.x

```

>>> df = pd.DataFrame({"int_col": [1, 2, 3],
...                     "text_col": ["a", "b", "c"],
...                     "float_col": [0.0, 0.1, 0.2]})
>>> df.info(verbose=True)
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 3 entries, 0 to 2
Data columns (total 3 columns):

dtypes: float64(1), int64(1), object(1)
memory usage: 200.0+ bytes
```

1.5.5 pandas.array() inference changes

`pandas.array()` now infers pandas' new extension types in several cases (GH29791):

1. String data (including missing values) now returns a `arrays.StringArray`.
2. Integer data (including missing values) now returns a `arrays.IntegerArray`.
3. Boolean data (including missing values) now returns the new `arrays.BooleanArray`

pandas 0.25.x

```
>>> pd.array(["a", None])
<PandasArray>
['a', None]
Length: 2, dtype: object

>>> pd.array([1, None])
<PandasArray>
[1, None]
Length: 2, dtype: object
```

pandas 1.0.0

```
In [36]: pd.array(["a", None])
Out[36]:
<StringArray>
['a', <NA>]
Length: 2, dtype: string

In [37]: pd.array([1, None])
Out[37]:
<IntegerArray>
[1, <NA>]
Length: 2, dtype: Int64
```

As a reminder, you can specify the `dtype` to disable all inference.

1.5.6 arrays.IntegerArray now uses pandas.NA

`arrays.IntegerArray` now uses `pandas.NA` rather than `numpy.nan` as its missing value marker (GH29964).

pandas 0.25.x

```
>>> a = pd.array([1, 2, None], dtype="Int64")
>>> a
<IntegerArray>
[1, 2, NaN]
Length: 3, dtype: Int64

>>> a[2]
nan
```

pandas 1.0.0

```
In [38]: a = pd.array([1, 2, None], dtype="Int64")
In [39]: a
Out[39]:
<IntegerArray>
[1, 2, <NA>]
Length: 3, dtype: Int64
In [40]: a[2]
Out[40]: <NA>
```

This has a few API-breaking consequences.

Converting to a NumPy ndarray

When converting to a NumPy array missing values will be `pd.NA`, which cannot be converted to a float. So calling `np.asarray(integer_array, dtype="float")` will now raise.

pandas 0.25.x

```
>>> np.asarray(a, dtype="float")
array([1., 2., nan])
```

pandas 1.0.0

```
In [41]: np.asarray(a, dtype="float")
-----
ValueError                                                 Traceback (most recent call last)
<ipython-input-41-4578f04da2b3> in <module>
----> 1 np.asarray(a, dtype="float")

/opt/conda/envs/pandas/lib/python3.7/site-packages/numpy/core/_asarray.py in
    ↪asarray(a, dtype, order)
    83
    84     """
----> 85     return array(a, dtype, copy=False, order=order)
    86
    87

/pandas/pandas/core/arrays/masked.py in __array__(self, dtype)
    143         We return an object array here to preserve our scalar values
    144         """
--> 145         return self.to_numpy(dtype=dtype)
    146
    147     def __arrow_array__(self, type=None):

/pandas/pandas/core/arrays/masked.py in to_numpy(self, dtype, copy, na_value)
    125         ):
    126             raise ValueError(
--> 127                 f"cannot convert to '{dtype}'-dtype NumPy array "
    128                     "with missing values. Specify an appropriate 'na_value' "
    129                     "for this dtype."
    130

ValueError: cannot convert to 'float64'-dtype NumPy array with missing values.
    ↪Specify an appropriate 'na_value' for this dtype.
```

Use `arrays.IntegerArray.to_numpy()` with an explicit `na_value` instead.

```
In [42]: a.to_numpy(dtype="float", na_value=np.nan)
Out[42]: array([ 1.,  2., nan])
```

Reductions can return ``pd.NA``

When performing a reduction such as a sum with `skipna=False`, the result will now be `pd.NA` instead of `np.nan` in presence of missing values ([GH30958](#)).

pandas 0.25.x

```
>>> pd.Series(a).sum(skipna=False)
nan
```

pandas 1.0.0

```
In [43]: pd.Series(a).sum(skipna=False)
Out[43]: <NA>
```

value_counts returns a nullable integer dtype

`Series.value_counts()` with a nullable integer dtype now returns a nullable integer dtype for the values.

pandas 0.25.x

```
>>> pd.Series([2, 1, 1, None], dtype="Int64").value_counts().dtype
dtype('int64')
```

pandas 1.0.0

```
In [44]: pd.Series([2, 1, 1, None], dtype="Int64").value_counts().dtype
Out[44]: Int64Dtype()
```

See [Experimental NA scalar to denote missing values](#) for more on the differences between `pandas.NA` and `numpy.nan`.

1.5.7 arrays.IntegerArray comparisons return arrays.BooleanArray

Comparison operations on a `arrays.IntegerArray` now returns a `arrays.BooleanArray` rather than a NumPy array ([GH29964](#)).

pandas 0.25.x

```
>>> a = pd.array([1, 2, None], dtype="Int64")
>>> a
<IntegerArray>
[1, 2, NaN]
Length: 3, dtype: Int64

>>> a > 1
array([False,  True, False])
```

pandas 1.0.0

```
In [45]: a = pd.array([1, 2, None], dtype="Int64")
In [46]: a > 1
Out[46]:
```

(continues on next page)

(continued from previous page)

```
<BooleanArray>
[False, True, <NA>]
Length: 3, dtype: boolean
```

Note that missing values now propagate, rather than always comparing unequal like `numpy.nan`. See [Experimental NA scalar to denote missing values](#) for more.

1.5.8 By default `Categorical.min()` now returns the minimum instead of `np.nan`

When `Categorical` contains `np.nan`, `Categorical.min()` no longer return `np.nan` by default (`skipna=True`) ([GH25303](#))

pandas 0.25.x

```
In [1]: pd.Categorical([1, 2, np.nan], ordered=True).min()
Out[1]: nan
```

pandas 1.0.0

```
In [47]: pd.Categorical([1, 2, np.nan], ordered=True).min()
Out[47]: 1
```

1.5.9 Default dtype of empty `pandas.Series`

Initialising an empty `pandas.Series` without specifying a dtype will raise a `DeprecationWarning` now ([GH17261](#)). The default dtype will change from `float64` to `object` in future releases so that it is consistent with the behaviour of `DataFrame` and `Index`.

pandas 1.0.0

```
In [1]: pd.Series()
Out[2]:
DeprecationWarning: The default dtype for empty Series will be 'object' instead of
'float64' in a future version. Specify a dtype explicitly to silence this warning.
Series([], dtype: float64)
```

1.5.10 Result dtype inference changes for resample operations

The rules for the result dtype in `DataFrame.resample()` aggregations have changed for extension types ([GH31359](#)). Previously, pandas would attempt to convert the result back to the original dtype, falling back to the usual inference rules if that was not possible. Now, pandas will only return a result of the original dtype if the scalar values in the result are instances of the extension dtype's scalar type.

```
In [48]: df = pd.DataFrame({'A': ['a', 'b']}, dtype='category',
....:                     index=pd.date_range('2000', periods=2))
....:

In [49]: df
Out[49]:
          A
2000-01-01 a
2000-01-02 b
```

(continues on next page)

(continued from previous page)

```
[2 rows x 1 columns]
```

pandas 0.25.x

```
>>> df.resample("2D").agg(lambda x: 'a').A.dtype  
CategoricalDtype(categories=['a', 'b'], ordered=False)
```

pandas 1.0.0

```
In [50]: df.resample("2D").agg(lambda x: 'a').A.dtype  
Out[50]: dtype('O')
```

This fixes an inconsistency between `resample` and `groupby`. This also fixes a potential bug, where the **values** of the result might change depending on how the results are cast back to the original `dtype`.

pandas 0.25.x

```
>>> df.resample("2D").agg(lambda x: 'c')  
  
          A  
0    NaN
```

pandas 1.0.0

```
In [51]: df.resample("2D").agg(lambda x: 'c')  
Out[51]:  
          A  
2000-01-01    c  
  
[1 rows x 1 columns]
```

1.5.11 Increased minimum version for Python

Pandas 1.0.0 supports Python 3.6.1 and higher ([GH29212](#)).

1.5.12 Increased minimum versions for dependencies

Some minimum supported versions of dependencies were updated ([GH29766](#), [GH29723](#)). If installed, we now require:

Package	Minimum Version	Required	Changed
numpy	1.13.3	X	
pytz	2015.4	X	
python-dateutil	2.6.1	X	
bottleneck	1.2.1		
numexpr	2.6.2		
pytest (dev)	4.0.2		

For optional libraries the general recommendation is to use the latest version. The following table lists the lowest version per library that is currently being tested throughout the development of pandas. Optional libraries below the lowest tested version may still work, but are not considered supported.

Package	Minimum Version	Changed
beautifulsoup4	4.6.0	
fastparquet	0.3.2	X
gcsfs	0.2.2	
lxml	3.8.0	
matplotlib	2.2.2	
numba	0.46.0	X
openpyxl	2.5.7	X
pyarrow	0.13.0	X
pymysql	0.7.1	
pytables	3.4.2	
s3fs	0.3.0	X
scipy	0.19.0	
sqlalchemy	1.1.4	
xarray	0.8.2	
xlrd	1.1.0	
xlsxwriter	0.9.8	
xlwt	1.2.0	

See [Dependencies](#) and [Optional dependencies](#) for more.

1.5.13 Build Changes

Pandas has added a `pyproject.toml` file and will no longer include cythonized files in the source distribution uploaded to PyPI ([GH28341](#), [GH20775](#)). If you’re installing a built distribution (wheel) or via conda, this shouldn’t have any effect on you. If you’re building pandas from source, you should no longer need to install Cython into your build environment before calling `pip install pandas`.

1.5.14 Other API changes

- `core.groupby.GroupBy.transform` now raises on invalid operation names ([GH27489](#))
- `pandas.api.types.infer_dtype()` will now return “integer-na” for integer and `np.nan` mix ([GH27283](#))
- `MultiIndex.from_arrays()` will no longer infer names from arrays if `names=None` is explicitly provided ([GH27292](#))
- In order to improve tab-completion, Pandas does not include most deprecated attributes when introspecting a pandas object using `dir` (e.g. `dir(df)`). To see which attributes are excluded, see an object’s `_deprecations` attribute, for example `pd.DataFrame._deprecations` ([GH28805](#)).
- The returned `dtype` of `unique()` now matches the input `dtype`. ([GH27874](#))
- Changed the default configuration value for `options.matplotlib.register_converters` from `True` to “auto” ([GH18720](#)). Now, pandas custom formatters will only be applied to plots created by pandas, through `plot()`. Previously, pandas’ formatters would be applied to all plots created *after* a `plot()`. See [units registration](#) for more.
- `Series.dropna()` has dropped its `**kwargs` argument in favor of a single `how` parameter. Supplying anything else than `how` to `**kwargs` raised a `TypeError` previously ([GH29388](#))
- When testing pandas, the new minimum required version of pytest is 5.0.1 ([GH29664](#))
- `Series.str.__iter__()` was deprecated and will be removed in future releases ([GH28277](#)).

- Added <NA> to the list of default NA values for `read_csv()` (GH30821)

1.5.15 Documentation Improvements

- Added new section on *Scaling to large datasets* (GH28315).
- Added sub-section on *Query MultiIndex* for HDF5 datasets (GH28791).

1.6 Deprecations

- `Series.item()` and `Index.item()` have been `_undeprecated_` (GH29250)
- `Index.set_value` has been deprecated. For a given index `idx`, array `arr`, value in `idx` of `idx_val` and a new value of `val`, `idx.set_value(arr, idx_val, val)` is equivalent to `arr[idx.get_loc(idx_val)] = val`, which should be used instead (GH28621).
- `is_extension_type()` is deprecated, `is_extension_array_dtype()` should be used instead (GH29457)
- `eval()` keyword argument “`truediv`” is deprecated and will be removed in a future version (GH29812)
- `DateOffset.isAnchored()` and `DatetimeOffset.onOffset()` are deprecated and will be removed in a future version, use `DateOffset.is_anchored()` and `DateOffset.is_on_offset()` instead (GH30340)
- `pandas.tseries.frequencies.get_offset` is deprecated and will be removed in a future version, use `pandas.tseries.frequencies.to_offset` instead (GH4205)
- `Categorical.take_nd()` and `CategoricalIndex.take_nd()` are deprecated, use `Categorical.take()` and `CategoricalIndex.take()` instead (GH27745)
- The parameter `numeric_only` of `Categorical.min()` and `Categorical.max()` is deprecated and replaced with `skipna` (GH25303)
- The parameter `label` in `lreshape()` has been deprecated and will be removed in a future version (GH29742)
- `pandas.core.index` has been deprecated and will be removed in a future version, the public classes are available in the top-level namespace (GH19711)
- `pandas.json_normalize()` is now exposed in the top-level namespace. Usage of `json_normalize` as `pandas.io.json.json_normalize` is now deprecated and it is recommended to use `json_normalize` as `pandas.json_normalize()` instead (GH27586).
- The `numpy` argument of `pandas.read_json()` is deprecated (GH28512).
- `DataFrame.to_stata()`, `DataFrame.to_feather()`, and `DataFrame.to_parquet()` argument “`fname`” is deprecated, use “`path`” instead (GH23574)
- The deprecated internal attributes `_start`, `_stop` and `_step` of `RangeIndex` now raise a `FutureWarning` instead of a `DeprecationWarning` (GH26581)
- The `pandas.util.testing` module has been deprecated. Use the public API in `pandas.testing` documented at *Testing functions* (GH16232).
- `pandas.SparseArray` has been deprecated. Use `pandas.arrays.SparseArray` (`arrays.SparseArray`) instead. (GH30642)
- The parameter `is_copy` of `Series.take()` and `DataFrame.take()` has been deprecated and will be removed in a future version. (GH27357)

- Support for multi-dimensional indexing (e.g. `index[:, None]`) on a `Index` is deprecated and will be removed in a future version, convert to a numpy array before indexing instead ([GH30588](#))
- The `pandas.np` submodule is now deprecated. Import numpy directly instead ([GH30296](#))
- The `pandas.datetime` class is now deprecated. Import from `datetime` instead ([GH30610](#))
- `diff` will raise a `TypeError` rather than implicitly losing the `dtype` of extension types in the future. Convert to the correct `dtype` before calling `diff` instead ([GH31025](#))

Selecting Columns from a Grouped DataFrame

When selecting columns from a `DataFrameGroupBy` object, passing individual keys (or a tuple of keys) inside single brackets is deprecated, a list of items should be used instead. ([GH23566](#)) For example:

```
df = pd.DataFrame({
    "A": ["foo", "bar", "foo", "bar", "foo", "bar", "foo", "foo"],
    "B": np.random.randn(8),
    "C": np.random.randn(8),
})
g = df.groupby('A')

# single key, returns SeriesGroupBy
g['B']

# tuple of single key, returns SeriesGroupBy
g[('B', )]

# tuple of multiple keys, returns DataFrameGroupBy, raises FutureWarning
g[('B', 'C')]

# multiple keys passed directly, returns DataFrameGroupBy, raises FutureWarning
# (implicitly converts the passed strings into a single tuple)
g['B', 'C']

# proper way, returns DataFrameGroupBy
g[['B', 'C']]
```

1.7 Removal of prior version deprecations/changes

Removed SparseSeries and SparseDataFrame

`SparseSeries`, `SparseDataFrame` and the `DataFrame.to_sparse` method have been removed ([GH28425](#)). We recommend using a `Series` or `DataFrame` with sparse values instead. See [Migrating](#) for help with migrating existing code.

Matplotlib unit registration

Previously, pandas would register converters with matplotlib as a side effect of importing pandas ([GH18720](#)). This changed the output of plots made via matplotlib plots after pandas was imported, even if you were using matplotlib directly rather than `plot()`.

To use pandas formatters with a matplotlib plot, specify

```
>>> import pandas as pd
>>> pd.options.plotting.matplotlib.register_converters = True
```

Note that plots created by `DataFrame.plot()` and `Series.plot()` *do* register the converters automatically. The only behavior change is when plotting a date-like object via `matplotlib.pyplot.plot` or `matplotlib.Axes.plot`. See [Custom formatters for timeseries plots](#) for more.

Other removals

- Removed the previously deprecated keyword “index” from `read_stata()`, `StataReader`, and `StataReader.read()`, use “`index_col`” instead ([GH17328](#))
- Removed `StataReader.data` method, use `StataReader.read()` instead ([GH9493](#))
- Removed `pandas.plotting._matplotlib.tsplot`, use `Series.plot()` instead ([GH19980](#))
- `pandas.tseries.converter.register` has been moved to `pandas.plotting.register_matplotlib_converters()` ([GH18307](#))
- `Series.plot()` no longer accepts positional arguments, pass keyword arguments instead ([GH30003](#))
- `DataFrame.hist()` and `Series.hist()` no longer allows `figsize="default"`, specify figure size by passing a tuple instead ([GH30003](#))
- Floordiv of integer-dtyped array by `Timedelta` now raises `TypeError` ([GH21036](#))
- `TimedeltaIndex` and `DatetimeIndex` no longer accept non-nanosecond dtype strings like “`timedelta64`” or “`datetime64`”, use “`timedelta64[ns]`” and “`datetime64[ns]`” instead ([GH24806](#))
- Changed the default “`skipna`” argument in `pandas.api.types.infer_dtype()` from `False` to `True` ([GH24050](#))
- Removed `Series.ix` and `DataFrame.ix` ([GH26438](#))
- Removed `Index.summary` ([GH18217](#))
- Removed the previously deprecated keyword “`fastpath`” from the `Index` constructor ([GH23110](#))
- Removed `Series.get_value`, `Series.set_value`, `DataFrame.get_value`, `DataFrame.set_value` ([GH17739](#))
- Removed `Series.compound` and `DataFrame.compound` ([GH26405](#))
- Changed the default “`inplace`” argument in `DataFrame.set_index()` and `Series.set_axis()` from `None` to `False` ([GH27600](#))
- Removed `Series.cat.categorical`, `Series.cat.index`, `Series.cat.name` ([GH24751](#))
- Removed the previously deprecated keyword “`box`” from `to_datetime()` and `to_timedelta()`; in addition these now always returns `DatetimeIndex`, `TimedeltaIndex`, `Index`, `Series`, or `DataFrame` ([GH24486](#))
- `to_timedelta()`, `Timedelta`, and `TimedeltaIndex` no longer allow “`M`”, “`y`”, or “`Y`” for the “`unit`” argument ([GH23264](#))
- Removed the previously deprecated keyword “`time_rule`” from (non-public) `offsets.generate_range`, which has been moved to `core.arrays._ranges.generate_range()` ([GH24157](#))
- `DataFrame.loc()` or `Series.loc()` with listlike indexers and missing labels will no longer reindex ([GH17295](#))
- `DataFrame.to_excel()` and `Series.to_excel()` with non-existent columns will no longer reindex ([GH17295](#))
- Removed the previously deprecated keyword “`join_axes`” from `concat()`; use `reindex_like` on the result instead ([GH22318](#))
- Removed the previously deprecated keyword “`by`” from `DataFrame.sort_index()`, use `DataFrame.sort_values()` instead ([GH10726](#))

- Removed support for nested renaming in `DataFrame.aggregate()`, `Series.aggregate()`, `core.groupby.DataFrameGroupBy.aggregate()`, `core.groupby.SeriesGroupBy.aggregate()`, `core.window.rolling.Rolling.aggregate()` ([GH18529](#))
- Passing `datetime64` data to `TimedeltaIndex` or `timedelta64` data to `DatetimeIndex` now raises `TypeError` ([GH23539](#), [GH23937](#))
- Passing `int64` values to `DatetimeIndex` and a timezone now interprets the values as nanosecond timestamps in UTC, not wall times in the given timezone ([GH24559](#))
- A tuple passed to `DataFrame.groupby()` is now exclusively treated as a single key ([GH18314](#))
- Removed `Index.contains`, `use` key in `index` instead ([GH30103](#))
- Addition and subtraction of `int` or `integer-arrays` is no longer allowed in `Timestamp`, `DatetimeIndex`, `TimedeltaIndex`, `use obj + n * obj.freq instead of obj + n` ([GH22535](#))
- Removed `Series.ptp` ([GH21614](#))
- Removed `Series.from_array` ([GH18258](#))
- Removed `DataFrame.from_items` ([GH18458](#))
- Removed `DataFrame.as_matrix`, `Series.as_matrix` ([GH18458](#))
- Removed `Series.asobject` ([GH18477](#))
- Removed `DataFrame.as_blocks`, `Series.as_blocks`, `DataFrame.blocks`, `Series.blocks` ([GH17656](#))
- `pandas.Series.str.cat()` now defaults to aligning others, using `join='left'` ([GH27611](#))
- `pandas.Series.str.cat()` does not accept list-likes *within* list-likes anymore ([GH27611](#))
- `Series.where()` with Categorical dtype (or `DataFrame.where()` with Categorical column) no longer allows setting new categories ([GH24114](#))
- Removed the previously deprecated keywords “start”, “end”, and “periods” from the `DatetimeIndex`, `TimedeltaIndex`, and `PeriodIndex` constructors; use `date_range()`, `timedelta_range()`, and `period_range()` instead ([GH23919](#))
- Removed the previously deprecated keyword “verify_integrity” from the `DatetimeIndex` and `TimedeltaIndex` constructors ([GH23919](#))
- Removed the previously deprecated keyword “fastpath” from `pandas.core.internals.blocks.make_block` ([GH19265](#))
- Removed the previously deprecated keyword “dtype” from `Block.make_block_same_class()` ([GH19434](#))
- Removed `ExtensionArray._formatting_values`. Use `ExtensionArray._formatter` instead. ([GH23601](#))
- Removed `MultiIndex.to_hierarchical` ([GH21613](#))
- Removed `MultiIndex.labels`, `use MultiIndex.codes instead` ([GH23752](#))
- Removed the previously deprecated keyword “labels” from the `MultiIndex` constructor, use “codes” instead ([GH23752](#))
- Removed `MultiIndex.set_labels`, `use MultiIndex.set_codes() instead` ([GH23752](#))
- Removed the previously deprecated keyword “labels” from `MultiIndex.set_codes()`, `MultiIndex.copy()`, `MultiIndex.drop()`, `use “codes” instead` ([GH23752](#))
- Removed support for legacy HDF5 formats ([GH29787](#))

- Passing a dtype alias (e.g. ‘datetime64[ns, UTC]’) to DatetimeTZDtype is no longer allowed, use DatetimeTZDtype.construct_from_string() instead ([GH23990](#))
- Removed the previously deprecated keyword “skip_footer” from read_excel(); use “skipfooter” instead ([GH18836](#))
- read_excel() no longer allows an integer value for the parameter usecols, instead pass a list of integers from 0 to usecols inclusive ([GH23635](#))
- Removed the previously deprecated keyword “convert_datetime64” from DataFrame.to_records() ([GH18902](#))
- Removed IntervalIndex.from_intervals in favor of the IntervalIndex constructor ([GH19263](#))
- Changed the default “keep_tz” argument in DatetimeIndex.to_series() from None to True ([GH23739](#))
- Removed api.types.is_period and api.types.is_datetimetz ([GH23917](#))
- Ability to read pickles containing Categorical instances created with pre-0.16 version of pandas has been removed ([GH27538](#))
- Removed pandas.tseries.plotting.tsplot ([GH18627](#))
- Removed the previously deprecated keywords “reduce” and “broadcast” from DataFrame.apply() ([GH18577](#))
- Removed the previously deprecated assert_raises_regex function in pandas._testing ([GH29174](#))
- Removed the previously deprecated FrozenNDArray class in pandas.core.indexes.frozen ([GH29335](#))
- Removed the previously deprecated keyword “nthreads” from read_feather(), use “use_threads” instead ([GH23053](#))
- Removed Index.is_lexsorted_for_tuple ([GH29305](#))
- Removed support for nested renaming in DataFrame.aggregate(), Series.aggregate(), core.groupby.DataFrameGroupBy.aggregate(), core.groupby.SeriesGroupBy.aggregate(), core.window.rolling.Rolling.aggregate() ([GH29608](#))
- Removed Series.valid; use Series.dropna() instead ([GH18800](#))
- Removed DataFrame.is_copy, Series.is_copy ([GH18812](#))
- Removed DataFrame.get_ftype_counts, Series.get_ftype_counts ([GH18243](#))
- Removed DataFrame.ftypes, Series.ftypes, Series.ftype ([GH26744](#))
- Removed Index.get_duplicates, use idx[idx.duplicated()].unique() instead ([GH20239](#))
- Removed Series.clip_upper, Series.clip_lower, DataFrame.clip_upper, DataFrame.clip_lower ([GH24203](#))
- Removed the ability to alter DatetimeIndex.freq, TimedeltaIndex.freq, or PeriodIndex.freq ([GH20772](#))
- Removed DatetimeIndex.offset ([GH20730](#))
- Removed DatetimeIndex.asobject, TimedeltaIndex.asobject, PeriodIndex.asobject, use astype(object) instead ([GH29801](#))
- Removed the previously deprecated keyword “order” from factorize() ([GH19751](#))
- Removed the previously deprecated keyword “encoding” from read_stata() and DataFrame.to_stata() ([GH21400](#))

- Changed the default “sort” argument in `concat()` from `None` to `False` ([GH20613](#))
- Removed the previously deprecated keyword “`raise_conflict`” from `DataFrame.update()`, use “`errors`” instead ([GH23585](#))
- Removed the previously deprecated keyword “`n`” from `DatetimeIndex.shift()`, `TimedeltaIndex.shift()`, `PeriodIndex.shift()`, use “`periods`” instead ([GH22458](#))
- Removed the previously deprecated keywords “`how`”, “`fill_method`”, and “`limit`” from `DataFrame.resample()` ([GH30139](#))
- Passing an integer to `Series.fillna()` or `DataFrame.fillna()` with `timedelta64[ns]` `dtype` now raises `TypeError` ([GH24694](#))
- Passing multiple axes to `DataFrame.dropna()` is no longer supported ([GH20995](#))
- Removed `Series.nonzero`, use `to_numpy().nonzero()` instead ([GH24048](#))
- Passing floating `dtype` codes to `Categorical.from_codes()` is no longer supported, pass `codes.astype(np.int64)` instead ([GH21775](#))
- Removed the previously deprecated keyword “`pat`” from `Series.str.partition()` and `Series.str.rpartition()`, use “`sep`” instead ([GH23767](#))
- Removed `Series.put` ([GH27106](#))
- Removed `Series.real`, `Series.imag` ([GH27106](#))
- Removed `Series.to_dense`, `DataFrame.to_dense` ([GH26684](#))
- Removed `Index.dtype_str`, use `str(index.dtype)` instead ([GH27106](#))
- `Categorical.ravel()` returns a `Categorical` instead of a `ndarray` ([GH27199](#))
- The ‘outer’ method on Numpy ufuncs, e.g. `np.subtract.outer` operating on `Series` objects is no longer supported, and will raise `NotImplementedError` ([GH27198](#))
- Removed `Series.get_dtype_counts` and `DataFrame.get_dtype_counts` ([GH27145](#))
- Changed the default “`fill_value`” argument in `Categorical.take()` from `True` to `False` ([GH20841](#))
- Changed the default value for the `raw` argument in `Series.rolling().apply()`, `DataFrame.rolling().apply()`, `Series.expanding().apply()`, and `DataFrame.expanding().apply()` from `None` to `False` ([GH20584](#))
- Removed deprecated behavior of `Series.argmin()` and `Series.argmax()`, use `Series.idxmin()` and `Series.idxmax()` for the old behavior ([GH16955](#))
- Passing a tz-aware `datetime.datetime` or `Timestamp` into the `Timestamp` constructor with the `tz` argument now raises a `ValueError` ([GH23621](#))
- Removed `Series.base`, `Index.base`, `Categorical.base`, `Series.flags`, `Index.flags`, `PeriodArray.flags`, `Series.strides`, `Index.strides`, `Series.itemsize`, `Index.itemsize`, `Series.data`, `Index.data` ([GH20721](#))
- Changed `Timedelta.resolution()` to match the behavior of the standard library `datetime.timedelta.resolution`, for the old behavior, use `Timedelta.resolution_string()` ([GH26839](#))
- Removed `Timestamp.weekday_name`, `DatetimeIndex.weekday_name`, and `Series.dt.weekday_name` ([GH18164](#))
- Removed the previously deprecated keyword “`errors`” in `Timestamp.tz_localize()`, `DatetimeIndex.tz_localize()`, and `Series.tz_localize()` ([GH22644](#))
- Changed the default “`ordered`” argument in `CategoricalDtype` from `None` to `False` ([GH26336](#))

- `Series.set_axis()` and `DataFrame.set_axis()` now require “labels” as the first argument and “axis” as an optional named parameter ([GH30089](#))
- Removed `to_msgpack`, `read_msgpack`, `DataFrame.to_msgpack`, `Series.to_msgpack` ([GH27103](#))
- Removed `Series.compress` ([GH21930](#))
- Removed the previously deprecated keyword “fill_value” from `Categorical.fillna()`, use “value” instead ([GH19269](#))
- Removed the previously deprecated keyword “data” from `andrews_curves()`, use “frame” instead ([GH6956](#))
- Removed the previously deprecated keyword “data” from `parallel_coordinates()`, use “frame” instead ([GH6956](#))
- Removed the previously deprecated keyword “colors” from `parallel_coordinates()`, use “color” instead ([GH6956](#))
- Removed the previously deprecated keywords “verbose” and “private_key” from `read_gbq()` ([GH30200](#))
- Calling `np.array` and `np.asarray` on tz-aware Series and DatetimeIndex will now return an object array of tz-aware Timestamp ([GH24596](#))
-

1.8 Performance improvements

- Performance improvement in DataFrame arithmetic and comparison operations with scalars ([GH24990](#), [GH29853](#))
- Performance improvement in indexing with a non-unique IntervalIndex ([GH27489](#))
- Performance improvement in MultiIndex.is_monotonic ([GH27495](#))
- Performance improvement in `cut()` when bins is an IntervalIndex ([GH27668](#))
- Performance improvement when initializing a DataFrame using a range ([GH30171](#))
- Performance improvement in `DataFrame.corr()` when method is "spearman" ([GH28139](#))
- Performance improvement in `DataFrame.replace()` when provided a list of values to replace ([GH28099](#))
- Performance improvement in `DataFrame.select_dtypes()` by using vectorization instead of iterating over a loop ([GH28317](#))
- Performance improvement in `Categorical.searchsorted()` and `CategoricalIndex.searchsorted()` ([GH28795](#))
- Performance improvement when comparing a Categorical with a scalar and the scalar is not found in the categories ([GH29750](#))
- Performance improvement when checking if values in a Categorical are equal, equal or larger or larger than a given scalar. The improvement is not present if checking if the Categorical is less than or less than or equal than the scalar ([GH29820](#))
- Performance improvement in `Index.equals()` and `MultiIndex.equals()` ([GH29134](#))
- Performance improvement in `infer_dtype()` when skipna is True ([GH28814](#))

1.9 Bug fixes

1.9.1 Categorical

- Added test to assert the `fillna()` raises the correct `ValueError` message when the value isn't a value from categories ([GH13628](#))
- Bug in `Categorical.astype()` where `Nan` values were handled incorrectly when casting to `int` ([GH28406](#))
- `DataFrame.reindex()` with a `CategoricalIndex` would fail when the targets contained duplicates, and wouldn't fail if the source contained duplicates ([GH28107](#))
- Bug in `Categorical.astype()` not allowing for casting to extension dtypes ([GH28668](#))
- Bug where `merge()` was unable to join on categorical and extension dtype columns ([GH28668](#))
- `Categorical.searchsorted()` and `CategoricalIndex.searchsorted()` now work on un-ordered categoricals also ([GH21667](#))
- Added test to assert roundtripping to parquet with `DataFrame.to_parquet()` or `read_parquet()` will preserve Categorical dtypes for string types ([GH27955](#))
- Changed the error message in `Categorical.remove_categories()` to always show the invalid removals as a set ([GH28669](#))
- Using date accessors on a categorical dtypes `Series` of datetimes was not returning an object of the same type as if one used the `str.()` / `dt.()` on a `Series` of that type. E.g. when accessing `Series.dt.tz_localize()` on a `Categorical` with duplicate entries, the accessor was skipping duplicates ([GH27952](#))
- Bug in `DataFrame.replace()` and `Series.replace()` that would give incorrect results on categorical data ([GH26988](#))
- Bug where calling `Categorical.min()` or `Categorical.max()` on an empty `Categorical` would raise a numpy exception ([GH30227](#))
- The following methods now also correctly output values for unobserved categories when called through `groupby(..., observed=False)` ([GH17605](#)) * `core.groupby.SeriesGroupBy.count()` * `core.groupby.SeriesGroupBy.size()` * `core.groupby.SeriesGroupBy.nunique()` * `core.groupby.SeriesGroupBy.nth()`

1.9.2 Datetimelike

- Bug in `Series.__setitem__()` incorrectly casting `np.timedelta64("NaT")` to `np.datetime64("NaT")` when inserting into a `Series` with `datetime64` dtype ([GH27311](#))
- Bug in `Series.dt()` property lookups when the underlying data is read-only ([GH27529](#))
- Bug in `HDFStore.__getitem__` incorrectly reading `tz` attribute created in Python 2 ([GH26443](#))
- Bug in `to_datetime()` where passing arrays of malformed `str` with `errors="coerce"` could incorrectly lead to raising `ValueError` ([GH28299](#))
- Bug in `core.groupby.SeriesGroupBy.nunique()` where `NaT` values were interfering with the count of unique values ([GH27951](#))
- Bug in `Timestamp` subtraction when subtracting a `Timestamp` from a `np.datetime64` object incorrectly raising `TypeError` ([GH28286](#))

- Addition and subtraction of integer or integer-dtype arrays with `Timestamp` will now raise `NullFrequencyError` instead of `ValueError` ([GH28268](#))
- Bug in `Series` and `DataFrame` with integer dtype failing to raise `TypeError` when adding or subtracting a `np.datetime64` object ([GH28080](#))
- Bug in `Series.astype()`, `Index.astype()`, and `DataFrame.astype()` failing to handle `NaT` when casting to an integer dtype ([GH28492](#))
- Bug in `Week` with `weekday` incorrectly raising `AttributeError` instead of `TypeError` when adding or subtracting an invalid type ([GH28530](#))
- Bug in `DataFrame` arithmetic operations when operating with a `Series` with dtype '`timedelta64[ns]`' ([GH28049](#))
- Bug in `core.groupby.generic.SeriesGroupBy.apply()` raising `ValueError` when a column in the original `DataFrame` is a datetime and the column labels are not standard integers ([GH28247](#))
- Bug in `pandas._config.localization.get_locales()` where the locales `-a` encodes the locales list as windows-1252 ([GH23638](#), [GH24760](#), [GH27368](#))
- Bug in `Series.var()` failing to raise `TypeError` when called with `timedelta64[ns]` dtype ([GH28289](#))
- Bug in `DatetimeIndex.strftime()` and `Series.dt.strftime()` where `NaT` was converted to the string '`NaT`' instead of `np.nan` ([GH29578](#))
- Bug in masking datetime-like arrays with a boolean mask of an incorrect length not raising an `IndexError` ([GH30308](#))
- Bug in `Timestamp.resolution` being a property instead of a class attribute ([GH29910](#))
- Bug in `pandas.to_datetime()` when called with `None` raising `TypeError` instead of returning `NaT` ([GH30011](#))
- Bug in `pandas.to_datetime()` failing for `deques` when using `cache=True` (the default) ([GH29403](#))
- Bug in `Series.item()` with `datetime64` or `timedelta64` dtype, `DatetimeIndex.item()`, and `TimedeltaIndex.item()` returning an integer instead of a `Timestamp` or `Timedelta` ([GH30175](#))
- Bug in `DatetimeIndex` addition when adding a non-optimized `DateOffset` incorrectly dropping timezone information ([GH30336](#))
- Bug in `DataFrame.drop()` where attempting to drop non-existent values from a `DatetimeIndex` would yield a confusing error message ([GH30399](#))
- Bug in `DataFrame.append()` would remove the timezone-awareness of new data ([GH30238](#))
- Bug in `Series.cummin()` and `Series.cummax()` with timezone-aware dtype incorrectly dropping its timezone ([GH15553](#))
- Bug in `DatetimeArray`, `TimedeltaArray`, and `PeriodArray` where `inplace` addition and subtraction did not actually operate `inplace` ([GH24115](#))
- Bug in `pandas.to_datetime()` when called with `Series` storing `IntegerArray` raising `TypeError` instead of returning `Series` ([GH30050](#))
- Bug in `date_range()` with custom business hours as `freq` and given number of periods ([GH30593](#))
- Bug in `PeriodIndex` comparisons with incorrectly casting integers to `Period` objects, inconsistent with the `Period` comparison behavior ([GH30722](#))
- Bug in `DatetimeIndex.insert()` raising a `ValueError` instead of a `TypeError` when trying to insert a timezone-aware `Timestamp` into a timezone-naive `DatetimeIndex`, or vice-versa ([GH30806](#))

1.9.3 Timedelta

- Bug in subtracting a TimedeltaIndex or TimedeltaArray from a np.datetime64 object (GH29558)
-
-

1.9.4 Timezones

-
-

1.9.5 Numeric

- Bug in DataFrame.quantile() with zero-column DataFrame incorrectly raising (GH23925)
- DataFrame flex inequality comparisons methods (DataFrame.lt(), DataFrame.le(), DataFrame.gt(), DataFrame.ge()) with object-dtype and complex entries failing to raise TypeError like their Series counterparts (GH28079)
- Bug in DataFrame logical operations (&, |, ^) not matching Series behavior by filling NA values (GH28741)
- Bug in DataFrame.interpolate() where specifying axis by name references variable before it is assigned (GH29142)
- Bug in Series.var() not computing the right value with a nullable integer dtype series not passing through ddof argument (GH29128)
- Improved error message when using *frac > 1* and *replace = False* (GH27451)
- Bug in numeric indexes resulted in it being possible to instantiate an Int64Index, UInt64Index, or Float64Index with an invalid dtype (e.g. datetime-like) (GH29539)
- Bug in UInt64Index precision loss while constructing from a list with values in the np.uint64 range (GH29526)
- Bug in NumericIndex construction that caused indexing to fail when integers in the np.uint64 range were used (GH28023)
- Bug in NumericIndex construction that caused UInt64Index to be casted to Float64Index when integers in the np.uint64 range were used to index a DataFrame (GH28279)
- Bug in Series.interpolate() when using method='index' with an unsorted index, would previously return incorrect results. (GH21037)
- Bug in DataFrame.round() where a DataFrame with a CategoricalIndex of IntervalIndex columns would incorrectly raise a TypeError (GH30063)
- Bug in Series.pct_change() and DataFrame.pct_change() when there are duplicated indices (GH30463)
- Bug in DataFrame cumulative operations (e.g. cumsum, cummax) incorrect casting to object-dtype (GH19296)
- Bug in diff losing the dtype for extension types (GH30889)
- Bug in DataFrame.diff raising an IndexError when one of the columns was a nullable integer dtype (GH30967)

1.9.6 Conversion

-
-

1.9.7 Strings

- Calling `Series.str.isalnum()` (and other “ismethods”) on an empty `Series` would return an `object` `dtype` instead of `bool` ([GH29624](#))
-

1.9.8 Interval

- Bug in `IntervalIndex.get_indexer()` where a `Categorical` or `CategoricalIndex` target would incorrectly raise a `TypeError` ([GH30063](#))
- Bug in `pandas.core.dtypes.cast.infer_dtype_from_scalar` where passing `pandas_dtype=True` did not infer `IntervalDtype` ([GH30337](#))
- Bug in `Series` constructor where constructing a `Series` from a list of `Interval` objects resulted in `object` `dtype` instead of `IntervalDtype` ([GH23563](#))
- Bug in `IntervalDtype` where the `kind` attribute was incorrectly set as `None` instead of "`O`" ([GH30568](#))
- Bug in `IntervalIndex`, `IntervalArray`, and `Series` with interval data where equality comparisons were incorrect ([GH24112](#))

1.9.9 Indexing

- Bug in assignment using a reverse slicer ([GH26939](#))
- Bug in `DataFrame.explode()` would duplicate frame in the presence of duplicates in the index ([GH28010](#))
- Bug in reindexing a `PeriodIndex()` with another type of index that contained a `Period` ([GH28323](#)) ([GH28337](#))
- Fix assignment of column via `.loc` with numpy non-ns datetime type ([GH27395](#))
- Bug in `Float64Index.astype()` where `np.inf` was not handled properly when casting to an integer `dtype` ([GH28475](#))
- `Index.union()` could fail when the left contained duplicates ([GH28257](#))
- Bug when indexing with `.loc` where the index was a `CategoricalIndex` with non-string categories didn't work ([GH17569](#), [GH30225](#))
- `Index.get_indexer_non_unique()` could fail with `TypeError` in some cases, such as when searching for ints in a string index ([GH28257](#))
- Bug in `Float64Index.get_loc()` incorrectly raising `TypeError` instead of `KeyError` ([GH29189](#))
- Bug in `DataFrame.loc()` with incorrect `dtype` when setting `Categorical` value in 1-row `DataFrame` ([GH25495](#))
- `MultiIndex.get_loc()` can't find missing values when input includes missing values ([GH19132](#))
- Bug in `Series.__setitem__()` incorrectly assigning values with boolean indexer when the length of new data matches the number of `True` values and new data is not a `Series` or an `np.array` ([GH30567](#))

- Bug in indexing with a `PeriodIndex` incorrectly accepting integers representing years, use e.g. `ser.loc["2007"]` instead of `ser.loc[2007]` ([GH30763](#))

1.9.10 Missing

-
-

1.9.11 MultiIndex

- Constructor for `MultiIndex` verifies that the given `sortorder` is compatible with the actual `lexsort_depth` if `verify_integrity` parameter is `True` (the default) ([GH28735](#))
- Series and `MultiIndex` `.drop` with `MultiIndex` raise exception if labels not in given in level ([GH8594](#))
-

1.9.12 I/O

- `read_csv()` now accepts binary mode file buffers when using the Python csv engine ([GH23779](#))
- Bug in `DataFrame.to_json()` where using a Tuple as a column or index value and using `orient="columns"` or `orient="index"` would produce invalid JSON ([GH20500](#))
- Improve infinity parsing. `read_csv()` now interprets `Infinity`, `+Infinity`, `-Infinity` as floating point values ([GH10065](#))
- Bug in `DataFrame.to_csv()` where values were truncated when the length of `na_rep` was shorter than the text input data. ([GH25099](#))
- Bug in `DataFrame.to_string()` where values were truncated using display options instead of outputting the full content ([GH9784](#))
- Bug in `DataFrame.to_json()` where a datetime column label would not be written out in ISO format with `orient="table"` ([GH28130](#))
- Bug in `DataFrame.to_parquet()` where writing to GCS would fail with `engine='fastparquet'` if the file did not already exist ([GH28326](#))
- Bug in `read_hdf()` closing stores that it didn't open when Exceptions are raised ([GH28699](#))
- Bug in `DataFrame.read_json()` where using `orient="index"` would not maintain the order ([GH28557](#))
- Bug in `DataFrame.to_html()` where the length of the `formatters` argument was not verified ([GH28469](#))
- Bug in `DataFrame.read_excel()` with `engine='ods'` when `sheet_name` argument references a non-existent sheet ([GH27676](#))
- Bug in `pandas.io.formats.style.Styler()` formatting for floating values not displaying decimals correctly ([GH13257](#))
- Bug in `DataFrame.to_html()` when using `formatters=<list>` and `max_cols` together. ([GH25955](#))
- Bug in `Styler.background_gradient()` not able to work with `dtype Int64` ([GH28869](#))
- Bug in `DataFrame.to_clipboard()` which did not work reliably in ipython ([GH22707](#))

- Bug in `read_json()` where default encoding was not set to `utf-8` ([GH29565](#))
- Bug in `PythonParser` where str and bytes were being mixed when dealing with the decimal field ([GH29650](#))
- `read_gbq()` now accepts `progress_bar_type` to display progress bar while the data downloads. ([GH29857](#))
- Bug in `pandas.io.json.json_normalize()` where a missing value in the location specified by `record_path` would raise a `TypeError` ([GH30148](#))
- `read_excel()` now accepts binary data ([GH15914](#))
- Bug in `read_csv()` in which encoding handling was limited to just the string `utf-16` for the C engine ([GH24130](#))

1.9.13 Plotting

- Bug in `Series.plot()` not able to plot boolean values ([GH23719](#))
- Bug in `DataFrame.plot()` not able to plot when no rows ([GH27758](#))
- Bug in `DataFrame.plot()` producing incorrect legend markers when plotting multiple series on the same axis ([GH18222](#))
- Bug in `DataFrame.plot()` when `kind='box'` and data contains datetime or timedelta data. These types are now automatically dropped ([GH22799](#))
- Bug in `DataFrame.plot.line()` and `DataFrame.plot.area()` produce wrong `xlim` in x-axis ([GH27686](#), [GH25160](#), [GH24784](#))
- Bug where `DataFrame.boxplot()` would not accept a `color` parameter like `DataFrame.plot.box()` ([GH26214](#))
- Bug in the `xticks` argument being ignored for `DataFrame.plot.bar()` ([GH14119](#))
- `set_option()` now validates that the plot backend provided to '`plotting.backend`' implements the backend when the option is set, rather than when a plot is created ([GH28163](#))
- `DataFrame.plot()` now allow a `backend` keyword argument to allow changing between backends in one session ([GH28619](#)).
- Bug in color validation incorrectly raising for non-color styles ([GH29122](#)).
- Allow `DataFrame.plot.scatter()` to plot objects and datetime type data ([GH18755](#), [GH30391](#))
- Bug in `DataFrame.hist()`, `xrot=0` does not work with `by` and `subplots` ([GH30288](#)).

1.9.14 Groupby/resample/rolling

- Bug in `core.groupby.DataFrameGroupBy.apply()` only showing output from a single group when function returns an `Index` ([GH28652](#))
- Bug in `DataFrame.groupby()` with multiple groups where an `IndexError` would be raised if any group contained all NA values ([GH20519](#))
- Bug in `pandas.core.resample.Resampler.size()` and `pandas.core.resample.Resampler.count()` returning wrong `dtype` when used with an empty Series or DataFrame ([GH28427](#))
- Bug in `DataFrame.rolling()` not allowing for rolling over datetimes when `axis=1` ([GH28192](#))
- Bug in `DataFrame.rolling()` not allowing rolling over multi-index levels ([GH15584](#)).

- Bug in DataFrame.rolling() not allowing rolling on monotonic decreasing time indexes (GH19248).
- Bug in DataFrame.groupby() not offering selection by column name when axis=1 (GH27614)
- Bug in core.groupby.DataFrameGroupby.agg() not able to use lambda function with named aggregation (GH27519)
- Bug in DataFrame.groupby() losing column name information when grouping by a categorical column (GH28787)
- Remove error raised due to duplicated input functions in named aggregation in DataFrame.groupby() and Series.groupby(). Previously error will be raised if the same function is applied on the same column and now it is allowed if new assigned names are different. (GH28426)
- core.groupby.SeriesGroupBy.value_counts() will be able to handle the case even when the Grouper makes empty groups (GH28479)
- Bug in core.window.rolling.Rolling.quantile() ignoring interpolation keyword argument when used within a groupby (GH28779)
- Bug in DataFrame.groupby() where any, all, nunique and transform functions would incorrectly handle duplicate column labels (GH21668)
- Bug in core.groupby.DataFrameGroupBy.agg() with timezone-aware datetime64 column incorrectly casting results to the original dtype (GH29641)
- Bug in DataFrame.groupby() when using axis=1 and having a single level columns index (GH30208)
- Bug in DataFrame.groupby() when using nunique on axis=1 (GH30253)
- Bug in GroupBy.quantile() with multiple list-like q value and integer column names (GH30289)
- Bug in GroupBy.pct_change() and core.groupby.SeriesGroupBy.pct_change() causes TypeError when fill_method is None (GH30463)
- Bug in Rolling.count() and Expanding.count() argument where min_periods was ignored (GH26996)

1.9.15 Reshaping

- Bug in DataFrame.apply() that caused incorrect output with empty DataFrame (GH28202, GH21959)
- Bug in DataFrame.stack() not handling non-unique indexes correctly when creating MultiIndex (GH28301)
- Bug in pivot_table() not returning correct type float when margins=True and aggfunc='mean' (GH24893)
- Bug merge_asof() could not use `datetime.timedelta` for tolerance kwarg (GH28098)
- Bug in merge(), did not append suffixes correctly with MultiIndex (GH28518)
- qcut() and cut() now handle boolean input (GH20303)
- Fix to ensure all int dtypes can be used in merge_asof() when using a tolerance value. Previously every non-int64 type would raise an erroneous MergeError (GH28870).
- Better error message in get_dummies() when *columns* isn't a list-like value (GH28383)
- Bug in Index.join() that caused infinite recursion error for mismatched MultiIndex name orders. (GH25760, GH28956)
- Bug Series.pct_change() where supplying an anchored frequency would throw a ValueError (GH28664)

- Bug where `DataFrame.equals()` returned True incorrectly in some cases when two DataFrames had the same columns in different orders ([GH28839](#))
- Bug in `DataFrame.replace()` that caused non-numeric replacer's dtype not respected ([GH26632](#))
- Bug in `melt()` where supplying mixed strings and numeric values for `id_vars` or `value_vars` would incorrectly raise a `ValueError` ([GH29718](#))
- Dtypes are now preserved when transposing a DataFrame where each column is the same extension dtype ([GH30091](#))
- Bug in `merge_asof()` merging on a tz-aware `left_index` and `right_on` a tz-aware column ([GH29864](#))
- Improved error message and docstring in `cut()` and `qcut()` when `labels=True` ([GH13318](#))
- Bug in missing `fill_na` parameter to `DataFrame.unstack()` with list of levels ([GH30740](#))

1.9.16 Sparse

- Bug in `SparseDataFrame` arithmetic operations incorrectly casting inputs to float ([GH28107](#))
- Bug in `DataFrame.sparse` returning a Series when there was a column named `sparse` rather than the accessor ([GH30758](#))
- Fixed `operator.xor()` with a boolean-dtype `SparseArray`. Now returns a sparse result, rather than object dtype ([GH31025](#))

1.9.17 ExtensionArray

- Bug in `arrays.PandasArray` when setting a scalar string ([GH28118](#), [GH28150](#)).
- Bug where nullable integers could not be compared to strings ([GH28930](#))
- Bug where `DataFrame` constructor raised `ValueError` with list-like data and `dtype` specified ([GH30280](#))

1.9.18 Other

- Trying to set the `display.precision`, `display.max_rows` or `display.max_columns` using `set_option()` to anything but a `None` or a positive int will raise a `ValueError` ([GH23348](#))
- Using `DataFrame.replace()` with overlapping keys in a nested dictionary will no longer raise, now matching the behavior of a flat dictionary ([GH27660](#))
- `DataFrame.to_csv()` and `Series.to_csv()` now support dicts as `compression` argument with key '`method`' being the compression method and others as additional compression options when the compression method is '`zip`'. ([GH26023](#))
- Bug in `Series.diff()` where a boolean series would incorrectly raise a `TypeError` ([GH17294](#))
- `Series.append()` will no longer raise a `TypeError` when passed a tuple of `Series` ([GH28410](#))
- Fix corrupted error message when calling `pandas.libs._json.encode()` on a 0d array ([GH18878](#))
- Backtick quoting in `DataFrame.query()` and `DataFrame.eval()` can now also be used to use invalid identifiers like names that start with a digit, are python keywords, or are using single character operators. ([GH27017](#))
- Bug in `pd.core.util.hashing.hash_pandas_object` where arrays containing tuples were incorrectly treated as non-hashable ([GH28969](#))

- Bug in DataFrame.append() that raised IndexError when appending with empty list ([GH28769](#))
- Fix AbstractHolidayCalendar to return correct results for years after 2030 (now goes up to 2200) ([GH27790](#))
- Fixed IntegerArray returning inf rather than NaN for operations dividing by 0 ([GH27398](#))
- Fixed pow operations for IntegerArray when the other value is 0 or 1 ([GH29997](#))
- Bug in Series.count() raises if use_inf_as_na is enabled ([GH29478](#))
- Bug in Index where a non-hashable name could be set without raising TypeError ([GH29069](#))
- Bug in DataFrame constructor when passing a 2D ndarray and an extension dtype ([GH12513](#))
- Bug in DataFrame.to_csv() when supplied a series with a dtype="string" and a na_rep, the na_rep was being truncated to 2 characters. ([GH29975](#))
- Bug where DataFrame.itertuples() would incorrectly determine whether or not namedtuples could be used for dataframes of 255 columns ([GH28282](#))
- Handle nested NumPy object arrays in testing.assert_series_equal() for ExtensionArray implementations ([GH30841](#))
- Bug in Index constructor incorrectly allowing 2-dimensional input arrays ([GH13601](#), [GH27125](#))

GETTING STARTED

`{{ header }}`

2.1 Installation

The easiest way to install pandas is to install it as part of the [Anaconda](#) distribution, a cross platform distribution for data analysis and scientific computing. This is the recommended installation method for most users.

Instructions for installing from source, [PyPI](#), [ActivePython](#), various Linux distributions, or a [development version](#) are also provided.

2.1.1 Python version support

Officially Python 3.6.1 and above, 3.7, and 3.8.

2.1.2 Installing pandas

Installing with Anaconda

Installing pandas and the rest of the [NumPy](#) and [SciPy](#) stack can be a little difficult for inexperienced users.

The simplest way to install not only pandas, but Python and the most popular packages that make up the [SciPy](#) stack ([IPython](#), [NumPy](#), [Matplotlib](#), ...) is with [Anaconda](#), a cross-platform (Linux, Mac OS X, Windows) Python distribution for data analytics and scientific computing.

After running the installer, the user will have access to pandas and the rest of the [SciPy](#) stack without needing to install anything else, and without needing to wait for any software to be compiled.

Installation instructions for [Anaconda](#) can be found [here](#).

A full list of the packages available as part of the [Anaconda](#) distribution [can be found here](#).

Another advantage to installing Anaconda is that you don't need admin rights to install it. Anaconda can install in the user's home directory, which makes it trivial to delete Anaconda if you decide (just delete that folder).

Installing with Miniconda

The previous section outlined how to get pandas installed as part of the [Anaconda](#) distribution. However this approach means you will install well over one hundred packages and involves downloading the installer which is a few hundred megabytes in size.

If you want to have more control on which packages, or have a limited internet bandwidth, then installing pandas with [Miniconda](#) may be a better solution.

[Conda](#) is the package manager that the [Anaconda](#) distribution is built upon. It is a package manager that is both cross-platform and language agnostic (it can play a similar role to a pip and virtualenv combination).

[Miniconda](#) allows you to create a minimal self contained Python installation, and then use the [Conda](#) command to install additional packages.

First you will need [Conda](#) to be installed and downloading and running the [Miniconda](#) will do this for you. The installer [can be found here](#)

The next step is to create a new conda environment. A conda environment is like a virtualenv that allows you to specify a specific version of Python and set of libraries. Run the following commands from a terminal window:

```
conda create -n name_of_my_env python
```

This will create a minimal environment with only Python installed in it. To put your self inside this environment run:

```
source activate name_of_my_env
```

On Windows the command is:

```
activate name_of_my_env
```

The final step required is to install pandas. This can be done with the following command:

```
conda install pandas
```

To install a specific pandas version:

```
conda install pandas=0.20.3
```

To install other packages, IPython for example:

```
conda install ipython
```

To install the full [Anaconda](#) distribution:

```
conda install anaconda
```

If you need packages that are available to pip but not conda, then install pip, and then use pip to install those packages:

```
conda install pip  
pip install django
```

Installing from PyPI

pandas can be installed via pip from PyPI.

```
pip install pandas
```

Installing with ActivePython

Installation instructions for ActivePython can be found [here](#). Versions 2.7, 3.5 and 3.6 include pandas.

Installing using your Linux distribution's package manager.

The commands in this table will install pandas for Python 3 from your distribution. To install pandas for Python 2, you may need to use the `python-pandas` package.

Distribution	Status	Download / Repository Link	Install method
Debian	stable	official Debian repository	<code>sudo apt-get install python3-pandas</code>
Debian & Ubuntu	unstable (latest packages)	NeuroDebian	<code>sudo apt-get install python3-pandas</code>
Ubuntu	stable	official Ubuntu repository	<code>sudo apt-get install python3-pandas</code>
OpenSuse	stable	OpenSuse Repository	<code>zypper in python3-pandas</code>
Fedora	stable	official Fedora repository	<code>dnf install python3-pandas</code>
Centos/RHEL	stable	EPEL repository	<code>yum install python3-pandas</code>

However, the packages in the linux package managers are often a few versions behind, so to get the newest version of pandas, it's recommended to install using the `pip` or `conda` methods described above.

Installing from source

See the [contributing guide](#) for complete instructions on building from the git source tree. Further, see [creating a development environment](#) if you wish to create a `pandas` development environment.

2.1.3 Running the test suite

pandas is equipped with an exhaustive set of unit tests, covering about 97% of the code base as of this writing. To run it on your machine to verify that everything is working (and that you have all of the dependencies, soft and hard, installed), make sure you have `pytest` \geq 5.0.1 and `Hypothesis` \geq 3.58, then run:

```
>>> pd.test()
running: pytest --skip-slow --skip-network C:\Users\TP\Anaconda3\envs\py36\lib\site-packages\pandas
=====
 test session starts =====
platform win32 -- Python 3.6.2, pytest-3.6.0, py-1.4.34, pluggy-0.4.0
rootdir: C:\Users\TP\Documents\Python\pandasdev\pandas, ini file: setup.cfg
```

(continues on next page)

(continued from previous page)

```
collected 12145 items / 3 skipped  
.....S.....  
===== 12130 passed, 12 skipped in 368.339 seconds =====
```

2.1.4 Dependencies

Package	Minimum supported version
setuptools	24.2.0
NumPy	1.13.3
python-dateutil	2.6.1
pytz	2017.2

Recommended dependencies

- `numexpr`: for accelerating certain numerical operations. `numexpr` uses multiple cores as well as smart chunking and caching to achieve large speedups. If installed, must be Version 2.6.2 or higher.
- `bottleneck`: for accelerating certain types of nan evaluations. `bottleneck` uses specialized cython routines to achieve large speedups. If installed, must be Version 1.2.1 or higher.

Note: You are highly encouraged to install these libraries, as they provide speed improvements, especially when working with large data sets.

Optional dependencies

Pandas has many optional dependencies that are only used for specific methods. For example, `pandas.read_hdf()` requires the `pytables` package, while `DataFrame.to_markdown()` requires the `tabulate` package. If the optional dependency is not installed, pandas will raise an `ImportError` when the method requiring that dependency is called.

Dependency	Minimum Version	Notes
BeautifulSoup4	4.6.0	HTML parser for <code>read_html</code> (see note)
Jinja2		Conditional formatting with <code>DataFrame.style</code>
PyQt4		Clipboard I/O
PyQt5		Clipboard I/O
PyTables	3.4.2	HDF5-based reading / writing
SQLAlchemy	1.1.4	SQL support for databases other than sqlite
SciPy	0.19.0	Miscellaneous statistical functions
XLSXWriter	0.9.8	Excel writing
blosc		Compression for HDF5
fastparquet	0.3.2	Parquet reading / writing
gcsfs	0.2.2	Google Cloud Storage access
html5lib		HTML parser for <code>read_html</code> (see note)

Continued on next page

Table 1 – continued from previous page

Dependency	Minimum Version	Notes
lxml	3.8.0	HTML parser for <code>read_html</code> (see note)
matplotlib	2.2.2	Visualization
numba	0.46.0	Alternative execution engine for rolling operations
openpyxl	2.5.7	Reading / writing for xlsx files
pandas-gbq	0.8.0	Google Big Query access
psycopg2		PostgreSQL engine for sqlalchemy
pyarrow	0.12.0	Parquet, ORC (requires 0.13.0), and feather reading / writing
pymysql	0.7.11	MySQL engine for sqlalchemy
pyreadstat		SPSS files (.sav) reading
pytables	3.4.2	HDF5 reading / writing
pyxlsb	1.0.6	Reading for xlsb files
qtpy		Clipboard I/O
s3fs	0.3.0	Amazon S3 access
tabulate	0.8.3	Printing in Markdown-friendly format (see tabulate)
xarray	0.8.2	pandas-like API for N-dimensional data
xclip		Clipboard I/O on linux
xlrd	1.1.0	Excel reading
xlwt	1.2.0	Excel writing
xsel		Clipboard I/O on linux
zlib		Compression for HDF5

Optional dependencies for parsing HTML

One of the following combinations of libraries is needed to use the top-level `read_html()` function:

Changed in version 0.23.0.

- BeautifulSoup4 and html5lib
- BeautifulSoup4 and lxml
- BeautifulSoup4 and html5lib and lxml
- Only lxml, although see [HTML Table Parsing](#) for reasons as to why you should probably **not** take this approach.

Warning:

- if you install BeautifulSoup4 you must install either lxml or html5lib or both. `read_html()` will **not** work with *only* BeautifulSoup4 installed.
- You are highly encouraged to read [HTML Table Parsing gotchas](#). It explains issues surrounding the installation and usage of the above three libraries.

{{ header }}

2.2 Package overview

pandas is a [Python](#) package providing fast, flexible, and expressive data structures designed to make working with “relational” or “labeled” data both easy and intuitive. It aims to be the fundamental high-level building block for doing practical, **real world** data analysis in Python. Additionally, it has the broader goal of becoming **the most powerful and flexible open source data analysis / manipulation tool available in any language**. It is already well on its way toward this goal.

pandas is well suited for many different kinds of data:

- Tabular data with heterogeneously-typed columns, as in an SQL table or Excel spreadsheet
- Ordered and unordered (not necessarily fixed-frequency) time series data.
- Arbitrary matrix data (homogeneously typed or heterogeneous) with row and column labels
- Any other form of observational / statistical data sets. The data actually need not be labeled at all to be placed into a pandas data structure

The two primary data structures of pandas, `Series` (1-dimensional) and `DataFrame` (2-dimensional), handle the vast majority of typical use cases in finance, statistics, social science, and many areas of engineering. For R users, `DataFrame` provides everything that R’s `data.frame` provides and much more. pandas is built on top of [NumPy](#) and is intended to integrate well within a scientific computing environment with many other 3rd party libraries.

Here are just a few of the things that pandas does well:

- Easy handling of **missing data** (represented as `NaN`) in floating point as well as non-floating point data
- Size mutability: columns can be **inserted and deleted** from `DataFrame` and higher dimensional objects
- Automatic and explicit **data alignment**: objects can be explicitly aligned to a set of labels, or the user can simply ignore the labels and let `Series`, `DataFrame`, etc. automatically align the data for you in computations
- Powerful, flexible **group by** functionality to perform split-apply-combine operations on data sets, for both aggregating and transforming data
- Make it **easy to convert** ragged, differently-indexed data in other Python and NumPy data structures into `DataFrame` objects
- Intelligent label-based **slicing**, **fancy indexing**, and **subsetting** of large data sets
- Intuitive **merging** and **joining** data sets
- Flexible **reshaping** and pivoting of data sets
- **Hierarchical** labeling of axes (possible to have multiple labels per tick)
- Robust IO tools for loading data from **flat files** (CSV and delimited), Excel files, databases, and saving / loading data from the ultrafast **HDF5 format**
- **Time series**-specific functionality: date range generation and frequency conversion, moving window statistics, date shifting and lagging.

Many of these principles are here to address the shortcomings frequently experienced using other languages / scientific research environments. For data scientists, working with data is typically divided into multiple stages: munging and cleaning data, analyzing / modeling it, then organizing the results of the analysis into a form suitable for plotting or tabular display. pandas is the ideal tool for all of these tasks.

Some other notes

- pandas is **fast**. Many of the low-level algorithmic bits have been extensively tweaked in [Cython](#) code. However, as with anything else generalization usually sacrifices performance. So if you focus on one feature for your application you may be able to create a faster specialized tool.

- pandas is a dependency of `statsmodels`, making it an important part of the statistical computing ecosystem in Python.
- pandas has been used extensively in production in financial applications.

2.2.1 Data structures

Dimensions	Name	Description
1	Series	1D labeled homogeneously-typed array
2	DataFrame	General 2D labeled, size-mutable tabular structure with potentially heterogeneously-typed column

Why more than one data structure?

The best way to think about the pandas data structures is as flexible containers for lower dimensional data. For example, DataFrame is a container for Series, and Series is a container for scalars. We would like to be able to insert and remove objects from these containers in a dictionary-like fashion.

Also, we would like sensible default behaviors for the common API functions which take into account the typical orientation of time series and cross-sectional data sets. When using ndarrays to store 2- and 3-dimensional data, a burden is placed on the user to consider the orientation of the data set when writing functions; axes are considered more or less equivalent (except when C- or Fortran-contiguity matters for performance). In pandas, the axes are intended to lend more semantic meaning to the data; i.e., for a particular data set there is likely to be a “right” way to orient the data. The goal, then, is to reduce the amount of mental effort required to code up data transformations in downstream functions.

For example, with tabular data (DataFrame) it is more semantically helpful to think of the **index** (the rows) and the **columns** rather than axis 0 and axis 1. Iterating through the columns of the DataFrame thus results in more readable code:

```
for col in df.columns:
    series = df[col]
    # do something with series
```

2.2.2 Mutability and copying of data

All pandas data structures are value-mutable (the values they contain can be altered) but not always size-mutable. The length of a Series cannot be changed, but, for example, columns can be inserted into a DataFrame. However, the vast majority of methods produce new objects and leave the input data untouched. In general we like to **favor immutability** where sensible.

2.2.3 Getting support

The first stop for pandas issues and ideas is the [Github Issue Tracker](#). If you have a general question, pandas community experts can answer through [Stack Overflow](#).

2.2.4 Community

pandas is actively supported today by a community of like-minded individuals around the world who contribute their valuable time and energy to help make open source pandas possible. Thanks to [all of our contributors](#).

If you're interested in contributing, please visit the [contributing guide](#).

pandas is a [NumFOCUS](#) sponsored project. This will help ensure the success of development of pandas as a world-class open-source project, and makes it possible to [donate](#) to the project.

2.2.5 Project governance

The governance process that pandas project has used informally since its inception in 2008 is formalized in [Project Governance documents](#). The documents clarify how decisions are made and how the various elements of our community interact, including the relationship between open source collaborative development and work that may be funded by for-profit or non-profit entities.

Wes McKinney is the Benevolent Dictator for Life (BDFL).

2.2.6 Development team

The list of the Core Team members and more detailed information can be found on the [people's](#) page of the governance repo.

2.2.7 Institutional partners

The information about current institutional partners can be found on [pandas website](#) page.

2.2.8 License

2.3 10 minutes to pandas

This is a short introduction to pandas, geared mainly for new users. You can see more complex recipes in the *Cookbook*. Customarily, we import as follows:

In [1]: `import numpy as np`**In [2]:** `import pandas as pd`

2.3.1 Object creation

See the *Data Structure Intro* section.

Creating a Series by passing a list of values, letting pandas create a default integer index:

In [3]: `s = pd.Series([1, 3, 5, np.nan, 6, 8])`**In [4]:** `s`**Out[4]:**

0	1.0
1	3.0
2	5.0
3	NaN
4	6.0
5	8.0
	dtype: float64

Creating a DataFrame by passing a NumPy array, with a datetime index and labeled columns:

In [5]: `dates = pd.date_range('20130101', periods=6)`**In [6]:** `dates`**Out[6]:**

DatetimeIndex(['2013-01-01', '2013-01-02', '2013-01-03', '2013-01-04', '2013-01-05', '2013-01-06'], dtype='datetime64[ns]', freq='D')

In [7]: `df = pd.DataFrame(np.random.randn(6, 4), index=dates, columns=list('ABCD'))`**In [8]:** `df`**Out[8]:**

	A	B	C	D
0	0.10	0.11	0.12	0.13
1	0.14	0.15	0.16	0.17
2	0.18	0.19	0.20	0.21
3	0.22	0.23	0.24	0.25
4	0.26	0.27	0.28	0.29
5	0.30	0.31	0.32	0.33

(continues on next page)

2013-01-03  0.238314 -1.947552  0.624183  1.643853
2013-01-04  0.070457  0.784813  1.274369 -1.163357
2013-01-05  0.212666 -0.307283 -0.298244  0.774156
2013-01-06  1.331547  0.815509  0.333573 -0.675210
```

Creating a DataFrame by passing a dict of objects that can be converted to series-like.

```
In [9]: df2 = pd.DataFrame({'A': 1.,
...:                     'B': pd.Timestamp('20130102'),
...:                     'C': pd.Series(1, index=list(range(4)), dtype='float32'),
...:                     'D': np.array([3] * 4, dtype='int32'),
...:                     'E': pd.Categorical(["test", "train", "test", "train"]),
...:                     'F': 'foo'})
```

```
In [10]: df2
Out[10]:
      A          B    C   D      E     F
0  1.0 2013-01-02  1.0  3  test  foo
1  1.0 2013-01-02  1.0  3  train  foo
2  1.0 2013-01-02  1.0  3  test  foo
3  1.0 2013-01-02  1.0  3  train  foo
```

The columns of the resulting DataFrame have different *dtypes*.

```
In [11]: df2.dtypes
Out[11]:
A          float64
B    datetime64[ns]
C          float32
D          int32
E        category
F          object
dtype: object
```

If you're using IPython, tab completion for column names (as well as public attributes) is automatically enabled. Here's a subset of the attributes that will be completed:

```
In [12]: df2.<TAB> # noqa: E225, E999
df2.A          df2.bool
df2.abs        df2.boxplot
df2.add        df2.C
df2.add_prefix df2.clip
df2.add_suffix df2.clip_lower
df2.align      df2.clip_upper
df2.all        df2.columns
df2.any        df2.combine
df2.append    df2.combine_first
df2.apply      df2.consolidate
df2.applymap
df2.D
```

As you can see, the columns A, B, C, and D are automatically tab completed. E is there as well; the rest of the attributes have been truncated for brevity.

2.3.2 Viewing data

See the [Basics section](#).

Here is how to view the top and bottom rows of the frame:

```
In [13]: df.head()
Out[13]:
          A         B         C         D
2013-01-01 -0.556485 -0.069963  0.053509  0.700984
2013-01-02  0.012835 -0.591444 -0.916947 -0.633578
2013-01-03  0.238314 -1.947552  0.624183  1.643853
2013-01-04  0.070457  0.784813  1.274369 -1.163357
2013-01-05  0.212666 -0.307283 -0.298244  0.774156
```

```
In [14]: df.tail(3)
Out[14]:
          A         B         C         D
2013-01-04  0.070457  0.784813  1.274369 -1.163357
2013-01-05  0.212666 -0.307283 -0.298244  0.774156
2013-01-06  1.331547  0.815509  0.333573 -0.675210
```

Display the index, columns:

```
In [15]: df.index
Out[15]:
DatetimeIndex(['2013-01-01', '2013-01-02', '2013-01-03', '2013-01-04',
               '2013-01-05', '2013-01-06'],
              dtype='datetime64[ns]', freq='D')

In [16]: df.columns
Out[16]: Index(['A', 'B', 'C', 'D'], dtype='object')
```

`DataFrame.to_numpy()` gives a NumPy representation of the underlying data. Note that this can be an expensive operation when your DataFrame has columns with different data types, which comes down to a fundamental difference between pandas and NumPy: **NumPy arrays have one dtype for the entire array, while pandas DataFrames have one dtype per column**. When you call `DataFrame.to_numpy()`, pandas will find the NumPy dtype that can hold *all* of the dtypes in the DataFrame. This may end up being `object`, which requires casting every value to a Python object.

For `df`, our DataFrame of all floating-point values, `DataFrame.to_numpy()` is fast and doesn't require copying data.

```
In [17]: df.to_numpy()
Out[17]:
array([[-0.55648497, -0.06996293,  0.05350907,  0.70098388],
       [ 0.01283519, -0.5914437 , -0.91694703, -0.63357792],
       [ 0.23831391, -1.94755228,  0.62418336,  1.64385333],
       [ 0.0704573 ,  0.78481263,  1.27436921, -1.16335694],
       [ 0.21266561, -0.30728284, -0.29824397,  0.77415599],
       [ 1.33154748,  0.81550931,  0.33357263, -0.67521047]])
```

For `df2`, the DataFrame with multiple dtypes, `DataFrame.to_numpy()` is relatively expensive.

```
In [18]: df2.to_numpy()
Out[18]:
array([[1.0, Timestamp('2013-01-02 00:00:00'), 1.0, 3, 'test', 'foo'],
       [1.0, Timestamp('2013-01-02 00:00:00'), 1.0, 3, 'train', 'foo']])
```

(continues on next page)

(continued from previous page)

```
[1.0, Timestamp('2013-01-02 00:00:00'), 1.0, 3, 'test', 'foo'],
[1.0, Timestamp('2013-01-02 00:00:00'), 1.0, 3, 'train', 'foo']],
dtype=object)
```

Note: DataFrame.to_numpy() does *not* include the index or column labels in the output.

describe() shows a quick statistic summary of your data:

```
In [19]: df.describe()
Out[19]:
          A            B            C            D
count  6.000000  6.000000  6.000000  6.000000
mean   0.218222 -0.219320  0.178407  0.107808
std    0.617109  1.023178  0.757169  1.089398
min   -0.556485 -1.947552 -0.916947 -1.163357
25%    0.027241 -0.520403 -0.210306 -0.664802
50%    0.141561 -0.188623  0.193541  0.033703
75%    0.231902  0.571119  0.551531  0.755863
max    1.331547  0.815509  1.274369  1.643853
```

Transposing your data:

```
In [20]: df.T
Out[20]:
           2013-01-01  2013-01-02  2013-01-03  2013-01-04  2013-01-05  2013-01-06
A     -0.556485    0.012835    0.238314    0.070457    0.212666   1.331547
B     -0.069963   -0.591444   -1.947552    0.784813   -0.307283   0.815509
C      0.053509   -0.916947    0.624183    1.274369   -0.298244   0.333573
D      0.700984   -0.633578    1.643853   -1.163357    0.774156   -0.675210
```

Sorting by an axis:

```
In [21]: df.sort_index(axis=1, ascending=False)
Out[21]:
           D            C            B            A
2013-01-01  0.700984  0.053509 -0.069963 -0.556485
2013-01-02  -0.633578 -0.916947 -0.591444  0.012835
2013-01-03   1.643853  0.624183 -1.947552  0.238314
2013-01-04  -1.163357  1.274369  0.784813  0.070457
2013-01-05   0.774156 -0.298244 -0.307283  0.212666
2013-01-06  -0.675210  0.333573  0.815509  1.331547
```

Sorting by values:

```
In [22]: df.sort_values(by='B')
Out[22]:
          A            B            C            D
2013-01-03  0.238314 -1.947552  0.624183  1.643853
2013-01-02  0.012835 -0.591444 -0.916947 -0.633578
2013-01-05  0.212666 -0.307283 -0.298244  0.774156
2013-01-01 -0.556485 -0.069963  0.053509  0.700984
2013-01-04  0.070457  0.784813  1.274369 -1.163357
2013-01-06  1.331547  0.815509  0.333573 -0.675210
```

2.3.3 Selection

Note: While standard Python / Numpy expressions for selecting and setting are intuitive and come in handy for interactive work, for production code, we recommend the optimized pandas data access methods, `.at`, `.iat`, `.loc` and `.iloc`.

See the indexing documentation [Indexing and Selecting Data](#) and [MultiIndex / Advanced Indexing](#).

Getting

Selecting a single column, which yields a `Series`, equivalent to `df.A`:

```
In [23]: df['A']
Out[23]:
2013-01-01    -0.556485
2013-01-02     0.012835
2013-01-03     0.238314
2013-01-04     0.070457
2013-01-05     0.212666
2013-01-06     1.331547
Freq: D, Name: A, dtype: float64
```

Selecting via `[]`, which slices the rows.

```
In [24]: df[0:3]
Out[24]:
          A         B         C         D
2013-01-01 -0.556485 -0.069963  0.053509  0.700984
2013-01-02   0.012835 -0.591444 -0.916947 -0.633578
2013-01-03   0.238314 -1.947552  0.624183  1.643853

In [25]: df['20130102':'20130104']
Out[25]:
          A         B         C         D
2013-01-02   0.012835 -0.591444 -0.916947 -0.633578
2013-01-03   0.238314 -1.947552  0.624183  1.643853
2013-01-04   0.070457   0.784813  1.274369 -1.163357
```

Selection by label

See more in [Selection by Label](#).

For getting a cross section using a label:

```
In [26]: df.loc[dates[0]]
Out[26]:
A    -0.556485
B    -0.069963
C     0.053509
D     0.700984
Name: 2013-01-01 00:00:00, dtype: float64
```

Selecting on a multi-axis by label:

```
In [27]: df.loc[:, ['A', 'B']]
Out[27]:
          A          B
2013-01-01 -0.556485 -0.069963
2013-01-02  0.012835 -0.591444
2013-01-03  0.238314 -1.947552
2013-01-04  0.070457  0.784813
2013-01-05  0.212666 -0.307283
2013-01-06  1.331547  0.815509
```

Showing label slicing, both endpoints are *included*:

```
In [28]: df.loc['20130102':'20130104', ['A', 'B']]
Out[28]:
          A          B
2013-01-02  0.012835 -0.591444
2013-01-03  0.238314 -1.947552
2013-01-04  0.070457  0.784813
```

Reduction in the dimensions of the returned object:

```
In [29]: df.loc['20130102', ['A', 'B']]
Out[29]:
A    0.012835
B   -0.591444
Name: 2013-01-02 00:00:00, dtype: float64
```

For getting a scalar value:

```
In [30]: df.loc[dates[0], 'A']
Out[30]: -0.5564849735999797
```

For getting fast access to a scalar (equivalent to the prior method):

```
In [31]: df.at[dates[0], 'A']
Out[31]: -0.5564849735999797
```

Selection by position

See more in [Selection by Position](#).

Select via the position of the passed integers:

```
In [32]: df.iloc[3]
Out[32]:
A    0.070457
B    0.784813
C    1.274369
D   -1.163357
Name: 2013-01-04 00:00:00, dtype: float64
```

By integer slices, acting similar to numpy/python:

```
In [33]: df.iloc[3:5, 0:2]
Out[33]:
          A          B
```

(continues on next page)

(continued from previous page)

```
2013-01-04  0.070457  0.784813
2013-01-05  0.212666 -0.307283
```

By lists of integer position locations, similar to the numpy/python style:

```
In [34]: df.iloc[[1, 2, 4], [0, 2]]
Out[34]:
          A            C
2013-01-02  0.012835 -0.916947
2013-01-03  0.238314  0.624183
2013-01-05  0.212666 -0.298244
```

For slicing rows explicitly:

```
In [35]: df.iloc[1:3, :]
Out[35]:
          A            B            C            D
2013-01-02  0.012835 -0.591444 -0.916947 -0.633578
2013-01-03  0.238314 -1.947552  0.624183  1.643853
```

For slicing columns explicitly:

```
In [36]: df.iloc[:, 1:3]
Out[36]:
          B            C
2013-01-01 -0.069963  0.053509
2013-01-02 -0.591444 -0.916947
2013-01-03 -1.947552  0.624183
2013-01-04  0.784813  1.274369
2013-01-05 -0.307283 -0.298244
2013-01-06  0.815509  0.333573
```

For getting a value explicitly:

```
In [37]: df.iat[1, 1]
Out[37]: -0.5914436971090123
```

For getting fast access to a scalar (equivalent to the prior method):

```
In [38]: df.iat[1, 1]
Out[38]: -0.5914436971090123
```

Boolean indexing

Using a single column's values to select data.

```
In [39]: df[df['A'] > 0]
Out[39]:
          A            B            C            D
2013-01-02  0.012835 -0.591444 -0.916947 -0.633578
2013-01-03  0.238314 -1.947552  0.624183  1.643853
2013-01-04  0.070457  0.784813  1.274369 -1.163357
2013-01-05  0.212666 -0.307283 -0.298244  0.774156
2013-01-06  1.331547  0.815509  0.333573 -0.675210
```

Selecting values from a DataFrame where a boolean condition is met.

```
In [40]: df[df > 0]
Out[40]:
          A         B         C         D
2013-01-01    NaN      NaN  0.053509  0.700984
2013-01-02  0.012835      NaN      NaN      NaN
2013-01-03  0.238314      NaN  0.624183  1.643853
2013-01-04  0.070457  0.784813  1.274369      NaN
2013-01-05  0.212666      NaN      NaN  0.774156
2013-01-06  1.331547  0.815509  0.333573      NaN
```

Using the `isin()` method for filtering:

```
In [41]: df2 = df.copy()

In [42]: df2['E'] = ['one', 'one', 'two', 'three', 'four', 'three']

In [43]: df2
Out[43]:
          A         B         C         D         E
2013-01-01 -0.556485 -0.069963  0.053509  0.700984    one
2013-01-02  0.012835 -0.591444 -0.916947 -0.633578    one
2013-01-03  0.238314 -1.947552  0.624183  1.643853    two
2013-01-04  0.070457  0.784813  1.274369 -1.163357   three
2013-01-05  0.212666 -0.307283 -0.298244  0.774156    four
2013-01-06  1.331547  0.815509  0.333573 -0.675210   three

In [44]: df2[df2['E'].isin(['two', 'four'])]
Out[44]:
          A         B         C         D         E
2013-01-03  0.238314 -1.947552  0.624183  1.643853    two
2013-01-05  0.212666 -0.307283 -0.298244  0.774156    four
```

Setting

Setting a new column automatically aligns the data by the indexes.

```
In [45]: s1 = pd.Series([1, 2, 3, 4, 5, 6], index=pd.date_range('20130102', periods=6))

In [46]: s1
Out[46]:
2013-01-02    1
2013-01-03    2
2013-01-04    3
2013-01-05    4
2013-01-06    5
2013-01-07    6
Freq: D, dtype: int64

In [47]: df['F'] = s1
```

Setting values by label:

```
In [48]: df.at[dates[0], 'A'] = 0
```

Setting values by position:

```
In [49]: df.iat[0, 1] = 0
```

Setting by assigning with a NumPy array:

```
In [50]: df.loc[:, 'D'] = np.array([5] * len(df))
```

The result of the prior setting operations.

```
In [51]: df
Out[51]:
          A         B         C   D   F
2013-01-01  0.000000  0.000000  0.053509  5  NaN
2013-01-02  0.012835 -0.591444 -0.916947  5  1.0
2013-01-03  0.238314 -1.947552  0.624183  5  2.0
2013-01-04  0.070457  0.784813  1.274369  5  3.0
2013-01-05  0.212666 -0.307283 -0.298244  5  4.0
2013-01-06  1.331547  0.815509  0.333573  5  5.0
```

A where operation with setting.

```
In [52]: df2 = df.copy()
```

```
In [53]: df2[df2 > 0] = -df2
```

```
In [54]: df2
Out[54]:
          A         B         C   D   F
2013-01-01  0.000000  0.000000 -0.053509 -5  NaN
2013-01-02 -0.012835 -0.591444 -0.916947 -5 -1.0
2013-01-03 -0.238314 -1.947552 -0.624183 -5 -2.0
2013-01-04 -0.070457 -0.784813 -1.274369 -5 -3.0
2013-01-05 -0.212666 -0.307283 -0.298244 -5 -4.0
2013-01-06 -1.331547 -0.815509 -0.333573 -5 -5.0
```

2.3.4 Missing data

pandas primarily uses the value `np.nan` to represent missing data. It is by default not included in computations. See the [Missing Data section](#).

Reindexing allows you to change/add/delete the index on a specified axis. This returns a copy of the data.

```
In [55]: df1 = df.reindex(index=dates[0:4], columns=list(df.columns) + ['E'])
```

```
In [56]: df1.loc[dates[0]:dates[1], 'E'] = 1
```

```
In [57]: df1
Out[57]:
          A         B         C   D   F       E
2013-01-01  0.000000  0.000000  0.053509  5  NaN  1.0
2013-01-02  0.012835 -0.591444 -0.916947  5  1.0  1.0
2013-01-03  0.238314 -1.947552  0.624183  5  2.0  NaN
2013-01-04  0.070457  0.784813  1.274369  5  3.0  NaN
```

To drop any rows that have missing data.

```
In [58]: df1.dropna(how='any')
Out[58]:
          A         B         C   D   F   E
2013-01-02  0.012835 -0.591444 -0.916947  5  1.0  1.0
```

Filling missing data.

```
In [59]: df1.fillna(value=5)
Out[59]:
          A         B         C   D   F   E
2013-01-01  0.000000  0.000000  0.053509  5  5.0  1.0
2013-01-02  0.012835 -0.591444 -0.916947  5  1.0  1.0
2013-01-03  0.238314 -1.947552  0.624183  5  2.0  5.0
2013-01-04  0.070457  0.784813  1.274369  5  3.0  5.0
```

To get the boolean mask where values are nan.

```
In [60]: pd.isna(df1)
Out[60]:
          A         B         C   D   F   E
2013-01-01  False  False  False  False  True  False
2013-01-02  False  False  False  False  False  False
2013-01-03  False  False  False  False  False  True
2013-01-04  False  False  False  False  False  True
```

2.3.5 Operations

See the [Basic section on Binary Ops](#).

Stats

Operations in general *exclude* missing data.

Performing a descriptive statistic:

```
In [61]: df.mean()
Out[61]:
A    0.310970
B   -0.207659
C    0.178407
D    5.000000
F    3.000000
dtype: float64
```

Same operation on the other axis:

```
In [62]: df.mean(1)
Out[62]:
2013-01-01    1.263377
2013-01-02    0.900889
2013-01-03    1.182989
2013-01-04    2.025928
2013-01-05    1.721428
2013-01-06    2.496126
Freq: D, dtype: float64
```

Operating with objects that have different dimensionality and need alignment. In addition, pandas automatically broadcasts along the specified dimension.

```
In [63]: s = pd.Series([1, 3, 5, np.nan, 6, 8], index=dates).shift(2)
```

```
In [64]: s
```

```
Out[64]:
```

2013-01-01	NaN
2013-01-02	NaN
2013-01-03	1.0
2013-01-04	3.0
2013-01-05	5.0
2013-01-06	NaN

Freq: D, dtype: float64

```
In [65]: df.sub(s, axis='index')
```

```
Out[65]:
```

	A	B	C	D	F
2013-01-01	NaN	NaN	NaN	NaN	NaN
2013-01-02	NaN	NaN	NaN	NaN	NaN
2013-01-03	-0.761686	-2.947552	-0.375817	4.0	1.0
2013-01-04	-2.929543	-2.215187	-1.725631	2.0	0.0
2013-01-05	-4.787334	-5.307283	-5.298244	0.0	-1.0
2013-01-06	NaN	NaN	NaN	NaN	NaN

Apply

Applying functions to the data:

```
In [66]: df.apply(np.cumsum)
```

```
Out[66]:
```

	A	B	C	D	F
2013-01-01	0.000000	0.000000	0.053509	5	NaN
2013-01-02	0.012835	-0.591444	-0.863438	10	1.0
2013-01-03	0.251149	-2.538996	-0.239255	15	3.0
2013-01-04	0.321606	-1.754183	1.035115	20	6.0
2013-01-05	0.534272	-2.061466	0.736871	25	10.0
2013-01-06	1.865819	-1.245957	1.070443	30	15.0

```
In [67]: df.apply(lambda x: x.max() - x.min())
```

```
Out[67]:
```

A	1.331547
B	2.763062
C	2.191316
D	0.000000
F	4.000000

dtype: float64

Histogramming

See more at [Histogramming and Discretization](#).

```
In [68]: s = pd.Series(np.random.randint(0, 7, size=10))
```

```
In [69]: s
```

```
Out[69]:
```

```
0    6  
1    1  
2    6  
3    3  
4    1  
5    0  
6    6  
7    4  
8    1  
9    3  
dtype: int64
```

```
In [70]: s.value_counts()
```

```
Out[70]:
```

```
6    3  
1    3  
3    2  
4    1  
0    1  
dtype: int64
```

String Methods

Series is equipped with a set of string processing methods in the `str` attribute that make it easy to operate on each element of the array, as in the code snippet below. Note that pattern-matching in `str` generally uses regular expressions by default (and in some cases always uses them). See more at [Vectorized String Methods](#).

```
In [71]: s = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca', np.nan, 'CABA', 'dog', 'cat'])
```

```
In [72]: s.str.lower()
```

```
Out[72]:
```

```
0      a  
1      b  
2      c  
3    aaba  
4    baca  
5      NaN  
6    caba  
7      dog  
8      cat  
dtype: object
```

2.3.6 Merge

Concat

pandas provides various facilities for easily combining together Series and DataFrame objects with various kinds of set logic for the indexes and relational algebra functionality in the case of join / merge-type operations.

See the [Merging section](#).

Concatenating pandas objects together with concat ():

```
In [73]: df = pd.DataFrame(np.random.randn(10, 4))

In [74]: df
Out[74]:
          0         1         2         3
0  1.139718  0.407400 -0.280308 -1.965456
1  0.523085  0.930562  1.537963  0.552153
2  0.847993  0.048215 -0.137385  0.308075
3 -0.346445 -0.085748  0.467450 -0.057736
4  0.201837 -1.025966 -1.702140  0.656740
5 -0.161468  1.182280  0.504894 -1.344580
6 -0.414158  3.311431 -0.309496  0.514606
7  0.087383 -0.389553  0.575135  1.968606
8 -0.768259  0.880179  0.055905  0.689976
9 -0.462851 -1.223148  0.847459 -1.419312

# break it into pieces
In [75]: pieces = [df[:3], df[3:7], df[7:]]

In [76]: pd.concat(pieces)
Out[76]:
          0         1         2         3
0  1.139718  0.407400 -0.280308 -1.965456
1  0.523085  0.930562  1.537963  0.552153
2  0.847993  0.048215 -0.137385  0.308075
3 -0.346445 -0.085748  0.467450 -0.057736
4  0.201837 -1.025966 -1.702140  0.656740
5 -0.161468  1.182280  0.504894 -1.344580
6 -0.414158  3.311431 -0.309496  0.514606
7  0.087383 -0.389553  0.575135  1.968606
8 -0.768259  0.880179  0.055905  0.689976
9 -0.462851 -1.223148  0.847459 -1.419312
```

Note: Adding a column to a DataFrame is relatively fast. However, adding a row requires a copy, and may be expensive. We recommend passing a pre-built list of records to the DataFrame constructor instead of building a DataFrame by iteratively appending records to it. See [Appending to dataframe](#) for more.

Join

SQL style merges. See the [Database style joining](#) section.

```
In [77]: left = pd.DataFrame({'key': ['foo', 'foo'], 'lval': [1, 2]})

In [78]: right = pd.DataFrame({'key': ['foo', 'foo'], 'rval': [4, 5]})

In [79]: left
Out[79]:
   key  lval
0  foo     1
1  foo     2

In [80]: right
Out[80]:
   key  rval
0  foo     4
1  foo     5

In [81]: pd.merge(left, right, on='key')
Out[81]:
   key  lval  rval
0  foo     1     4
1  foo     1     5
2  foo     2     4
3  foo     2     5
```

Another example that can be given is:

```
In [82]: left = pd.DataFrame({'key': ['foo', 'bar'], 'lval': [1, 2]})

In [83]: right = pd.DataFrame({'key': ['foo', 'bar'], 'rval': [4, 5]})

In [84]: left
Out[84]:
   key  lval
0  foo     1
1  bar     2

In [85]: right
Out[85]:
   key  rval
0  foo     4
1  bar     5

In [86]: pd.merge(left, right, on='key')
Out[86]:
   key  lval  rval
0  foo     1     4
1  bar     2     5
```

2.3.7 Grouping

By “group by” we are referring to a process involving one or more of the following steps:

- **Splitting** the data into groups based on some criteria
- **Applying** a function to each group independently
- **Combining** the results into a data structure

See the [Grouping section](#).

```
In [87]: df = pd.DataFrame({'A': ['foo', 'bar', 'foo', 'bar',
....:                         'foo', 'bar', 'foo', 'bar'],
....:                         'B': ['one', 'one', 'two', 'three',
....:                               'two', 'two', 'one', 'three'],
....:                         'C': np.random.randn(8),
....:                         'D': np.random.randn(8)})

In [88]: df
Out[88]:
   A      B      C      D
0  foo    one -0.025623 -0.227510
1  bar    one -0.983649  0.043841
2  foo    two  0.805222  0.226631
3  bar   three -0.999064 -1.398911
4  foo    two  0.492443 -0.719576
5  bar    two  0.687140  1.519246
6  foo    one  0.600783 -0.716302
7  foo   three -0.834402  1.074405
```

Grouping and then applying the `sum()` function to the resulting groups.

```
In [89]: df.groupby('A').sum()
Out[89]:
          C      D
A
bar -1.295573  0.164175
foo  1.038423 -0.362351
```

Grouping by multiple columns forms a hierarchical index, and again we can apply the `sum` function.

```
In [90]: df.groupby(['A', 'B']).sum()
Out[90]:
          C      D
A   B
bar one -0.983649  0.043841
     three -0.999064 -1.398911
     two   0.687140  1.519246
foo one  0.575160 -0.943812
     three -0.834402  1.074405
     two   1.297665 -0.492945
```

2.3.8 Reshaping

See the sections on [Hierarchical Indexing](#) and [Reshaping](#).

Stack

```
In [91]: tuples = list(zip(*[['bar', 'bar', 'baz', 'baz',
....:                  'foo', 'foo', 'qux', 'qux'],
....:                  ['one', 'two', 'one', 'two',
....:                  'one', 'two', 'one', 'two']]))

In [92]: index = pd.MultiIndex.from_tuples(tuples, names=['first', 'second'])

In [93]: df = pd.DataFrame(np.random.randn(8, 2), index=index, columns=['A', 'B'])

In [94]: df2 = df[:4]

In [95]: df2
Out[95]:
          A          B
first second
bar   one    -2.014277 -0.529977
      two     0.603758 -1.040120
baz   one    -1.414819 -0.649421
      two     0.055989  0.222561
```

The `stack()` method “compresses” a level in the DataFrame’s columns.

```
In [96]: stacked = df2.stack()

In [97]: stacked
Out[97]:
          first second
bar   one      A    -2.014277
                  B    -0.529977
              two      A     0.603758
                  B    -1.040120
baz   one      A    -1.414819
                  B    -0.649421
              two      A     0.055989
                  B    0.222561
dtype: float64
```

With a “stacked” DataFrame or Series (having a MultiIndex as the `index`), the inverse operation of `stack()` is `unstack()`, which by default unstacks the **last level**:

```
In [98]: stacked.unstack()
Out[98]:
          A          B
first second
bar   one    -2.014277 -0.529977
      two     0.603758 -1.040120
baz   one    -1.414819 -0.649421
      two     0.055989  0.222561
```

(continues on next page)

(continued from previous page)

In [99]: stacked.unstack(1)**Out[99]:**

	second	one	two
first	A	-2.014277	0.603758
	B	-0.529977	-1.040120
baz	A	-1.414819	0.055989
	B	-0.649421	0.222561

In [100]: stacked.unstack(0)**Out[100]:**

	first	bar	baz
second	A	-2.014277	-1.414819
	B	-0.529977	-0.649421
one	A	0.603758	0.055989
	B	-1.040120	0.222561

Pivot tables

See the section on *Pivot Tables*.

In [101]: df = pd.DataFrame({'A': ['one', 'one', 'two', 'three'] * 3,
.....: 'B': ['A', 'B', 'C'] * 4,
.....: 'C': ['foo', 'foo', 'foo', 'bar', 'bar', 'bar'] * 2,
.....: 'D': np.random.randn(12),
.....: 'E': np.random.randn(12)})

.....:**In [102]:** df**Out[102]:**

	A	B	C	D	E
0	one	A	foo	0.582187	-0.833965
1	one	B	foo	2.002342	-1.201311
2	two	C	foo	0.979929	-0.333945
3	three	A	bar	0.714364	-0.030045
4	one	B	bar	-0.714935	-2.275281
5	one	C	bar	0.609779	0.888196
6	two	A	foo	-1.429908	1.130730
7	three	B	foo	-0.061305	-0.108879
8	one	C	foo	0.119049	-1.475254
9	one	A	bar	0.875436	1.451338
10	two	B	bar	1.570983	-0.190849
11	three	C	bar	0.623643	-1.449660

We can produce pivot tables from this data very easily:

In [103]: pd.pivot_table(df, values='D', index=['A', 'B'], columns=['C'])**Out[103]:**

	C	bar	foo
A	B		
one	A	0.875436	0.582187
	B	-0.714935	2.002342
	C	0.609779	0.119049
three	A	0.714364	Nan

(continues on next page)

(continued from previous page)

```
B      NaN -0.061305
C  0.623643      NaN
two   A      NaN -1.429908
      B  1.570983      NaN
      C      NaN  0.979929
```

2.3.9 Time series

pandas has simple, powerful, and efficient functionality for performing resampling operations during frequency conversion (e.g., converting secondly data into 5-minute data). This is extremely common in, but not limited to, financial applications. See the [Time Series section](#).

```
In [104]: rng = pd.date_range('1/1/2012', periods=100, freq='S')

In [105]: ts = pd.Series(np.random.randint(0, 500, len(rng)), index=rng)

In [106]: ts.resample('5Min').sum()
Out[106]:
2012-01-01    24243
Freq: 5T, dtype: int64
```

Time zone representation:

```
In [107]: rng = pd.date_range('3/6/2012 00:00', periods=5, freq='D')

In [108]: ts = pd.Series(np.random.randn(len(rng)), rng)

In [109]: ts
Out[109]:
2012-03-06    0.408759
2012-03-07   -0.344620
2012-03-08   -0.185809
2012-03-09   -0.273804
2012-03-10   -0.307301
Freq: D, dtype: float64

In [110]: ts_utc = ts.tz_localize('UTC')

In [111]: ts_utc
Out[111]:
2012-03-06 00:00:00+00:00    0.408759
2012-03-07 00:00:00+00:00   -0.344620
2012-03-08 00:00:00+00:00   -0.185809
2012-03-09 00:00:00+00:00   -0.273804
2012-03-10 00:00:00+00:00   -0.307301
Freq: D, dtype: float64
```

Converting to another time zone:

```
In [112]: ts_utc.tz_convert('US/Eastern')
Out[112]:
2012-03-05 19:00:00-05:00    0.408759
2012-03-06 19:00:00-05:00   -0.344620
2012-03-07 19:00:00-05:00   -0.185809
2012-03-08 19:00:00-05:00   -0.273804
```

(continues on next page)

(continued from previous page)

```
2012-03-09 19:00:00-05:00 -0.307301
Freq: D, dtype: float64
```

Converting between time span representations:

```
In [113]: rng = pd.date_range('1/1/2012', periods=5, freq='M')

In [114]: ts = pd.Series(np.random.randn(len(rng)), index=rng)

In [115]: ts
Out[115]:
2012-01-31    0.039737
2012-02-29    0.454633
2012-03-31   -1.477452
2012-04-30    1.109385
2012-05-31   -1.176385
Freq: M, dtype: float64

In [116]: ps = ts.to_period()

In [117]: ps
Out[117]:
2012-01    0.039737
2012-02    0.454633
2012-03   -1.477452
2012-04    1.109385
2012-05   -1.176385
Freq: M, dtype: float64

In [118]: ps.to_timestamp()
Out[118]:
2012-01-01    0.039737
2012-02-01    0.454633
2012-03-01   -1.477452
2012-04-01    1.109385
2012-05-01   -1.176385
Freq: MS, dtype: float64
```

Converting between period and timestamp enables some convenient arithmetic functions to be used. In the following example, we convert a quarterly frequency with year ending in November to 9am of the end of the month following the quarter end:

```
In [119]: prng = pd.period_range('1990Q1', '2000Q4', freq='Q-NOV')

In [120]: ts = pd.Series(np.random.randn(len(prng)), prng)

In [121]: ts.index = (prng.asfreq('M', 'e') + 1).asfreq('H', 's') + 9

In [122]: ts.head()
Out[122]:
1990-03-01 09:00    0.854937
1990-06-01 09:00    0.892126
1990-09-01 09:00   -1.744295
1990-12-01 09:00   -0.446940
1991-03-01 09:00    0.680001
Freq: H, dtype: float64
```

2.3.10 Categoricals

pandas can include categorical data in a DataFrame. For full docs, see the [categorical introduction](#) and the [API documentation](#).

```
In [123]: df = pd.DataFrame({ "id": [1, 2, 3, 4, 5, 6],  
.....: "raw_grade": ['a', 'b', 'b', 'a', 'a', 'e']}  
.....:
```

Convert the raw grades to a categorical data type.

```
In [124]: df["grade"] = df["raw_grade"].astype("category")
```

```
In [125]: df["grade"]
```

```
Out[125]:
```

```
0    a  
1    b  
2    b  
3    a  
4    a  
5    e  
Name: grade, dtype: category  
Categories (3, object): [a, b, e]
```

Rename the categories to more meaningful names (assigning to Series.cat.categories is inplace!).

```
In [126]: df["grade"].cat.categories = ["very bad", "good", "very good"]
```

Reorder the categories and simultaneously add the missing categories (methods under Series .cat return a new Series by default).

```
In [127]: df["grade"] = df["grade"].cat.set_categories(["very bad", "bad", "medium",  
.....: "good", "very good"])  
.....:
```

```
In [128]: df["grade"]
```

```
Out[128]:
```

```
0    very good  
1      good  
2      good  
3    very good  
4    very good  
5    very bad  
Name: grade, dtype: category  
Categories (5, object): [very bad, bad, medium, good, very good]
```

Sorting is per order in the categories, not lexical order.

```
In [129]: df.sort_values(by="grade")
```

```
Out[129]:
```

	id	raw_grade	grade
5	6	e	very bad
1	2	b	good
2	3	b	good
0	1	a	very good
3	4	a	very good
4	5	a	very good

Grouping by a categorical column also shows empty categories.

```
In [130]: df.groupby("grade").size()
Out[130]:
grade
very bad    1
bad          0
medium        0
good          2
very good   3
dtype: int64
```

2.3.11 Plotting

See the *Plotting* docs.

We use the standard convention for referencing the matplotlib API:

```
In [131]: import matplotlib.pyplot as plt

In [132]: plt.close('all')

In [133]: ts = pd.Series(np.random.randn(1000),
.....:                     index=pd.date_range('1/1/2000', periods=1000))
.....:

In [134]: ts = ts.cumsum()

In [135]: ts.plot()
Out[135]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6db35ee110>
```

On a DataFrame, the `plot()` method is a convenience to plot all of the columns with labels:

```
In [136]: df = pd.DataFrame(np.random.randn(1000, 4), index=ts.index,
.....:                               columns=['A', 'B', 'C', 'D'])
.....:

In [137]: df = df.cumsum()

In [138]: plt.figure()
Out[138]: <Figure size 640x480 with 0 Axes>

In [139]: df.plot()
Out[139]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6da6df8f90>

In [140]: plt.legend(loc='best')
Out[140]: <matplotlib.legend.Legend at 0x7f6da6e01b10>
```

2.3.12 Getting data in/out

CSV

Writing to a csv file.

```
In [141]: df.to_csv('foo.csv')
```

Reading from a csv file.

```
In [142]: pd.read_csv('foo.csv')
Out[142]:
   Unnamed: 0      A      B      C      D
0  2000-01-01  1.395718  0.821253  0.632025 -0.101368
1  2000-01-02  1.861353  0.966201  0.733647  1.104718
2  2000-01-03  2.491511  3.165042  0.497328  0.286494
3  2000-01-04  1.425168  2.645281 -1.277439  1.005861
4  2000-01-05  2.521858  2.585777 -2.523239 -0.182687

```

(continues on next page)

(continued from previous page)

```
999 2002-09-26 -39.932806 55.223067 -32.712639 -2.601911
```

```
[1000 rows x 5 columns]
```

HDF5

Reading and writing to *HDFStores*.

Writing to a HDF5 Store.

```
In [143]: df.to_hdf('foo.h5', 'df')
```

Reading from a HDF5 Store.

```
In [144]: pd.read_hdf('foo.h5', 'df')
```

```
Out[144]:
```

	A	B	C	D
2000-01-01	1.395718	0.821253	0.632025	-0.101368

```
[1000 rows x 5 columns]
```

2.3.13 Gotchas

If you are attempting to perform an operation you might see an exception like:

```
>>> if pd.Series([False, True, False]):
...     print("I was true")
Traceback
...
ValueError: The truth value of an array is ambiguous. Use a.empty, a.any() or a.all().
```

See [Comparisons](#) for an explanation and what to do.

See [Gotchas](#) as well. {{ header }}

2.4 Essential basic functionality

Here we discuss a lot of the essential functionality common to the pandas data structures. Here's how to create some of the objects used in the examples from the previous section:

```
In [1]: index = pd.date_range('1/1/2000', periods=8)

In [2]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])

In [3]: df = pd.DataFrame(np.random.randn(8, 3), index=index,
...                      columns=['A', 'B', 'C'])
...:
```

2.4.1 Head and tail

To view a small sample of a Series or DataFrame object, use the `head()` and `tail()` methods. The default number of elements to display is five, but you may pass a custom number.

```
In [4]: long_series = pd.Series(np.random.randn(1000))

In [5]: long_series.head()
Out[5]:
0    0.832743
1   -0.384162
2   -2.040450
3    0.775269
4   -0.700712
dtype: float64

In [6]: long_series.tail(3)
Out[6]:
997   -1.100661
998    1.108598
```

(continues on next page)

(continued from previous page)

```
999    0.980465
dtype: float64
```

2.4.2 Attributes and underlying data

pandas objects have a number of attributes enabling you to access the metadata

- **shape**: gives the axis dimensions of the object, consistent with ndarray
- **Axis labels**
 - **Series**: *index* (only axis)
 - **DataFrame**: *index* (rows) and *columns*

Note, these attributes can be safely assigned to!

```
In [7]: df[:2]
Out[7]:
          A          B          C
2000-01-01  1.321443 -0.120576  0.307801
2000-01-02  1.489111 -1.462356 -0.866495

In [8]: df.columns = [x.lower() for x in df.columns]

In [9]: df
Out[9]:
          a          b          c
2000-01-01  1.321443 -0.120576  0.307801
2000-01-02  1.489111 -1.462356 -0.866495
2000-01-03 -0.311763 -0.322099  0.861845
2000-01-04 -0.330140 -0.868226 -0.982121
2000-01-05 -1.624801 -1.736413  1.175498
2000-01-06 -0.231495  0.550017 -1.273363
2000-01-07 -0.363498 -0.841036  0.753103
2000-01-08 -0.838931 -0.075913 -0.452052
```

Pandas objects (Index, Series, DataFrame) can be thought of as containers for arrays, which hold the actual data and do the actual computation. For many types, the underlying array is a `numpy.ndarray`. However, pandas and 3rd party libraries may *extend* NumPy's type system to add support for custom arrays (see [dtypes](#)).

To get the actual data inside a `Index` or `Series`, use the `.array` property

```
In [10]: s.array
Out[10]:
<PandasArray>
[      0.694190074756482,      1.4522208119079325,     -0.5818094649879193,
 -0.052645650112693725,      0.7140858201724578]
Length: 5, dtype: float64

In [11]: s.index.array
Out[11]:
<PandasArray>
['a', 'b', 'c', 'd', 'e']
Length: 5, dtype: object
```

`array` will always be an `ExtensionArray`. The exact details of what an `ExtensionArray` is and why pandas uses them is a bit beyond the scope of this introduction. See [dtypes](#) for more.

If you know you need a NumPy array, use `to_numpy()` or `numpy.asarray()`.

```
In [12]: s.to_numpy()
Out[12]: array([ 0.69419007,  1.45222081, -0.58180946, -0.05264565,  0.71408582])

In [13]: np.asarray(s)
Out[13]: array([ 0.69419007,  1.45222081, -0.58180946, -0.05264565,  0.71408582])
```

When the Series or Index is backed by an `ExtensionArray`, `to_numpy()` may involve copying data and coercing values. See [dtypes](#) for more.

`to_numpy()` gives some control over the `dtype` of the resulting `numpy.ndarray`. For example, consider datetimes with timezones. NumPy doesn't have a `dtype` to represent timezone-aware datetimes, so there are two possibly useful representations:

1. An object-`dtype` `numpy.ndarray` with `Timestamp` objects, each with the correct `tz`
2. A `datetime64[ns]`-`dtype` `numpy.ndarray`, where the values have been converted to UTC and the time-zone discarded

Timezones may be preserved with `dtype=object`

```
In [14]: ser = pd.Series(pd.date_range('2000', periods=2, tz="CET"))

In [15]: ser.to_numpy(dtype=object)
Out[15]:
array([Timestamp('2000-01-01 00:00:00+0100', tz='CET', freq='D'),
       Timestamp('2000-01-02 00:00:00+0100', tz='CET', freq='D')],
      dtype=object)
```

Or thrown away with `dtype='datetime64[ns]'`

```
In [16]: ser.to_numpy(dtype="datetime64[ns]")
Out[16]:
array(['1999-12-31T23:00:00.000000000', '2000-01-01T23:00:00.000000000'],
      dtype='datetime64[ns]')
```

Getting the “raw data” inside a DataFrame is possibly a bit more complex. When your DataFrame only has a single data type for all the columns, `DataFrame.to_numpy()` will return the underlying data:

```
In [17]: df.to_numpy()
Out[17]:
array([[ 1.32144302, -0.12057584,  0.30780098],

```

If a DataFrame contains homogeneously-typed data, the ndarray can actually be modified in-place, and the changes will be reflected in the data structure. For heterogeneous data (e.g. some of the DataFrame's columns are not all the same `dtype`), this will not be the case. The `values` attribute itself, unlike the axis labels, cannot be assigned to.

Note: When working with heterogeneous data, the `dtype` of the resulting ndarray will be chosen to accommodate all of the data involved. For example, if strings are involved, the result will be of `object` `dtype`. If there are only floats and integers, the resulting array will be of `float` `dtype`.

In the past, pandas recommended `Series.values` or `DataFrame.values` for extracting the data from a Series or DataFrame. You'll still find references to these in old code bases and online. Going forward, we recommend avoiding `.values` and using `.array` or `.to_numpy()`. `.values` has the following drawbacks:

1. When your Series contains an *extension type*, it's unclear whether `Series.values` returns a NumPy array or the extension array. `Series.array` will always return an *ExtensionArray*, and will never copy data. `Series.to_numpy()` will always return a NumPy array, potentially at the cost of copying / coercing values.
2. When your DataFrame contains a mixture of data types, `DataFrame.values` may involve copying data and coercing values to a common dtype, a relatively expensive operation. `DataFrame.to_numpy()`, being a method, makes it clearer that the returned NumPy array may not be a view on the same data in the DataFrame.

2.4.3 Accelerated operations

pandas has support for accelerating certain types of binary numerical and boolean operations using the `numexpr` library and the `bottleneck` libraries.

These libraries are especially useful when dealing with large data sets, and provide large speedups. `numexpr` uses smart chunking, caching, and multiple cores. `bottleneck` is a set of specialized cython routines that are especially fast when dealing with arrays that have nans.

Here is a sample (using 100 column x 100,000 row DataFrames):

Operation	0.11.0 (ms)	Prior Version (ms)	Ratio to Prior
<code>df1 > df2</code>	13.32	125.35	0.1063
<code>df1 * df2</code>	21.71	36.63	0.5928
<code>df1 + df2</code>	22.04	36.50	0.6039

You are highly encouraged to install both libraries. See the section *Recommended Dependencies* for more installation info.

These are both enabled to be used by default, you can control this by setting the options:

```
pd.set_option('compute.use_bottleneck', False)
pd.set_option('compute.use_numexpr', False)
```

2.4.4 Flexible binary operations

With binary operations between pandas data structures, there are two key points of interest:

- Broadcasting behavior between higher- (e.g. DataFrame) and lower-dimensional (e.g. Series) objects.
- Missing data in computations.

We will demonstrate how to manage these issues independently, though they can be handled simultaneously.

Matching / broadcasting behavior

DataFrame has the methods `add()`, `sub()`, `mul()`, `div()` and related functions `radd()`, `rsub()`, ... for carrying out binary operations. For broadcasting behavior, Series input is of primary interest. Using these functions, you can use to either match on the `index` or `columns` via the `axis` keyword:

```
In [18]: df = pd.DataFrame({
....:     'one': pd.Series(np.random.randn(3), index=['a', 'b', 'c']),
....:     'two': pd.Series(np.random.randn(4), index=['a', 'b', 'c', 'd']),
....:     'three': pd.Series(np.random.randn(3), index=['b', 'c', 'd']))}
....:

In [19]: df
Out[19]:
   one      two      three
a -0.908166 -0.721637      NaN
b  1.528612 -0.889572 -0.173377
c  2.265706  1.397425  0.512667
d      NaN -0.741869 -0.199883

In [20]: row = df.iloc[1]

In [21]: column = df['two']

In [22]: df.sub(row, axis='columns')
Out[22]:
   one      two      three
a -2.436778  0.167935      NaN
b  0.000000  0.000000  0.000000
c  0.737094  2.286998  0.686044
d      NaN  0.147703 -0.026506

In [23]: df.sub(row, axis=1)
Out[23]:
   one      two      three
a -2.436778  0.167935      NaN
b  0.000000  0.000000  0.000000
c  0.737094  2.286998  0.686044
d      NaN  0.147703 -0.026506

In [24]: df.sub(column, axis='index')
Out[24]:
   one      two      three
a -0.186529  0.0      NaN
b  2.418185  0.0  0.716195
c  0.868281  0.0 -0.884758
d      NaN  0.0  0.541986

In [25]: df.sub(column, axis=0)
Out[25]:
   one      two      three
a -0.186529  0.0      NaN
b  2.418185  0.0  0.716195
c  0.868281  0.0 -0.884758
d      NaN  0.0  0.541986
```

Furthermore you can align a level of a MultiIndexed DataFrame with a Series.

```
In [26]: dfmi = df.copy()

In [27]: dfmi.index = pd.MultiIndex.from_tuples([(1, 'a'), (1, 'b'),
.....:                               (1, 'c'), (2, 'a')], names=['first', 'second'])

In [28]: dfmi.sub(column, axis=0, level='second')

Out[28]:
          one      two      three
first second
1      a    -0.186529  0.000000     NaN
      b     2.418185  0.000000  0.716195
      c     0.868281  0.000000 -0.884758
2      a        NaN -0.020232  0.521754
```

Series and Index also support the `divmod()` builtin. This function takes the floor division and modulo operation at the same time returning a two-tuple of the same type as the left hand side. For example:

```
In [29]: s = pd.Series(np.arange(10))
```

```
In [30]: s
```

```
Out[30]:
```

```
0    0
1    1
2    2
3    3
4    4
5    5
6    6
7    7
8    8
9    9
dtype: int64
```

```
In [31]: div, rem = divmod(s, 3)
```

```
In [32]: div
```

```
Out[32]:
```

```
0    0
1    0
2    0
3    1
4    1
5    1
6    2
7    2
8    2
9    3
dtype: int64
```

```
In [33]: rem
```

```
Out[33]:
```

```
0    0
1    1
2    2
3    0
```

(continues on next page)

(continued from previous page)

```
4    1
5    2
6    0
7    1
8    2
9    0
dtype: int64

In [34]: idx = pd.Index(np.arange(10))

In [35]: idx
Out[35]: Int64Index([0, 1, 2, 3, 4, 5, 6, 7, 8, 9], dtype='int64')

In [36]: div, rem = divmod(idx, 3)

In [37]: div
Out[37]: Int64Index([0, 0, 0, 1, 1, 1, 2, 2, 2, 3], dtype='int64')

In [38]: rem
Out[38]: Int64Index([0, 1, 2, 0, 1, 2, 0, 1, 2, 0], dtype='int64')
```

We can also do elementwise `divmod()`:

```
In [39]: div, rem = divmod(s, [2, 2, 3, 3, 4, 4, 5, 5, 6, 6])

In [40]: div
Out[40]:
0    0
1    0
2    0
3    1
4    1
5    1
6    1
7    1
8    1
9    1
dtype: int64

In [41]: rem
Out[41]:
0    0
1    1
2    2
3    0
4    0
5    1
6    1
7    2
8    2
9    3
dtype: int64
```

Missing data / operations with fill values

In Series and DataFrame, the arithmetic functions have the option of inputting a *fill_value*, namely a value to substitute when at most one of the values at a location are missing. For example, when adding two DataFrame objects, you may wish to treat NaN as 0 unless both DataFrames are missing that value, in which case the result will be NaN (you can later replace NaN with some other value using `fillna` if you wish).

```
In [42]: df
Out[42]:
      one      two      three
a -0.908166 -0.721637      NaN
b  1.528612 -0.889572 -0.173377
c  2.265706  1.397425  0.512667
d      NaN -0.741869 -0.199883

In [43]: df2
Out[43]:
      one      two      three
a -0.908166 -0.721637  1.000000
b  1.528612 -0.889572 -0.173377
c  2.265706  1.397425  0.512667
d      NaN -0.741869 -0.199883

In [44]: df + df2
Out[44]:
      one      two      three
a -1.816332 -1.443274      NaN
b  3.057225 -1.779145 -0.346755
c  4.531413  2.794851  1.025334
d      NaN -1.483739 -0.399767

In [45]: df.add(df2, fill_value=0)
Out[45]:
      one      two      three
a -1.816332 -1.443274  1.000000
b  3.057225 -1.779145 -0.346755
c  4.531413  2.794851  1.025334
d      NaN -1.483739 -0.399767
```

Flexible comparisons

Series and DataFrame have the binary comparison methods `eq`, `ne`, `lt`, `gt`, `le`, and `ge` whose behavior is analogous to the binary arithmetic operations described above:

```
In [46]: df.gt(df2)
Out[46]:
      one      two      three
a  False  False  False
b  False  False  False
c  False  False  False
d  False  False  False

In [47]: df2.ne(df)
Out[47]:
      one      two      three
a  False  False   True
```

(continues on next page)

(continued from previous page)

```
b    False  False  False
c    False  False  False
d    True   False  False
```

These operations produce a pandas object of the same type as the left-hand-side input that is of dtype `bool`. These boolean objects can be used in indexing operations, see the section on [Boolean indexing](#).

Boolean reductions

You can apply the reductions: `empty`, `any()`, `all()`, and `bool()` to provide a way to summarize a boolean result.

```
In [48]: (df > 0).all()
```

```
Out[48]:
```

```
one      False
two      False
three    False
dtype: bool
```

```
In [49]: (df > 0).any()
```

```
Out[49]:
```

```
one      True
two      True
three    True
dtype: bool
```

You can reduce to a final boolean value.

```
In [50]: (df > 0).any().any()
```

```
Out[50]: True
```

You can test if a pandas object is empty, via the `empty` property.

```
In [51]: df.empty
```

```
Out[51]: False
```

```
In [52]: pd.DataFrame(columns=list('ABC')).empty
```

```
Out[52]: True
```

To evaluate single-element pandas objects in a boolean context, use the method `bool()`:

```
In [53]: pd.Series([True]).bool()
```

```
Out[53]: True
```

```
In [54]: pd.Series([False]).bool()
```

```
Out[54]: False
```

```
In [55]: pd.DataFrame([[True]]).bool()
```

```
Out[55]: True
```

```
In [56]: pd.DataFrame([[False]]).bool()
```

```
Out[56]: False
```

Warning: You might be tempted to do the following:

```
>>> if df:  
...     pass
```

Or

```
>>> df and df2
```

These will both raise errors, as you are trying to compare multiple values.:

```
ValueError: The truth value of an array is ambiguous. Use a.empty, a.any() or a.  
all().
```

See [gotchas](#) for a more detailed discussion.

Comparing if objects are equivalent

Often you may find that there is more than one way to compute the same result. As a simple example, consider `df + df` and `df * 2`. To test that these two computations produce the same result, given the tools shown above, you might imagine using `(df + df == df * 2).all()`. But in fact, this expression is False:

```
In [57]: df + df == df * 2  
Out[57]:  
one    two    three  
a    True   True   False  
b    True   True    True  
c    True   True    True  
d   False   True    True  
  
In [58]: (df + df == df * 2).all()  
Out[58]:  
one      False  
two      True  
three    False  
dtype: bool
```

Notice that the boolean DataFrame `df + df == df * 2` contains some False values! This is because NaNs do not compare as equals:

```
In [59]: np.nan == np.nan  
Out[59]: False
```

So, NDFrame (such as Series and DataFrames) have an `equals()` method for testing equality, with NaNs in corresponding locations treated as equal.

```
In [60]: (df + df).equals(df * 2)  
Out[60]: True
```

Note that the Series or DataFrame index needs to be in the same order for equality to be True:

```
In [61]: df1 = pd.DataFrame({'col': ['foo', 0, np.nan]})  
  
In [62]: df2 = pd.DataFrame({'col': [np.nan, 0, 'foo']}, index=[2, 1, 0])  
  
In [63]: df1.equals(df2)  
Out[63]: False
```

(continues on next page)

(continued from previous page)

```
In [64]: df1.equals(df2.sort_index())
Out[64]: True
```

Comparing array-like objects

You can conveniently perform element-wise comparisons when comparing a pandas data structure with a scalar value:

```
In [65]: pd.Series(['foo', 'bar', 'baz']) == 'foo'
Out[65]:
0    True
1   False
2   False
dtype: bool

In [66]: pd.Index(['foo', 'bar', 'baz']) == 'foo'
Out[66]: array([ True, False, False])
```

Pandas also handles element-wise comparisons between different array-like objects of the same length:

```
In [67]: pd.Series(['foo', 'bar', 'baz']) == pd.Index(['foo', 'bar', 'qux'])
Out[67]:
0    True
1    True
2   False
dtype: bool

In [68]: pd.Series(['foo', 'bar', 'baz']) == np.array(['foo', 'bar', 'qux'])
Out[68]:
0    True
1    True
2   False
dtype: bool
```

Trying to compare `Index` or `Series` objects of different lengths will raise a `ValueError`:

```
In [55]: pd.Series(['foo', 'bar', 'baz']) == pd.Series(['foo', 'bar'])
ValueError: Series lengths must match to compare

In [56]: pd.Series(['foo', 'bar', 'baz']) == pd.Series(['foo'])
ValueError: Series lengths must match to compare
```

Note that this is different from the NumPy behavior where a comparison can be broadcast:

```
In [69]: np.array([1, 2, 3]) == np.array([2])
Out[69]: array([False,  True, False])
```

or it can return `False` if broadcasting can not be done:

```
In [70]: np.array([1, 2, 3]) == np.array([1, 2])
Out[70]: False
```

Combining overlapping data sets

A problem occasionally arising is the combination of two similar data sets where values in one are preferred over the other. An example would be two data series representing a particular economic indicator where one is considered to be of “higher quality”. However, the lower quality series might extend further back in history or have more complete data coverage. As such, we would like to combine two DataFrame objects where missing values in one DataFrame are conditionally filled with like-labeled values from the other DataFrame. The function implementing this operation is `combine_first()`, which we illustrate:

```
In [71]: df1 = pd.DataFrame({'A': [1., np.nan, 3., 5., np.nan],
....:                      'B': [np.nan, 2., 3., np.nan, 6.]})
....:

In [72]: df2 = pd.DataFrame({'A': [5., 2., 4., np.nan, 3., 7.],
....:                      'B': [np.nan, np.nan, 3., 4., 6., 8.]})
....:

In [73]: df1
Out[73]:
   A    B
0  1.0  NaN
1  NaN  2.0
2  3.0  3.0
3  5.0  NaN
4  NaN  6.0

In [74]: df2
Out[74]:
   A    B
0  5.0  NaN
1  2.0  NaN
2  4.0  3.0
3  NaN  4.0
4  3.0  6.0
5  7.0  8.0

In [75]: df1.combine_first(df2)
Out[75]:
   A    B
0  1.0  NaN
1  2.0  2.0
2  3.0  3.0
3  5.0  4.0
4  3.0  6.0
5  7.0  8.0
```

General DataFrame combine

The `combine_first()` method above calls the more general `DataFrame.combine()`. This method takes another DataFrame and a combiner function, aligns the input DataFrame and then passes the combiner function pairs of Series (i.e., columns whose names are the same).

So, for instance, to reproduce `combine_first()` as above:

```
In [76]: def combiner(x, y):
....:     return np.where(pd.isna(x), y, x)
```

(continues on next page)

(continued from previous page)

....:

2.4.5 Descriptive statistics

There exists a large number of methods for computing descriptive statistics and other related operations on *Series*, *DataFrame*. Most of these are aggregations (hence producing a lower-dimensional result) like `sum()`, `mean()`, and `quantile()`, but some of them, like `cumsum()` and `cumprod()`, produce an object of the same size. Generally speaking, these methods take an `axis` argument, just like `ndarray.{sum, std, ...}`, but the axis can be specified by name or integer:

- **Series**: no axis argument needed
- **DataFrame**: “index” (axis=0, default), “columns” (axis=1)

For example:

```
In [77]: df
Out[77]:
   one      two      three
a -0.908166 -0.721637      NaN
b  1.528612 -0.889572 -0.173377
c  2.265706  1.397425  0.512667
d      NaN -0.741869 -0.199883

In [78]: df.mean(0)
Out[78]:
one      0.962051
two     -0.238913
three    0.046469
dtype: float64

In [79]: df.mean(1)
Out[79]:
a     -0.814901
b      0.155221
c     1.391933
d     -0.470876
dtype: float64
```

All such methods have a `skipna` option signaling whether to exclude missing data (`True` by default):

```
In [80]: df.sum(0, skipna=False)
Out[80]:
one      NaN
two     -0.955653
three    NaN
dtype: float64

In [81]: df.sum(axis=1, skipna=True)
Out[81]:
a     -1.629803
b      0.465663
c     4.175799
d     -0.941753
dtype: float64
```

Combined with the broadcasting / arithmetic behavior, one can describe various statistical procedures, like standardization (rendering data zero mean and standard deviation 1), very concisely:

```
In [82]: ts_stand = (df - df.mean()) / df.std()

In [83]: ts_stand.std()
Out[83]:
one      1.0
two      1.0
three    1.0
dtype: float64

In [84]: xs_stand = df.sub(df.mean(1), axis=0).div(df.std(1), axis=0)

In [85]: xs_stand.std(1)
Out[85]:
a      1.0
b      1.0
c      1.0
d      1.0
dtype: float64
```

Note that methods like `cumsum()` and `cumprod()` preserve the location of NaN values. This is somewhat different from `expanding()` and `rolling()`. For more details please see [this note](#).

```
In [86]: df.cumsum()
Out[86]:
       one      two      three
a -0.908166 -0.721637      NaN
b  0.620446 -1.611209 -0.173377
c  2.886153 -0.213784  0.339290
d      NaN -0.955653  0.139406
```

Here is a quick reference summary table of common functions. Each also takes an optional `level` parameter which applies only if the object has a [hierarchical index](#).

Function	Description
count	Number of non-NA observations
sum	Sum of values
mean	Mean of values
mad	Mean absolute deviation
median	Arithmetic median of values
min	Minimum
max	Maximum
mode	Mode
abs	Absolute Value
prod	Product of values
std	Bessel-corrected sample standard deviation
var	Unbiased variance
sem	Standard error of the mean
skew	Sample skewness (3rd moment)
kurt	Sample kurtosis (4th moment)
quantile	Sample quantile (value at %)
cumsum	Cumulative sum
cumprod	Cumulative product
cummax	Cumulative maximum
cummin	Cumulative minimum

Note that by chance some NumPy methods, like `mean`, `std`, and `sum`, will exclude NAs on Series input by default:

```
In [87]: np.mean(df['one'])
Out[87]: 0.9620509044702331

In [88]: np.mean(df['one'].to_numpy())
Out[88]: nan
```

`Series.nunique()` will return the number of unique non-NA values in a Series:

```
In [89]: series = pd.Series(np.random.randn(500))

In [90]: series[20:500] = np.nan

In [91]: series[10:20] = 5

In [92]: series.nunique()
Out[92]: 11
```

Summarizing data: `describe`

There is a convenient `describe()` function which computes a variety of summary statistics about a Series or the columns of a DataFrame (excluding NAs of course):

```
In [93]: series = pd.Series(np.random.randn(1000))

In [94]: series[::-2] = np.nan

In [95]: series.describe()
Out[95]:
count    500.000000
```

(continues on next page)

(continued from previous page)

```
mean      -0.025831
std       1.019799
min      -3.476675
25%     -0.723403
50%      0.004992
75%      0.665154
max      3.005467
dtype: float64

In [96]: frame = pd.DataFrame(np.random.randn(1000, 5),
....:                         columns=['a', 'b', 'c', 'd', 'e'])
....:

In [97]: frame.iloc[::2] = np.nan

In [98]: frame.describe()
Out[98]:
          a            b            c            d            e
count  500.000000  500.000000  500.000000  500.000000  500.000000
mean   -0.022433   0.007518   0.026107  -0.086363   0.056732
std    0.973255   1.017890   0.994469   1.013999   0.970964
min   -2.647937  -2.631857  -2.903741  -3.364922  -2.632001
25%   -0.710032  -0.658098  -0.587922  -0.770998  -0.576971
50%   -0.034173  -0.031847  0.022913  -0.059536   0.086987
75%    0.681861   0.637230   0.696282   0.609513   0.763632
max    2.795655   3.102982   3.010816   2.553561   3.131640
```

You can select specific percentiles to include in the output:

```
In [99]: series.describe(percentiles=[.05, .25, .75, .95])
Out[99]:
          a
count  500.000000
mean   -0.025831
std    1.019799
min   -3.476675
5%    -1.692621
25%   -0.723403
50%    0.004992
75%    0.665154
95%    1.498579
max    3.005467
dtype: float64
```

By default, the median is always included.

For a non-numerical Series object, `describe()` will give a simple summary of the number of unique values and most frequently occurring values:

```
In [100]: s = pd.Series(['a', 'a', 'b', 'b', 'a', 'a', np.nan, 'c', 'd', 'a'])

In [101]: s.describe()
Out[101]:
          a
count      9
unique      4
top        a
freq       5
dtype: object
```

Note that on a mixed-type DataFrame object, `describe()` will restrict the summary to include only numerical columns or, if none are, only categorical columns:

```
In [102]: frame = pd.DataFrame({'a': ['Yes', 'Yes', 'No', 'No'], 'b': range(4)})

In [103]: frame.describe()
Out[103]:
          b
count    4.000000
mean    1.500000
std     1.290994
min    0.000000
25%   0.750000
50%   1.500000
75%   2.250000
max   3.000000
```

This behavior can be controlled by providing a list of types as `include/exclude` arguments. The special value `all` can also be used:

```
In [104]: frame.describe(include=['object'])
Out[104]:
          a
count    4
unique   2
top     Yes
freq     2

In [105]: frame.describe(include=['number'])
Out[105]:
          b
count    4.000000
mean    1.500000
std     1.290994
min    0.000000
25%   0.750000
50%   1.500000
75%   2.250000
max   3.000000

In [106]: frame.describe(include='all')
Out[106]:
          a      b
count    4  4.000000
unique   2    NaN
top     Yes    NaN
freq     2    NaN
mean    NaN  1.500000
std     NaN  1.290994
min    NaN  0.000000
25%   NaN  0.750000
50%   NaN  1.500000
75%   NaN  2.250000
max    NaN  3.000000
```

That feature relies on `select_dtypes`. Refer to there for details about accepted inputs.

Index of min/max values

The `idxmin()` and `idxmax()` functions on Series and DataFrame compute the index labels with the minimum and maximum corresponding values:

```
In [107]: s1 = pd.Series(np.random.randn(5))

In [108]: s1
Out[108]:
0    0.397365
1    0.013097
2   -0.902884
3    1.629301
4   -1.004764
dtype: float64

In [109]: s1.idxmin(), s1.idxmax()
Out[109]: (4, 3)

In [110]: df1 = pd.DataFrame(np.random.randn(5, 3), columns=['A', 'B', 'C'])

In [111]: df1
Out[111]:
          A         B         C
0  1.187496 -0.870518 -0.957053
1  1.199321 -0.912432  0.766225
2  0.483167  1.054030 -0.609858
3  1.808229 -0.388244 -2.230129
4  0.126468 -1.531781  0.636795

In [112]: df1.idxmin(axis=0)
Out[112]:
A    4
B    4
C    3
dtype: int64

In [113]: df1.idxmax(axis=1)
Out[113]:
0    A
1    A
2    B
3    A
4    C
dtype: object
```

When there are multiple rows (or columns) matching the minimum or maximum value, `idxmin()` and `idxmax()` return the first matching index:

```
In [114]: df3 = pd.DataFrame([2, 1, 1, 3, np.nan], columns=['A'], index=list('edcba'))

In [115]: df3
Out[115]:
      A
e    2.0
d    1.0
c    1.0
b    3.0
```

(continues on next page)

(continued from previous page)

```
a   NaN
In [116]: df3['A'].idxmin()
Out[116]: 'd'
```

Note: `idxmin` and `idxmax` are called `argmin` and `argmax` in NumPy.

Value counts (histogramming) / mode

The `value_counts()` Series method and top-level function computes a histogram of a 1D array of values. It can also be used as a function on regular arrays:

```
In [117]: data = np.random.randint(0, 7, size=50)

In [118]: data
Out[118]:
array([4, 4, 3, 5, 6, 0, 0, 2, 6, 4, 2, 5, 5, 0, 0, 0, 1, 3, 3, 3, 3, 6,
       6, 1, 2, 3, 4, 1, 6, 5, 1, 2, 0, 5, 0, 6, 4, 4, 4, 2, 6, 2, 2, 0,
       1, 0, 0, 5, 3, 5])

In [119]: s = pd.Series(data)

In [120]: s.value_counts()
Out[120]:
0    10
6     7
5     7
4     7
3     7
2     7
1     5
dtype: int64

In [121]: pd.value_counts(data)
Out[121]:
0    10
6     7
5     7
4     7
3     7
2     7
1     5
dtype: int64
```

Similarly, you can get the most frequently occurring value(s) (the mode) of the values in a Series or DataFrame:

```
In [122]: s5 = pd.Series([1, 1, 3, 3, 3, 5, 5, 7, 7, 7])

In [123]: s5.mode()
Out[123]:
0    3
1    7
dtype: int64
```

(continues on next page)

(continued from previous page)

```
In [124]: df5 = pd.DataFrame({ "A": np.random.randint(0, 7, size=50),
.....:                      "B": np.random.randint(-10, 15, size=50) })
.....:

In [125]: df5.mode()
Out[125]:
   A    B
0  5.0 -10
1  NaN    4
```

Discretization and quantiling

Continuous values can be discretized using the `cut()` (bins based on values) and `qcut()` (bins based on sample quantiles) functions:

```
In [126]: arr = np.random.randn(20)

In [127]: factor = pd.cut(arr, 4)

In [128]: factor
Out[128]:
[(-0.719, 0.276], (-1.718, -0.719], (0.276, 1.271], (0.276, 1.271], (-1.718, -0.719],  

..., (-1.718, -0.719], (-1.718, -0.719], (1.271, 2.266], (0.276, 1.271], (-1.718, -  

0.719]]
Length: 20
Categories (4, interval[float64]): [(-1.718, -0.719] < (-0.719, 0.276] < (0.276, 1.  

271] <
                  (1.271, 2.266]]

In [129]: factor = pd.cut(arr, [-5, -1, 0, 1, 5])

In [130]: factor
Out[130]:
[(0, 1], (-1, 0], (1, 5], (0, 1], (-5, -1], ..., (-5, -1], (-5, -1], (1, 5], (0, 1],  

(-5, -1])
Length: 20
Categories (4, interval[int64]): [(-5, -1] < (-1, 0] < (0, 1] < (1, 5)]
```

`qcut()` computes sample quantiles. For example, we could slice up some normally distributed data into equal-size quartiles like so:

```
In [131]: arr = np.random.randn(30)

In [132]: factor = pd.qcut(arr, [0, .25, .5, .75, 1])

In [133]: factor
Out[133]:
[(-0.815, 0.0938], (0.0938, 0.572], (0.572, 1.109], (-0.815, 0.0938], (-0.815, 0.  

0938], ..., (-2.254, -0.815], (0.572, 1.109], (-2.254, -0.815], (0.572, 1.109], (-2.  

254, -0.815])
Length: 30
Categories (4, interval[float64]): [(-2.254, -0.815] < (-0.815, 0.0938] < (0.0938, 0.  

572] <
                  (0.572, 1.109]]
```

(continues on next page)

(continued from previous page)

```
In [134]: pd.value_counts(factor)
Out[134]:
(0.572, 1.109]      8
(-2.254, -0.815]   8
(0.0938, 0.572]    7
(-0.815, 0.0938]   7
dtype: int64
```

We can also pass infinite values to define the bins:

```
In [135]: arr = np.random.randn(20)

In [136]: factor = pd.cut(arr, [-np.inf, 0, np.inf])

In [137]: factor
Out[137]:
[(0.0, inf], (0.0, inf], (0.0, inf], (0.0, inf], (0.0, inf], ..., (0.0, inf], (-inf, 0.0], (0.0, inf], (-inf, 0.0], (0.0, inf]
Length: 20
Categories (2, interval[float64]): [(-inf, 0.0] < (0.0, inf]]
```

2.4.6 Function application

To apply your own or another library's functions to pandas objects, you should be aware of the three methods below. The appropriate method to use depends on whether your function expects to operate on an entire DataFrame or Series, row- or column-wise, or elementwise.

1. *Tablewise Function Application*: pipe()
2. *Row or Column-wise Function Application*: apply()
3. *Aggregation API*: agg() and transform()
4. *Applying Elementwise Functions*: applymap()

Tablewise function application

DataFrames and Series can be passed into functions. However, if the function needs to be called in a chain, consider using the pipe() method.

First some setup:

```
In [138]: def extract_city_name(df):
....:
....:     """
....:     Chicago, IL -> Chicago for city_name column
....:     """
....:     df['city_name'] = df['city_and_code'].str.split(",").str.get(0)
....:     return df
....:

In [139]: def add_country_name(df, country_name=None):
....:
....:     """
....:     Chicago -> Chicago-US for city_name column
....:     """
....:
```

(continues on next page)

(continued from previous page)

```
.....:     col = 'city_name'
.....:     df['city_and_country'] = df[col] + country_name
.....:     return df
.....:

In [140]: df_p = pd.DataFrame({'city_and_code': ['Chicago, IL']})
```

`extract_city_name` and `add_country_name` are functions taking and returning DataFrames.

Now compare the following:

```
In [141]: add_country_name(extract_city_name(df_p), country_name='US')
Out[141]:
   city_and_code city_name city_and_country
0    Chicago, IL      Chicago      ChicagoUS
```

Is equivalent to:

```
In [142]: (df_p.pipe(extract_city_name)
.....:         .pipe(add_country_name, country_name="US"))
.....:
Out[142]:
   city_and_code city_name city_and_country
0    Chicago, IL      Chicago      ChicagoUS
```

Pandas encourages the second style, which is known as method chaining. `pipe` makes it easy to use your own or another library's functions in method chains, alongside pandas' methods.

In the example above, the functions `extract_city_name` and `add_country_name` each expected a DataFrame as the first positional argument. What if the function you wish to apply takes its data as, say, the second argument? In this case, provide `pipe` with a tuple of (`callable`, `data_keyword`). `.pipe` will route the DataFrame to the argument specified in the tuple.

For example, we can fit a regression using statsmodels. Their API expects a formula first and a DataFrame as the second argument, `data`. We pass in the function, keyword pair (`sm.ols`, `'data'`) to `pipe`:

```
In [143]: import statsmodels.formula.api as sm

In [144]: bb = pd.read_csv('data/baseball.csv', index_col='id')

In [145]: (bb.query('h > 0')
.....:     .assign(ln_h=lambda df: np.log(df.h))
.....:     .pipe((sm.ols, 'data'), 'hr ~ ln_h + year + g + C(lg)')
.....:     .fit()
.....:     .summary()
.....: )
.....:
Out[145]:
<class 'statsmodels.iolib.summary.Summary'>
"""
                           OLS Regression Results
=====
Dep. Variable:                  hr        R-squared:     0.685

'''						

The pipe method is inspired by unix pipes and more recently `dplyr` and `magrittr`, which have introduced the popular (`%>%`) (read pipe) operator for `R`. The implementation of `pipe` here is quite clean and feels right at home in python. We encourage you to view the source code of `pipe()`.

Row or column-wise function application

Arbitrary functions can be applied along the axes of a DataFrame using the `apply()` method, which, like the descriptive statistics methods, takes an optional `axis` argument:

```
In [146]: df.apply(np.mean)
Out[146]:
one      0.962051
two     -0.238913
three     0.046469
dtype: float64

In [147]: df.apply(np.mean, axis=1)
Out[147]:
a     -0.814901
b      0.155221
c     1.391933
d     -0.470876
dtype: float64

In [148]: df.apply(lambda x: x.max() - x.min())
Out[148]:
one      3.173872
two     2.286998
three    0.712550
```

(continues on next page)

(continued from previous page)

```
dtype: float64

In [149]: df.apply(np.cumsum)
Out[149]:
      one      two      three
a -0.908166 -0.721637      NaN
b  0.620446 -1.611209 -0.173377
c  2.886153 -0.213784  0.339290
d        NaN -0.955653  0.139406

In [150]: df.apply(np.exp)
Out[150]:
      one      two      three
a  0.403263  0.485956      NaN
b  4.611773  0.410831  0.840820
c  9.637930  4.044773  1.669739
d        NaN  0.476223  0.818826
```

The `apply()` method will also dispatch on a string method name.

```
In [151]: df.apply('mean')
Out[151]:
one          0.962051
two         -0.238913
three        0.046469
dtype: float64

In [152]: df.apply('mean', axis=1)
Out[152]:
a      -0.814901
b      0.155221
c      1.391933
d     -0.470876
dtype: float64
```

The return type of the function passed to `apply()` affects the type of the final output from `DataFrame.apply` for the default behaviour:

- If the applied function returns a Series, the final output is a DataFrame. The columns match the index of the Series returned by the applied function.
 - If the applied function returns any other type, the final output is a Series.

This default behaviour can be overridden using the `result_type`, which accepts three options: `reduce`, `broadcast`, and `expand`. These will determine how list-likes return values expand (or not) to a `DataFrame`.

`apply()` combined with some cleverness can be used to answer many questions about a data set. For example, suppose we wanted to extract the date where the maximum value for each column occurred:

```
In [153]: tsdf = pd.DataFrame(np.random.randn(1000, 3), columns=['A', 'B', 'C'],
.....                           index=pd.date_range('1/1/2000', periods=1000))
.....
```

```
In [154]: tsdf.apply(lambda x: x.idxmax())
Out[154]:
A    2001-04-13
B    2001-08-05
```

(continues on next page)

(continued from previous page)

```
C    2000-02-15
dtype: datetime64[ns]
```

You may also pass additional arguments and keyword arguments to the `apply()` method. For instance, consider the following function you would like to apply:

```
def subtract_and_divide(x, sub, divide=1):
    return (x - sub) / divide
```

You may then apply this function as follows:

```
df.apply(subtract_and_divide, args=(5,), divide=3)
```

Another useful feature is the ability to pass Series methods to carry out some Series operation on each column or row:

```
In [155]: tsdf
Out[155]:
      A          B          C
2000-01-01 -0.225792 -0.266696  0.557863
2000-01-02 -0.052866 -0.792015  1.018327
2000-01-03 -0.433025  0.100072  0.575894
2000-01-04      NaN        NaN        NaN
2000-01-05      NaN        NaN        NaN
2000-01-06      NaN        NaN        NaN
2000-01-07      NaN        NaN        NaN
2000-01-08   0.361818 -0.307602 -1.935875
2000-01-09 -1.186532  1.324166  2.429830
2000-01-10   0.901534  1.076131 -0.325087
```

```
In [156]: tsdf.apply(pd.Series.interpolate)
```

```
Out[156]:
      A          B          C
2000-01-01 -0.225792 -0.266696  0.557863
2000-01-02 -0.052866 -0.792015  1.018327
2000-01-03 -0.433025  0.100072  0.575894
2000-01-04 -0.274056  0.018538  0.073540
2000-01-05 -0.115088 -0.062997 -0.428814
2000-01-06  0.043881 -0.144532 -0.931168
2000-01-07  0.202850 -0.226067 -1.433521
2000-01-08   0.361818 -0.307602 -1.935875
2000-01-09 -1.186532  1.324166  2.429830
2000-01-10   0.901534  1.076131 -0.325087
```

Finally, `apply()` takes an argument `raw` which is `False` by default, which converts each row or column into a Series before applying the function. When set to `True`, the passed function will instead receive an `ndarray` object, which has positive performance implications if you do not need the indexing functionality.

Aggregation API

The aggregation API allows one to express possibly multiple aggregation operations in a single concise way. This API is similar across pandas objects, see [groupby API](#), the [window functions API](#), and the [resample API](#). The entry point for aggregation is `DataFrame.aggregate()`, or the alias `DataFrame.agg()`.

We will use a similar starting frame from above:

```
In [157]: tsdf = pd.DataFrame(np.random.randn(10, 3), columns=['A', 'B', 'C'],
.....:                               index=pd.date_range('1/1/2000', periods=10))
.....:

In [158]: tsdf.iloc[3:7] = np.nan

In [159]: tsdf
Out[159]:
          A         B         C
2000-01-01  0.304743 -0.238472 -0.829271
2000-01-02  1.624093 -0.711620  1.142583
2000-01-03 -1.265290  0.010170  1.126119
2000-01-04      NaN      NaN      NaN
2000-01-05      NaN      NaN      NaN
2000-01-06      NaN      NaN      NaN
2000-01-07      NaN      NaN      NaN
2000-01-08 -0.349232 -0.314961 -0.817867
2000-01-09  0.204586  0.199231  0.520643
2000-01-10  0.674029 -0.995674  0.119631
```

Using a single function is equivalent to `apply()`. You can also pass named methods as strings. These will return a Series of the aggregated output:

```
In [160]: tsdf.agg(np.sum)
Out[160]:
A    1.192930
B   -2.051326
C    1.261837
dtype: float64

In [161]: tsdf.agg('sum')
Out[161]:
A    1.192930
B   -2.051326
C    1.261837
dtype: float64

# these are equivalent to a ``.sum()`` because we are aggregating
# on a single function
In [162]: tsdf.sum()
Out[162]:
A    1.192930
B   -2.051326
C    1.261837
dtype: float64
```

Single aggregations on a Series this will return a scalar value:

```
In [163]: tsdf['A'].agg('sum')
Out[163]: 1.1929299023085984
```

Aggregating with multiple functions

You can pass multiple aggregation arguments as a list. The results of each of the passed functions will be a row in the resulting DataFrame. These are naturally named from the aggregation function.

```
In [164]: tsdf.agg(['sum'])
Out[164]:
      A          B          C
sum  1.19293 -2.051326  1.261837
```

Multiple functions yield multiple rows:

```
In [165]: tsdf.agg(['sum', 'mean'])
Out[165]:
      A          B          C
sum  1.192930 -2.051326  1.261837
mean 0.198822 -0.341888  0.210306
```

On a Series, multiple functions return a Series, indexed by the function names:

```
In [166]: tsdf['A'].agg(['sum', 'mean'])
Out[166]:
sum    1.192930
mean   0.198822
Name: A, dtype: float64
```

Passing a lambda function will yield a <lambda> named row:

```
In [167]: tsdf['A'].agg(['sum', lambda x: x.mean()])
Out[167]:
sum    1.192930
<lambda> 0.198822
Name: A, dtype: float64
```

Passing a named function will yield that name for the row:

```
In [168]: def mymean(x):
.....:     return x.mean()
.....:

In [169]: tsdf['A'].agg(['sum', mymean])
Out[169]:
sum    1.192930
mymean 0.198822
Name: A, dtype: float64
```

Aggregating with a dict

Passing a dictionary of column names to a scalar or a list of scalars, to DataFrame.agg allows you to customize which functions are applied to which columns. Note that the results are not in any particular order, you can use an OrderedDict instead to guarantee ordering.

```
In [170]: tsdf.agg({'A': 'mean', 'B': 'sum'})
Out[170]:
A    0.198822
```

(continues on next page)

(continued from previous page)

```
B    -2.051326  
dtype: float64
```

Passing a list-like will generate a DataFrame output. You will get a matrix-like output of all of the aggregators. The output will consist of all unique functions. Those that are not noted for a particular column will be NaN:

```
In [171]: tsdf.agg({'A': ['mean', 'min'], 'B': 'sum'})  
Out[171]:  
          A            B  
mean   0.198822      NaN  
min   -1.265290      NaN  
sum       NaN -2.051326
```

Mixed dtypes

When presented with mixed dtypes that cannot aggregate, .agg will only take the valid aggregations. This is similar to how groupby .agg works.

```
In [172]: mdf = pd.DataFrame({'A': [1, 2, 3],  
.....:                 'B': [1., 2., 3.],  
.....:                 'C': ['foo', 'bar', 'baz'],  
.....:                 'D': pd.date_range('20130101', periods=3)})  
.....:  
  
In [173]: mdf.dtypes  
Out[173]:  
A           int64  
B           float64  
C          object  
D    datetime64[ns]  
dtype: object
```

```
In [174]: mdf.agg(['min', 'sum'])  
Out[174]:  
          A     B            C            D  
min  1  1.0        bar 2013-01-01  
sum  6  6.0  foobarbaz        NaT
```

Custom describe

With .agg() is it possible to easily create a custom describe function, similar to the built in [describe function](#).

```
In [175]: from functools import partial  
  
In [176]: q_25 = partial(pd.Series.quantile, q=0.25)  
  
In [177]: q_25.__name__ = '25%'  
  
In [178]: q_75 = partial(pd.Series.quantile, q=0.75)  
  
In [179]: q_75.__name__ = '75%'
```

(continues on next page)

(continued from previous page)

```
In [180]: tsdf.agg(['count', 'mean', 'std', 'min', q_25, 'median', q_75, 'max'])
Out[180]:
```

	A	B	C
count	6.000000	6.000000	6.000000
mean	0.198822	-0.341888	0.210306
std	0.970820	0.445491	0.888847
min	-1.265290	-0.995674	-0.829271
25%	-0.210777	-0.612455	-0.583492
median	0.254665	-0.276717	0.320137
75%	0.581707	-0.051990	0.974750
max	1.624093	0.199231	1.142583

Transform API

The `transform()` method returns an object that is indexed the same (same size) as the original. This API allows you to provide *multiple* operations at the same time rather than one-by-one. Its API is quite similar to the `.agg` API.

We create a frame similar to the one used in the above sections.

```
In [181]: tsdf = pd.DataFrame(np.random.randn(10, 3), columns=['A', 'B', 'C'],
.....:                               index=pd.date_range('1/1/2000', periods=10))
.....:
```

```
In [182]: tsdf.iloc[3:7] = np.nan
```

```
In [183]: tsdf
```

```
Out[183]:
```

	A	B	C
2000-01-01	1.066290	1.543933	-0.327860
2000-01-02	0.668878	-0.643772	-1.440173
2000-01-03	0.521016	-1.067236	-0.217194
2000-01-04	NaN	NaN	NaN
2000-01-05	NaN	NaN	NaN
2000-01-06	NaN	NaN	NaN
2000-01-07	NaN	NaN	NaN
2000-01-08	-1.288611	-0.422291	-0.238827
2000-01-09	0.863978	-0.483614	0.865261
2000-01-10	1.461343	-0.992033	0.353320

Transform the entire frame. `.transform()` allows input functions as: a NumPy function, a string function name or a user defined function.

```
In [184]: tsdf.transform(np.abs)
```

```
Out[184]:
```

	A	B	C
2000-01-01	1.066290	1.543933	0.327860
2000-01-02	0.668878	0.643772	1.440173
2000-01-03	0.521016	1.067236	0.217194
2000-01-04	NaN	NaN	NaN
2000-01-05	NaN	NaN	NaN
2000-01-06	NaN	NaN	NaN
2000-01-07	NaN	NaN	NaN
2000-01-08	1.288611	0.422291	0.238827
2000-01-09	0.863978	0.483614	0.865261
2000-01-10	1.461343	0.992033	0.353320

(continues on next page)

(continued from previous page)

```
In [185]: tsdf.transform('abs')
Out[185]:
          A         B         C
2000-01-01  1.066290  1.543933  0.327860
2000-01-02  0.668878  0.643772  1.440173
2000-01-03  0.521016  1.067236  0.217194
2000-01-04      NaN      NaN      NaN
2000-01-05      NaN      NaN      NaN
2000-01-06      NaN      NaN      NaN
2000-01-07      NaN      NaN      NaN
2000-01-08  1.288611  0.422291  0.238827
2000-01-09  0.863978  0.483614  0.865261
2000-01-10  1.461343  0.992033  0.353320

In [186]: tsdf.transform(lambda x: x.abs())
Out[186]:
          A         B         C
2000-01-01  1.066290  1.543933  0.327860
2000-01-02  0.668878  0.643772  1.440173
2000-01-03  0.521016  1.067236  0.217194
2000-01-04      NaN      NaN      NaN
2000-01-05      NaN      NaN      NaN
2000-01-06      NaN      NaN      NaN
2000-01-07      NaN      NaN      NaN
2000-01-08  1.288611  0.422291  0.238827
2000-01-09  0.863978  0.483614  0.865261
2000-01-10  1.461343  0.992033  0.353320
```

Here `transform()` received a single function; this is equivalent to a ufunc application.

```
In [187]: np.abs(tsdf)
Out[187]:
          A         B         C
2000-01-01  1.066290  1.543933  0.327860
2000-01-02  0.668878  0.643772  1.440173
2000-01-03  0.521016  1.067236  0.217194
2000-01-04      NaN      NaN      NaN
2000-01-05      NaN      NaN      NaN
2000-01-06      NaN      NaN      NaN
2000-01-07      NaN      NaN      NaN
2000-01-08  1.288611  0.422291  0.238827
2000-01-09  0.863978  0.483614  0.865261
2000-01-10  1.461343  0.992033  0.353320
```

Passing a single function to `.transform()` with a Series will yield a single Series in return.

```
In [188]: tsdf['A'].transform(np.abs)
Out[188]:
2000-01-01    1.066290
2000-01-02    0.668878
2000-01-03    0.521016
2000-01-04      NaN
2000-01-05      NaN
2000-01-06      NaN
2000-01-07      NaN
2000-01-08    1.288611
```

(continues on next page)

(continued from previous page)

Transform with multiple functions

Passing multiple functions will yield a column MultiIndexed DataFrame. The first level will be the original frame column names; the second level will be the names of the transforming functions.

In [189]:	tsdf.transform([np.abs, lambda x: x + 1])																																																																																	
Out [189]:	<table border="1"> <thead> <tr><th></th><th>A</th><th>B</th><th>C</th></tr> <tr><th></th><th>absolute</th><th><lambda></th><th>absolute</th><th><lambda></th><th>absolute</th><th><lambda></th></tr> </thead> <tbody> <tr><td>2000-01-01</td><td>1.066290</td><td>2.066290</td><td>1.543933</td><td>2.543933</td><td>0.327860</td><td>0.672140</td></tr> <tr><td>2000-01-02</td><td>0.668878</td><td>1.668878</td><td>0.643772</td><td>0.356228</td><td>1.440173</td><td>-0.440173</td></tr> <tr><td>2000-01-03</td><td>0.521016</td><td>1.521016</td><td>1.067236</td><td>-0.067236</td><td>0.217194</td><td>0.782806</td></tr> <tr><td>2000-01-04</td><td>NaN</td><td>NaN</td><td>NaN</td><td>NaN</td><td>NaN</td><td>NaN</td></tr> <tr><td>2000-01-05</td><td>NaN</td><td>NaN</td><td>NaN</td><td>NaN</td><td>NaN</td><td>NaN</td></tr> <tr><td>2000-01-06</td><td>NaN</td><td>NaN</td><td>NaN</td><td>NaN</td><td>NaN</td><td>NaN</td></tr> <tr><td>2000-01-07</td><td>NaN</td><td>NaN</td><td>NaN</td><td>NaN</td><td>NaN</td><td>NaN</td></tr> <tr><td>2000-01-08</td><td>1.288611</td><td>-0.288611</td><td>0.422291</td><td>0.577709</td><td>0.238827</td><td>0.761173</td></tr> <tr><td>2000-01-09</td><td>0.863978</td><td>1.863978</td><td>0.483614</td><td>0.516386</td><td>0.865261</td><td>1.865261</td></tr> <tr><td>2000-01-10</td><td>1.461343</td><td>2.461343</td><td>0.992033</td><td>0.007967</td><td>0.353320</td><td>1.353320</td></tr> </tbody> </table>		A	B	C		absolute	<lambda>	absolute	<lambda>	absolute	<lambda>	2000-01-01	1.066290	2.066290	1.543933	2.543933	0.327860	0.672140	2000-01-02	0.668878	1.668878	0.643772	0.356228	1.440173	-0.440173	2000-01-03	0.521016	1.521016	1.067236	-0.067236	0.217194	0.782806	2000-01-04	NaN	NaN	NaN	NaN	NaN	NaN	2000-01-05	NaN	NaN	NaN	NaN	NaN	NaN	2000-01-06	NaN	NaN	NaN	NaN	NaN	NaN	2000-01-07	NaN	NaN	NaN	NaN	NaN	NaN	2000-01-08	1.288611	-0.288611	0.422291	0.577709	0.238827	0.761173	2000-01-09	0.863978	1.863978	0.483614	0.516386	0.865261	1.865261	2000-01-10	1.461343	2.461343	0.992033	0.007967	0.353320	1.353320

Passing multiple functions to a Series will yield a DataFrame. The resulting column names will be the transforming functions.

In [190]:	tsdf['A'].transform([np.abs, lambda x: x + 1])																																	
Out [190]:	<table border="1"> <thead> <tr><th></th><th>absolute</th><th><lambda></th></tr> </thead> <tbody> <tr><td>2000-01-01</td><td>1.066290</td><td>2.066290</td></tr> <tr><td>2000-01-02</td><td>0.668878</td><td>1.668878</td></tr> <tr><td>2000-01-03</td><td>0.521016</td><td>1.521016</td></tr> <tr><td>2000-01-04</td><td>NaN</td><td>NaN</td></tr> <tr><td>2000-01-05</td><td>NaN</td><td>NaN</td></tr> <tr><td>2000-01-06</td><td>NaN</td><td>NaN</td></tr> <tr><td>2000-01-07</td><td>NaN</td><td>NaN</td></tr> <tr><td>2000-01-08</td><td>1.288611</td><td>-0.288611</td></tr> <tr><td>2000-01-09</td><td>0.863978</td><td>1.863978</td></tr> <tr><td>2000-01-10</td><td>1.461343</td><td>2.461343</td></tr> </tbody> </table>		absolute	<lambda>	2000-01-01	1.066290	2.066290	2000-01-02	0.668878	1.668878	2000-01-03	0.521016	1.521016	2000-01-04	NaN	NaN	2000-01-05	NaN	NaN	2000-01-06	NaN	NaN	2000-01-07	NaN	NaN	2000-01-08	1.288611	-0.288611	2000-01-09	0.863978	1.863978	2000-01-10	1.461343	2.461343

Transforming with a dict

Passing a dict of functions will allow selective transforming per column.

In [191]:	tsdf.transform({'A': np.abs, 'B': lambda x: x + 1})																		
Out [191]:	<table border="1"> <thead> <tr><th></th><th>A</th><th>B</th></tr> </thead> <tbody> <tr><td>2000-01-01</td><td>1.066290</td><td>2.543933</td></tr> <tr><td>2000-01-02</td><td>0.668878</td><td>0.356228</td></tr> <tr><td>2000-01-03</td><td>0.521016</td><td>-0.067236</td></tr> <tr><td>2000-01-04</td><td>NaN</td><td>NaN</td></tr> <tr><td>2000-01-05</td><td>NaN</td><td>NaN</td></tr> </tbody> </table>		A	B	2000-01-01	1.066290	2.543933	2000-01-02	0.668878	0.356228	2000-01-03	0.521016	-0.067236	2000-01-04	NaN	NaN	2000-01-05	NaN	NaN
	A	B																	
2000-01-01	1.066290	2.543933																	
2000-01-02	0.668878	0.356228																	
2000-01-03	0.521016	-0.067236																	
2000-01-04	NaN	NaN																	
2000-01-05	NaN	NaN																	

(continues on next page)

(continued from previous page)

2000-01-06	NaN	NaN
2000-01-07	NaN	NaN
2000-01-08	1.288611	0.577709
2000-01-09	0.863978	0.516386
2000-01-10	1.461343	0.007967

Passing a dict of lists will generate a MultiIndexed DataFrame with these selective transforms.

```
In [192]: tsdf.transform({'A': np.abs, 'B': [lambda x: x + 1, 'sqrt']})  
Out[192]:
```

	A	B
	absolute	<lambda>
2000-01-01	1.066290	2.543933 1.242551
2000-01-02	0.668878	0.356228 NaN
2000-01-03	0.521016	-0.067236 NaN
2000-01-04	NaN	NaN NaN
2000-01-05	NaN	NaN NaN
2000-01-06	NaN	NaN NaN
2000-01-07	NaN	NaN NaN
2000-01-08	1.288611	0.577709 NaN
2000-01-09	0.863978	0.516386 NaN
2000-01-10	1.461343	0.007967 NaN

Applying elementwise functions

Since not all functions can be vectorized (accept NumPy arrays and return another array or value), the methods `applymap()` on DataFrame and analogously `map()` on Series accept any Python function taking a single value and returning a single value. For example:

```
In [193]: df4  
Out[193]:
```

	one	two	three
a	-0.908166	-0.721637	NaN
b	1.528612	-0.889572	-0.173377
c	2.265706	1.397425	0.512667
d	NaN	-0.741869	-0.199883

```
In [194]: def f(x):  
.....:     return len(str(x))  
.....:
```

```
In [195]: df4['one'].map(f)
```

```
Out[195]:
```

a	19
b	18
c	18
d	3

Name: one, dtype: int64

```
In [196]: df4.applymap(f)
```

```
Out[196]:
```

	one	two	three
a	19	19	3
b	18	18	20

(continues on next page)

(continued from previous page)

c	18	18	18
d	3	19	19

`Series.map()` has an additional feature; it can be used to easily “link” or “map” values defined by a secondary series. This is closely related to [merging/joining functionality](#):

```
In [197]: s = pd.Series(['six', 'seven', 'six', 'seven', 'six'],
.....:                 index=['a', 'b', 'c', 'd', 'e'])
.....:

In [198]: t = pd.Series({'six': 6., 'seven': 7.})

In [199]: s
Out[199]:
a      six
b    seven
c      six
d    seven
e      six
dtype: object

In [200]: s.map(t)
Out[200]:
a    6.0
b    7.0
c    6.0
d    7.0
e    6.0
dtype: float64
```

2.4.7 Reindexing and altering labels

`reindex()` is the fundamental data alignment method in pandas. It is used to implement nearly all other features relying on label-alignment functionality. To *reindex* means to conform the data to match a given set of labels along a particular axis. This accomplishes several things:

- Reorders the existing data to match a new set of labels
- Inserts missing value (NA) markers in label locations where no data for that label existed
- If specified, `fill` data for missing labels using logic (highly relevant to working with time series data)

Here is a simple example:

```
In [201]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])

In [202]: s
Out[202]:
a    -0.043164
b   -1.132011
c   -0.254895
d   -0.236171
e    0.430230
dtype: float64

In [203]: s.reindex(['e', 'b', 'f', 'd'])
```

(continues on next page)

(continued from previous page)

```
Out[203]:  
e    0.430230  
b   -1.132011  
f      NaN  
d   -0.236171  
dtype: float64
```

Here, the f label was not contained in the Series and hence appears as NaN in the result.

With a DataFrame, you can simultaneously reindex the index and columns:

```
In [204]: df  
Out[204]:  
     one      two      three  
a -0.908166 -0.721637      NaN  
b  1.528612 -0.889572 -0.173377  
c  2.265706  1.397425  0.512667  
d      NaN -0.741869 -0.199883  
  
In [205]: df.reindex(index=['c', 'f', 'b'], columns=['three', 'two', 'one'])  
Out[205]:  
     three      two      one  
c  0.512667  1.397425  2.265706  
f      NaN      NaN      NaN  
b -0.173377 -0.889572  1.528612
```

You may also use `reindex` with an `axis` keyword:

```
In [206]: df.reindex(['c', 'f', 'b'], axis='index')  
Out[206]:  
     one      two      three  
c  2.265706  1.397425  0.512667  
f      NaN      NaN      NaN  
b  1.528612 -0.889572 -0.173377
```

Note that the Index objects containing the actual axis labels can be **shared** between objects. So if we have a Series and a DataFrame, the following can be done:

```
In [207]: rs = s.reindex(df.index)
```

```
In [208]: rs  
Out[208]:  
a   -0.043164  
b   -1.132011  
c   -0.254895  
d   -0.236171  
dtype: float64
```

```
In [209]: rs.index is df.index
```

```
Out[209]: True
```

This means that the reindexed Series's index is the same Python object as the DataFrame's index.

New in version 0.21.0.

`DataFrame.reindex()` also supports an “axis-style” calling convention, where you specify a single `labels` argument and the `axis` it applies to.

```
In [210]: df.reindex(['c', 'f', 'b'], axis='index')
Out[210]:
      one      two      three
c  2.265706  1.397425  0.512667
f      NaN      NaN      NaN
b  1.528612 -0.889572 -0.173377

In [211]: df.reindex(['three', 'two', 'one'], axis='columns')
Out[211]:
      three      two      one
a      NaN -0.721637 -0.908166
b -0.173377 -0.889572  1.528612
c  0.512667  1.397425  2.265706
d -0.199883 -0.741869      NaN
```

See also:

[MultiIndex / Advanced Indexing](#) is an even more concise way of doing reindexing.

Note: When writing performance-sensitive code, there is a good reason to spend some time becoming a reindexing ninja: **many operations are faster on pre-aligned data**. Adding two unaligned DataFrames internally triggers a reindexing step. For exploratory analysis you will hardly notice the difference (because `reindex` has been heavily optimized), but when CPU cycles matter sprinkling a few explicit `reindex` calls here and there can have an impact.

Reindexing to align with another object

You may wish to take an object and reindex its axes to be labeled the same as another object. While the syntax for this is straightforward albeit verbose, it is a common enough operation that the `reindex_like()` method is available to make this simpler:

```
In [212]: df2
Out[212]:
      one      two
a -0.908166 -0.721637
b  1.528612 -0.889572
c  2.265706  1.397425

In [213]: df3
Out[213]:
      one      two
a -1.870217 -0.650376
b  0.566561 -0.818311
c  1.303655  1.468687

In [214]: df.reindex_like(df2)
Out[214]:
      one      two
a -0.908166 -0.721637
b  1.528612 -0.889572
c  2.265706  1.397425
```

Aligning objects with each other with align

The `align()` method is the fastest way to simultaneously align two objects. It supports a `join` argument (related to *joining and merging*):

- `join='outer'`: take the union of the indexes (default)
- `join='left'`: use the calling object's index
- `join='right'`: use the passed object's index
- `join='inner'`: intersect the indexes

It returns a tuple with both of the reindexed Series:

```
In [215]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])

In [216]: s1 = s[:4]

In [217]: s2 = s[1:]

In [218]: s1.align(s2)
Out[218]:
(a    0.545933
 b    0.044595
 c   -1.534815
 d   -0.074242
 e      NaN
dtype: float64,
a      NaN
b    0.044595
c   -1.534815
d   -0.074242
e    0.627894
dtype: float64)

In [219]: s1.align(s2, join='inner')
Out[219]:
(b    0.044595
 c   -1.534815
 d   -0.074242
dtype: float64,
b    0.044595
c   -1.534815
d   -0.074242
dtype: float64)

In [220]: s1.align(s2, join='left')
Out[220]:
(a    0.545933
 b    0.044595
 c   -1.534815
 d   -0.074242
dtype: float64,
a      NaN
b    0.044595
c   -1.534815
d   -0.074242
dtype: float64)
```

For DataFrames, the join method will be applied to both the index and the columns by default:

```
In [221]: df.align(df2, join='inner')
Out[221]:
(   one      two
a -0.908166 -0.721637
b  1.528612 -0.889572
c  2.265706  1.397425,
   one      two
a -0.908166 -0.721637
b  1.528612 -0.889572
c  2.265706  1.397425)
```

You can also pass an axis option to only align on the specified axis:

```
In [222]: df.align(df2, join='inner', axis=0)
Out[222]:
(   one      two      three
a -0.908166 -0.721637      NaN
b  1.528612 -0.889572 -0.173377
c  2.265706  1.397425  0.512667,
   one      two
a -0.908166 -0.721637
b  1.528612 -0.889572
c  2.265706  1.397425)
```

If you pass a Series to DataFrame.align(), you can choose to align both objects either on the DataFrame's index or columns using the axis argument:

```
In [223]: df.align(df2.iloc[0], axis=1)
Out[223]:
(   one      three      two
a -0.908166      NaN -0.721637
b  1.528612 -0.173377 -0.889572
c  2.265706  0.512667  1.397425
d      NaN -0.199883 -0.741869,
one     -0.908166
three     NaN
two     -0.721637
Name: a, dtype: float64)
```

Filling while reindexing

reindex() takes an optional parameter method which is a filling method chosen from the following table:

Method	Action
pad / ffill	Fill values forward
bfill / backfill	Fill values backward
nearest	Fill from the nearest index value

We illustrate these fill methods on a simple Series:

```
In [224]: rng = pd.date_range('1/3/2000', periods=8)
In [225]: ts = pd.Series(np.random.randn(8), index=rng)
```

(continues on next page)

(continued from previous page)

```
In [226]: ts2 = ts[[0, 3, 6]]
```

```
In [227]: ts
```

```
Out[227]:
```

```

These methods require that the indexes are **ordered** increasing or decreasing.

Note that the same result could have been achieved using `fillna` (except for `method='nearest'`) or `interpolate`:

```
In [233]: ts2.reindex(ts.index).fillna(method='ffill')
Out[233]:
2000-01-03    0.887165
2000-01-04    0.887165
2000-01-05    0.887165
2000-01-06    0.316817
2000-01-07    0.316817
2000-01-08    0.316817
2000-01-09   -0.918970
2000-01-10   -0.918970
Freq: D, dtype: float64
```

`reindex()` will raise a `ValueError` if the index is not monotonically increasing or decreasing. `fillna()` and `interpolate()` will not perform any checks on the order of the index.

Limits on filling while reindexing

The `limit` and `tolerance` arguments provide additional control over filling while reindexing. `Limit` specifies the maximum count of consecutive matches:

```
In [234]: ts2.reindex(ts.index, method='ffill', limit=1)
Out[234]:
2000-01-03    0.887165
2000-01-04    0.887165
2000-01-05      NaN
2000-01-06    0.316817
2000-01-07    0.316817
2000-01-08      NaN
2000-01-09   -0.918970
2000-01-10   -0.918970
Freq: D, dtype: float64
```

In contrast, `tolerance` specifies the maximum distance between the index and indexer values:

```
In [235]: ts2.reindex(ts.index, method='ffill', tolerance='1 day')
Out[235]:
2000-01-03    0.887165
2000-01-04    0.887165
2000-01-05      NaN
```

(continues on next page)

(continued from previous page)

```
2000-01-06    0.316817
2000-01-07    0.316817
2000-01-08      NaN
2000-01-09   -0.918970
2000-01-10   -0.918970
Freq: D, dtype: float64
```

Notice that when used on a DatetimeIndex, TimedeltaIndex or PeriodIndex, tolerance will be coerced into a Timedelta if possible. This allows you to specify tolerance with appropriate strings.

Dropping labels from an axis

A method closely related to `reindex` is the `drop()` function. It removes a set of labels from an axis:

```
In [236]: df
Out[236]:
       one      two      three
a -0.908166 -0.721637      NaN
b  1.528612 -0.889572 -0.173377
c  2.265706  1.397425  0.512667
d      NaN -0.741869 -0.199883

In [237]: df.drop(['a', 'd'], axis=0)
Out[237]:
       one      two      three
b  1.528612 -0.889572 -0.173377
c  2.265706  1.397425  0.512667

In [238]: df.drop(['one'], axis=1)
Out[238]:
      two      three
a -0.721637      NaN
b -0.889572 -0.173377
c  1.397425  0.512667
d -0.741869 -0.199883
```

Note that the following also works, but is a bit less obvious / clean:

```
In [239]: df.reindex(df.index.difference(['a', 'd']))
Out[239]:
       one      two      three
b  1.528612 -0.889572 -0.173377
c  2.265706  1.397425  0.512667
```

Renaming / mapping labels

The `rename()` method allows you to relabel an axis based on some mapping (a dict or Series) or an arbitrary function.

```
In [240]: s
Out[240]:
a    0.545933
b    0.044595
c   -1.534815
d   -0.074242
```

(continues on next page)

(continued from previous page)

```
e    0.627894
dtype: float64

In [241]: s.rename(str.upper)
Out[241]:
A    0.545933
B    0.044595
C   -1.534815
D   -0.074242
E    0.627894
dtype: float64
```

If you pass a function, it must return a value when called with any of the labels (and must produce a set of unique values). A dict or Series can also be used:

```
In [242]: df.rename(columns={'one': 'foo', 'two': 'bar'},
.....           index={'a': 'apple', 'b': 'banana', 'd': 'durian'})
.....
Out[242]:
      foo      bar      three
apple -0.908166 -0.721637      NaN
banana  1.528612 -0.889572 -0.173377
c      2.265706  1.397425  0.512667
durian       NaN -0.741869 -0.199883
```

If the mapping doesn't include a column/index label, it isn't renamed. Note that extra labels in the mapping don't throw an error.

New in version 0.21.0.

DataFrame.rename() also supports an “axis-style” calling convention, where you specify a single mapper and the axis to apply that mapping to.

```
In [243]: df.rename({'one': 'foo', 'two': 'bar'}, axis='columns')
Out[243]:
      foo      bar      three
a -0.908166 -0.721637      NaN
b  1.528612 -0.889572 -0.173377
c  2.265706  1.397425  0.512667
d       NaN -0.741869 -0.199883

In [244]: df.rename({'a': 'apple', 'b': 'banana', 'd': 'durian'}, axis='index')
Out[244]:
      one      two      three
apple -0.908166 -0.721637      NaN
banana  1.528612 -0.889572 -0.173377
c      2.265706  1.397425  0.512667
durian       NaN -0.741869 -0.199883
```

The rename() method also provides an `inplace` named parameter that is by default `False` and copies the underlying data. Pass `inplace=True` to rename the data in place.

Finally, rename() also accepts a scalar or list-like for altering the Series.name attribute.

```
In [245]: s.rename("scalar-name")
Out[245]:
a    0.545933
```

(continues on next page)

(continued from previous page)

```
b    0.044595
c   -1.534815
d   -0.074242
e    0.627894
Name: scalar-name, dtype: float64
```

New in version 0.24.0.

The methods `rename_axis()` and `rename_axis()` allow specific names of a *MultiIndex* to be changed (as opposed to the labels).

```
In [246]: df = pd.DataFrame({'x': [1, 2, 3, 4, 5, 6],
.....:                               'y': [10, 20, 30, 40, 50, 60]},
.....:                               index=pd.MultiIndex.from_product([['a', 'b', 'c'], [1, ↵
2]], names=['let', 'num']))
```

```
In [247]: df
```

```
Out[247]:
      x    y
let num
a   1    1  10
     2    2  20
b   1    3  30
     2    4  40
c   1    5  50
     2    6  60
```

```
In [248]: df.rename_axis(index={'let': 'abc'})
```

```
Out[248]:
      x    y
abc num
a   1    1  10
     2    2  20
b   1    3  30
     2    4  40
c   1    5  50
     2    6  60
```

```
In [249]: df.rename_axis(index=str.upper)
```

```
Out[249]:
      x    y
LET NUM
a   1    1  10
     2    2  20
b   1    3  30
     2    4  40
c   1    5  50
     2    6  60
```

2.4.8 Iteration

The behavior of basic iteration over pandas objects depends on the type. When iterating over a Series, it is regarded as array-like, and basic iteration produces the values. DataFrames follow the dict-like convention of iterating over the “keys” of the objects.

In short, basic iteration (`for i in object`) produces:

- **Series**: values
- **DataFrame**: column labels

Thus, for example, iterating over a DataFrame gives you the column names:

```
In [250]: df = pd.DataFrame({'col1': np.random.randn(3),
.....:                      'col2': np.random.randn(3)}, index=['a', 'b', 'c'])
.....:

In [251]: for col in df:
.....:     print(col)
.....:

col1
col2
```

Pandas objects also have the dict-like `items()` method to iterate over the (key, value) pairs.

To iterate over the rows of a DataFrame, you can use the following methods:

- `iterrows()`: Iterate over the rows of a DataFrame as (index, Series) pairs. This converts the rows to Series objects, which can change the dtypes and has some performance implications.
- `itertuples()`: Iterate over the rows of a DataFrame as namedtuples of the values. This is a lot faster than `iterrows()`, and is in most cases preferable to use to iterate over the values of a DataFrame.

Warning: Iterating through pandas objects is generally **slow**. In many cases, iterating manually over the rows is not needed and can be avoided with one of the following approaches:

- Look for a *vectorized* solution: many operations can be performed using built-in methods or NumPy functions, (boolean) indexing, ...
- When you have a function that cannot work on the full DataFrame/Series at once, it is better to use `apply()` instead of iterating over the values. See the docs on [function application](#).
- If you need to do iterative manipulations on the values but performance is important, consider writing the inner loop with cython or numba. See the [enhancing performance](#) section for some examples of this approach.

Warning: You should **never modify** something you are iterating over. This is not guaranteed to work in all cases. Depending on the data types, the iterator returns a copy and not a view, and writing to it will have no effect!

For example, in the following case setting the value has no effect:

```
In [252]: df = pd.DataFrame({'a': [1, 2, 3], 'b': ['a', 'b', 'c']})

In [253]: for index, row in df.iterrows():
.....:     row['a'] = 10
.....:

In [254]: df
Out[254]:
```

```
a   b  
0   1   a  
1   2   b  
2   3   c
```

items

Consistent with the dict-like interface, `items()` iterates through key-value pairs:

- **Series**: (index, scalar value) pairs
- **DataFrame**: (column, Series) pairs

For example:

```
In [255]: for label, ser in df.items():  
.....:     print(label)  
.....:     print(ser)  
.....:  
a  
0    1  
1    2  
2    3  
Name: a, dtype: int64  
b  
0    a  
1    b  
2    c  
Name: b, dtype: object
```

iterrows

`iterrows()` allows you to iterate through the rows of a DataFrame as Series objects. It returns an iterator yielding each index value along with a Series containing the data in each row:

```
In [256]: for row_index, row in df.iterrows():  
.....:     print(row_index, row, sep='\n')  
.....:  
0  
a    1  
b    a  
Name: 0, dtype: object  
1  
a    2  
b    b  
Name: 1, dtype: object  
2  
a    3  
b    c  
Name: 2, dtype: object
```

Note: Because `iterrows()` returns a Series for each row, it does **not** preserve dtypes across the rows (dtypes are preserved across columns for DataFrames). For example,

```
In [257]: df_orig = pd.DataFrame([[1, 1.5]], columns=['int', 'float'])

In [258]: df_orig.dtypes
Out[258]:
int      int64
float    float64
dtype: object

In [259]: row = next(df_orig.iterrows())[1]

In [260]: row
Out[260]:
int    1.0
float  1.5
Name: 0, dtype: float64
```

All values in `row`, returned as a Series, are now upcasted to floats, also the original integer value in column *x*:

```
In [261]: row['int'].dtype
Out[261]: dtype('float64')

In [262]: df_orig['int'].dtype
Out[262]: dtype('int64')
```

To preserve dtypes while iterating over the rows, it is better to use `itertuples()` which returns namedtuples of the values and which is generally much faster than `iterrows()`.

For instance, a contrived way to transpose the DataFrame would be:

```
In [263]: df2 = pd.DataFrame({'x': [1, 2, 3], 'y': [4, 5, 6]})

In [264]: print(df2)
   x  y
0  1  4
1  2  5
2  3  6

In [265]: print(df2.T)
   0  1  2
x  1  2  3
y  4  5  6

In [266]: df2_t = pd.DataFrame({idx: values for idx, values in df2.iterrows()})

In [267]: print(df2_t)
   0  1  2
x  1  2  3
y  4  5  6
```

itertuples

The `itertuples()` method will return an iterator yielding a namedtuple for each row in the DataFrame. The first element of the tuple will be the row's corresponding index value, while the remaining values are the row values.

For instance:

```
In [268]: for row in df.itertuples():
....:     print(row)
....:
Pandas(Index=0, a=1, b='a')
Pandas(Index=1, a=2, b='b')
Pandas(Index=2, a=3, b='c')
```

This method does not convert the row to a Series object; it merely returns the values inside a namedtuple. Therefore, `itertuples()` preserves the data type of the values and is generally faster as `iterrows()`.

Note: The column names will be renamed to positional names if they are invalid Python identifiers, repeated, or start with an underscore. With a large number of columns (>255), regular tuples are returned.

2.4.9 .dt accessor

Series has an accessor to succinctly return datetime like properties for the *values* of the Series, if it is a datetime/period like Series. This will return a Series, indexed like the existing Series.

```
# datetime
In [269]: s = pd.Series(pd.date_range('20130101 09:10:12', periods=4))

In [270]: s
Out[270]:
0    2013-01-01 09:10:12
1    2013-01-02 09:10:12
2    2013-01-03 09:10:12
3    2013-01-04 09:10:12
dtype: datetime64[ns]

In [271]: s.dt.hour
Out[271]:
0      9
1      9
2      9
3      9
dtype: int64

In [272]: s.dt.second
Out[272]:
0      12
1      12
2      12
3      12
dtype: int64

In [273]: s.dt.day
Out[273]:
0      1
```

(continues on next page)

(continued from previous page)

```
1    2
2    3
3    4
dtype: int64
```

This enables nice expressions like this:

```
In [274]: s[s.dt.day == 2]
Out[274]:
1    2013-01-02 09:10:12
dtype: datetime64[ns]
```

You can easily produce tz aware transformations:

```
In [275]: stz = s.dt.tz_localize('US/Eastern')

In [276]: stz
Out[276]:
0    2013-01-01 09:10:12-05:00
1    2013-01-02 09:10:12-05:00
2    2013-01-03 09:10:12-05:00
3    2013-01-04 09:10:12-05:00
dtype: datetime64[ns, US/Eastern]

In [277]: stz.dt.tz
Out[277]: <DstTzInfo 'US/Eastern' LMT-1 day, 19:04:00 STD>
```

You can also chain these types of operations:

```
In [278]: s.dt.tz_localize('UTC').dt.tz_convert('US/Eastern')
Out[278]:
0    2013-01-01 04:10:12-05:00
1    2013-01-02 04:10:12-05:00
2    2013-01-03 04:10:12-05:00
3    2013-01-04 04:10:12-05:00
dtype: datetime64[ns, US/Eastern]
```

You can also format datetime values as strings with `Series.dt.strftime()` which supports the same format as the standard `strftime()`.

```
# DatetimeIndex
In [279]: s = pd.Series(pd.date_range('20130101', periods=4))

In [280]: s
Out[280]:
0    2013-01-01
1    2013-01-02
2    2013-01-03
3    2013-01-04
dtype: datetime64[ns]

In [281]: s.dt.strftime('%Y/%m/%d')
Out[281]:
0    2013/01/01
1    2013/01/02
2    2013/01/03
```

(continues on next page)

(continued from previous page)

```
3    2013/01/04  
dtype: object
```

```
# PeriodIndex  
In [282]: s = pd.Series(pd.period_range('20130101', periods=4))  
  
In [283]: s  
Out[283]:  
0    2013-01-01  
1    2013-01-02  
2    2013-01-03  
3    2013-01-04  
dtype: period[D]  
  
In [284]: s.dt.strftime('%Y/%m/%d')  
Out[284]:  
0    2013/01/01  
1    2013/01/02  
2    2013/01/03  
3    2013/01/04  
dtype: object
```

The .dt accessor works for period and timedelta dtypes.

```
# period  
In [285]: s = pd.Series(pd.period_range('20130101', periods=4, freq='D'))  
  
In [286]: s  
Out[286]:  
0    2013-01-01  
1    2013-01-02  
2    2013-01-03  
3    2013-01-04  
dtype: period[D]  
  
In [287]: s.dt.year  
Out[287]:  
0    2013  
1    2013  
2    2013  
3    2013  
dtype: int64  
  
In [288]: s.dt.day  
Out[288]:  
0    1  
1    2  
2    3  
3    4  
dtype: int64
```

```
# timedelta  
In [289]: s = pd.Series(pd.timedelta_range('1 day 00:00:05', periods=4, freq='S'))  
  
In [290]: s  
Out[290]:
```

(continues on next page)

(continued from previous page)

```
0    1 days 00:00:05
1    1 days 00:00:06
2    1 days 00:00:07
3    1 days 00:00:08
dtype: timedelta64[ns]
```

In [291]: s.dt.days

Out [291]:

```
0      1  
1      1  
2      1  
3      1  
dtype: int64
```

```
In [292]: s.dt.seconds
```

Out [292]:

```
0      5  
1      6  
2      7  
3      8  
dtype: int64
```

```
In [293]: s.dt.components
```

Out [293] :

days	hours	minutes	seconds	milliseconds	microseconds	nanoseconds
0	1	0	0	5	0	0
1	1	0	0	6	0	0
2	1	0	0	7	0	0
3	1	0	0	8	0	0

Note: Series.dt will raise a `TypeError` if you access with a non-datetime-like values.

2.4.10 Vectorized string methods

Series is equipped with a set of string processing methods that make it easy to operate on each element of the array. Perhaps most importantly, these methods exclude missing/NA values automatically. These are accessed via the Series's `str` attribute and generally have names matching the equivalent (scalar) built-in string methods. For example:

```
In [295]: s.str.lower()
```

Out[295]:

0	a
1	b
2	c
3	aaba
4	baca
5	<NA>
6	caba
7	dog

(continues on next page)

(continued from previous page)

```
8     cat
dtype: string
```

Powerful pattern-matching methods are provided as well, but note that pattern-matching generally uses regular expressions by default (and in some cases always uses them).

Note: Prior to pandas 1.0, string methods were only available on `object`-dtype `Series`. Pandas 1.0 added the `StringDtype` which is dedicated to strings. See [Text Data Types](#) for more.

Please see [Vectorized String Methods](#) for a complete description.

2.4.11 Sorting

Pandas supports three kinds of sorting: sorting by index labels, sorting by column values, and sorting by a combination of both.

By index

The `Series.sort_index()` and `DataFrame.sort_index()` methods are used to sort a pandas object by its index levels.

```
In [296]: df = pd.DataFrame({
.....:     'one': pd.Series(np.random.randn(3), index=['a', 'b', 'c']),

c -1.445975
d  0.669242
Name: three, dtype: float64
```

By values

The `Series.sort_values()` method is used to sort a *Series* by its values. The `DataFrame.sort_values()` method is used to sort a *DataFrame* by its column or row values. The optional `by` parameter to `DataFrame.sort_values()` may be used to specify one or more columns to use to determine the sorted order.

```
In [303]: df1 = pd.DataFrame({'one': [2, 1, 1, 1],
.....:                  'two': [1, 3, 2, 4],
.....:                  'three': [5, 4, 3, 2]})

In [304]: df1.sort_values(by='two')
Out[304]:
    one  two  three
0     2     1     5
2     1     2     3
1     1     3     4
3     1     4     2
```

The `by` parameter can take a list of column names, e.g.:

```
In [305]: df1[['one', 'two', 'three']].sort_values(by=['one', 'two'])
Out[305]:
    one  two  three
2     1     2     3
1     1     3     4
3     1     4     2
0     2     1     5
```

These methods have special treatment of NA values via the `na_position` argument:

```
In [306]: s[2] = np.nan
In [307]: s.sort_values()
```

(continues on next page)

(continued from previous page)

```
Out[307]:  
0      A  
3    Aaba  
1      B  
4   Baca  
6   CABA  
8    cat  
7    dog  
2    <NA>  
5    <NA>  
dtype: string  
  
In [308]: s.sort_values(na_position='first')  
Out[308]:  
2    <NA>  
5    <NA>  
0      A  
3    Aaba  
1      B  
4   Baca  
6   CABA  
8    cat  
7    dog  
dtype: string
```

By indexes and values

New in version 0.23.0.

Strings passed as the `by` parameter to `DataFrame.sort_values()` may refer to either columns or index level names.

```
# Build MultiIndex  
In [309]: idx = pd.MultiIndex.from_tuples([('a', 1), ('a', 2), ('a', 2),  
.....:                               ('b', 2), ('b', 1), ('b', 1)])  
.....:  
  
In [310]: idx.names = ['first', 'second']  
  
# Build DataFrame  
In [311]: df_multi = pd.DataFrame({'A': np.arange(6, 0, -1)},  
.....:                           index=idx)  
.....:  
  
In [312]: df_multi  
Out[312]:  
          A  
first second  
a      1      6  
      2      5  
      2      4  
b      2      3  
      1      2  
      1      1
```

Sort by ‘second’ (index) and ‘A’ (column)

```
In [313]: df_multi.sort_values(by=['second', 'A'])
Out[313]:
   A
first second
b      1      1
      1      2
a      1      6
b      2      3
a      2      4
      2      5
```

Note: If a string matches both a column name and an index level name then a warning is issued and the column takes precedence. This will result in an ambiguity error in a future version.

searchsorted

Series has the `searchsorted()` method, which works similarly to `numpy.ndarray.searchsorted()`.

```
In [314]: ser = pd.Series([1, 2, 3])

In [315]: ser.searchsorted([0, 3])
Out[315]: array([0, 2])

In [316]: ser.searchsorted([0, 4])
Out[316]: array([0, 3])

In [317]: ser.searchsorted([1, 3], side='right')
Out[317]: array([1, 3])

In [318]: ser.searchsorted([1, 3], side='left')
Out[318]: array([0, 2])

In [319]: ser = pd.Series([3, 1, 2])

In [320]: ser.searchsorted([0, 3], sorter=np.argsort(ser))
Out[320]: array([0, 2])
```

smallest / largest values

Series has the `nsmallest()` and `nlargest()` methods which return the smallest or largest n values. For a large Series this can be much faster than sorting the entire Series and calling `head(n)` on the result.

```
In [321]: s = pd.Series(np.random.permutation(10))

In [322]: s
Out[322]:
0     8
1     3
2     1
3     0
4     7
5     4
```

(continues on next page)

(continued from previous page)

```
6    2
7    6
8    5
9    9
dtype: int64

In [323]: s.sort_values()
Out[323]:
3    0
2    1
6    2
1    3
5    4
8    5
7    6
4    7
0    8
9    9
dtype: int64

In [324]: s.nsmallest(3)
Out[324]:
3    0
2    1
6    2
dtype: int64

In [325]: s.nlargest(3)
Out[325]:
9    9
0    8
4    7
dtype: int64
```

DataFrame also has the nlargest and nsmallest methods.

```
In [326]: df = pd.DataFrame({'a': [-2, -1, 1, 10, 8, 11, -1],
.....:                 'b': list('abdceff'),
.....:                 'c': [1.0, 2.0, 4.0, 3.2, np.nan, 3.0, 4.0]})

In [327]: df.nlargest(3, 'a')
Out[327]:
   a   b   c
5  11   f  3.0
3  10   c  3.2
4   8   e  NaN

In [328]: df.nlargest(5, ['a', 'c'])
Out[328]:
   a   b   c
5  11   f  3.0
3  10   c  3.2
4   8   e  NaN
2   1   d  4.0
6  -1   f  4.0
```

(continues on next page)

(continued from previous page)

```
In [329]: df.nsmallest(3, 'a')
Out[329]:
   a    b    c
0 -2   a  1.0
1 -1   b  2.0
6 -1   f  4.0

In [330]: df.nsmallest(5, ['a', 'c'])
Out[330]:
   a    b    c
0 -2   a  1.0
1 -1   b  2.0
6 -1   f  4.0
2  1   d  4.0
4  8   e  NaN
```

Sorting by a MultiIndex column

You must be explicit about sorting when the column is a MultiIndex, and fully specify all levels to `by`.

```
In [331]: df1.columns = pd.MultiIndex.from_tuples([('a', 'one'),
.....:                               ('a', 'two'),
.....:                               ('b', 'three')])
.....:

In [332]: df1.sort_values(by=('a', 'two'))
Out[332]:
      a        b
  one two three
0    2    1    5
2    1    2    3
1    1    3    4
3    1    4    2
```

2.4.12 Copying

The `copy()` method on pandas objects copies the underlying data (though not the axis indexes, since they are immutable) and returns a new object. Note that **it is seldom necessary to copy objects**. For example, there are only a handful of ways to alter a DataFrame *in-place*:

- Inserting, deleting, or modifying a column.
- Assigning to the `index` or `columns` attributes.
- For homogeneous data, directly modifying the values via the `values` attribute or advanced indexing.

To be clear, no pandas method has the side effect of modifying your data; almost every method returns a new object, leaving the original object untouched. If the data is modified, it is because you did so explicitly.

2.4.13 dtypes

For the most part, pandas uses NumPy arrays and dtypes for Series or individual columns of a DataFrame. NumPy provides support for float, int, bool, timedelta64 [ns] and datetime64 [ns] (note that NumPy does not support timezone-aware datetimes).

Pandas and third-party libraries *extend* NumPy’s type system in a few places. This section describes the extensions pandas has made internally. See [Extension types](#) for how to write your own extension that works with pandas. See `ecosystem.extensions` for a list of third-party libraries that have implemented an extension.

The following table lists all of pandas extension types. For methods requiring `dtype` arguments, strings can be specified as indicated. See the respective documentation sections for more on each type.

Kind of Data	Data Type	Scalar Array	String Aliases	Documentation
tz-aware datetime	DatetimeDtype	DatetimeArray	'datetime64[ns, <tz>]' DatetimeArray	Time zone handling
Categorical	CategoricalDtype	CategoricalArray	'category'	categorical
period (time spans)	PeriodDtype	PeriodArray	'period[<freq>]', 'Period[<freq>]' PeriodArray	Time span representation
sparse	SparseDtype	SparseArray	'Sparse', 'Sparse[int]', 'Sparse[float]' SparseArray	sparse
intervals	IntervalDtype	IntervalArray	'interval', 'Interval' 'Interval[<numpy_dtype>]', 'Interval[datetime64[ns, <tz>>]]', 'Interval[timedelta64[<freq>>]]'	IntervalIndex
nullable integer	Int64Dtype	IntegerArray	'Int8', 'Int16', 'Int32', 'Int64', 'UInt8', 'UInt16', 'UInt32', 'UInt64'	Nullable integer data type
Strings	StringDtype	StringArray	'string'	text
Boolean (with NA)	BooleanDtype	BooleanArray	'boolean'	Boolean data with missing values

Pandas has two ways to store strings.

1. `object` dtype, which can hold any Python object, including strings.
 2. `StringDtype`, which is dedicated to strings.

Generally, we recommend using `StringDtype`. See [Text Data Types](#) for more.

Finally, arbitrary objects may be stored using the `object` dtype, but should be avoided to the extent possible (for performance and interoperability with other libraries and methods. See [object conversion](#)).

A convenient `dtypes` attribute for DataFrame returns a Series with the data type of each column.

```
In [333]: dft = pd.DataFrame({ 'A': np.random.rand(3),
.....:             'B': 1,
.....:             'C': 'foo',
.....:             'D': pd.Timestamp('20010102'),
.....:             'E': pd.Series([1.0] * 3).astype('float32'),
.....:             'F': False,
.....:             'G': pd.Series([1] * 3, dtype='int8')})
.....:

In [334]: dft
Out[334]:
   A    B    C          D      E      F    G
0  0.993576  1  foo 2001-01-02  1.0  False  1
1  0.067501  1  foo 2001-01-02  1.0  False  1
2  0.568226  1  foo 2001-01-02  1.0  False  1

In [335]: dft.dtypes
Out[335]:
A           float64
B          int64
C          object
D  datetime64[ns]
E         float32
F         bool
G          int8
dtype: object
```

On a Series object, use the `dtype` attribute.

```
In [336]: dft['A'].dtype
Out[336]: dtype('float64')
```

If a pandas object contains data with multiple dtypes *in a single column*, the dtype of the column will be chosen to accommodate all of the data types (object is the most general).

```
# these ints are coerced to floats
In [337]: pd.Series([1, 2, 3, 4, 5, 6.])
Out[337]:
0    1.0
1    2.0
2    3.0
3    4.0
4    5.0
5    6.0
dtype: float64

# string data forces an ``object`` dtype
In [338]: pd.Series([1, 2, 3, 6., 'foo'])
Out[338]:
0      1
1      2
2      3
3      6
4    foo
dtype: object
```

The number of columns of each type in a DataFrame can be found by calling `DataFrame.dtypes.value_counts()`.

```
In [339]: dft.dtypes.value_counts()
Out[339]:
int8          1
bool          1
float32       1
datetime64[ns] 1
int64          1
object          1
float64        1
dtype: int64
```

Numeric dtypes will propagate and can coexist in DataFrames. If a dtype is passed (either directly via the `dtype` keyword, a passed ndarray, or a passed Series), then it will be preserved in DataFrame operations. Furthermore, different numeric dtypes will **NOT** be combined. The following example will give you a taste.

```
In [340]: df1 = pd.DataFrame(np.random.randn(8, 1), columns=['A'], dtype='float32')
```

```
In [341]: df1
```

```
Out[341]:
A
```

```
0 -0.001665
1  1.077210
2 -0.204770
3  0.013393
4 -2.514156
5 -0.345200
6 -2.152995
7  0.368361
```

```
In [342]: df1.dtypes
```

```
Out[342]:
A    float32
```

```
dtype: object
```

```
In [343]: df2 = pd.DataFrame({'A': pd.Series(np.random.randn(8), dtype='float16'),
.....:                 'B': pd.Series(np.random.randn(8)),
.....:                 'C': pd.Series(np.array(np.random.randn(8),
.....:                           dtype='uint8'))})
```

```
In [344]: df2
```

```
Out[344]:
A      B   C
```

```
0  1.357422 -0.575374  0
1 -0.747559 -1.619321  0
2  0.173096 -2.685205  2
3  1.301758  0.572740  1
4 -1.702148 -0.057228  0
5  0.469971 -3.260906  0
6 -0.644531  0.282847  0
7  1.107422  0.287453  0
```

```
In [345]: df2.dtypes
```

```
Out[345]:
A    float16
B    float64
C     uint8
```

(continues on next page)

(continued from previous page)

```
dtype: object
```

defaults

By default integer types are `int64` and float types are `float64`, *regardless* of platform (32-bit or 64-bit). The following will all result in `int64` dtypes.

```
In [346]: pd.DataFrame([1, 2], columns=['a']).dtypes
Out[346]:
a    int64
dtype: object

In [347]: pd.DataFrame({'a': [1, 2]}).dtypes
Out[347]:
a    int64
dtype: object

In [348]: pd.DataFrame({'a': 1}, index=list(range(2))).dtypes
Out[348]:
a    int64
dtype: object
```

Note that Numpy will choose *platform-dependent* types when creating arrays. The following **WILL** result in `int32` on 32-bit platform.

```
In [349]: frame = pd.DataFrame(np.array([1, 2]))
```

upcasting

Types can potentially be *upcasted* when combined with other types, meaning they are promoted from the current type (e.g. `int` to `float`).

```
In [350]: df3 = df1.reindex_like(df2).fillna(value=0.0) + df2

In [351]: df3
Out[351]:
       A         B         C
0  1.355757 -0.575374  0.0
1  0.329652 -1.619321  0.0
2 -0.031674 -2.685205  2.0
3  1.315151  0.572740  1.0
4 -4.216304 -0.057228  0.0
5  0.124771 -3.260906  0.0
6 -2.797526  0.282847  0.0
7  1.475783  0.287453  0.0

In [352]: df3.dtypes
Out[352]:
A    float32
B    float64
C    float64
dtype: object
```

`DataFrame.to_numpy()` will return the *lower-common-denominator* of the dtypes, meaning the dtype that can accommodate **ALL** of the types in the resulting homogeneous dtypes NumPy array. This can force some *upcasting*.

```
In [353]: df3.to_numpy().dtype
Out[353]: dtype('float64')
```

astype

You can use the `astype()` method to explicitly convert dtypes from one to another. These will by default return a copy, even if the dtype was unchanged (pass `copy=False` to change this behavior). In addition, they will raise an exception if the astype operation is invalid.

Upcasting is always according to the **numpy** rules. If two different dtypes are involved in an operation, then the more *general* one will be used as the result of the operation.

```
In [354]: df3
Out[354]:
   A          B          C
0  1.355757 -0.575374  0.0
1  0.329652 -1.619321  0.0
2 -0.031674 -2.685205  2.0
3  1.315151  0.572740  1.0
4 -4.216304 -0.057228  0.0
5  0.124771 -3.260906  0.0
6 -2.797526  0.282847  0.0
7  1.475783  0.287453  0.0

2  True  6  9.0

In [364]: dft1.dtypes
Out[364]:
a      bool
b      int64
c    float64
dtype: object
```

Note: When trying to convert a subset of columns to a specified type using `astype()` and `loc()`, upcasting occurs.

`loc()` tries to fit in what we are assigning to the current dtypes, while `[]` will overwrite them taking the dtype from the right hand side. Therefore the following piece of code produces the unintended result.

```
In [365]: dft = pd.DataFrame({'a': [1, 2, 3], 'b': [4, 5, 6], 'c': [7, 8, 9]})

In [366]: dft.loc[:, ['a', 'b']].astype(np.uint8).dtypes
Out[366]:
a    uint8
b    uint8
dtype: object

In [367]: dft.loc[:, ['a', 'b']] = dft.loc[:, ['a', 'b']].astype(np.uint8)

In [368]: dft.dtypes
Out[368]:
a    int64
b    int64
c    int64
dtype: object
```

object conversion

pandas offers various functions to try to force conversion of types from the `object` dtype to other types. In cases where the data is already of the correct type, but stored in an `object` array, the `DataFrame.infer_objects()` and `Series.infer_objects()` methods can be used to soft convert to the correct type.

```
In [369]: import datetime

In [370]: df = pd.DataFrame([[1, 2],
   .....:                   ['a', 'b'],
   .....:                   [datetime.datetime(2016, 3, 2),
   .....:                    datetime.datetime(2016, 3, 2)]])
   ......

In [371]: df = df.T

In [372]: df
Out[372]:
   0   1      2
0   1   a 2016-03-02
1   2   b 2016-03-02

In [373]: df.dtypes
Out[373]:
0          object
1          object
2    datetime64[ns]
dtype: object
```

Because the data was transposed the original inference stored all columns as `object`, which `infer_objects` will correct.

```
In [374]: df.infer_objects().dtypes
Out[374]:
0          int64
1          object
2    datetime64[ns]
dtype: object
```

The following functions are available for one dimensional object arrays or scalars to perform hard conversion of objects to a specified type:

- `to_numeric()` (conversion to numeric dtypes)

```
In [375]: m = ['1.1', 2, 3]
```

```
In [376]: pd.to_numeric(m)
Out[376]: array([1.1, 2., 3.])
```

- `to_datetime()` (conversion to datetime objects)

```
In [377]: import datetime
```

```
In [378]: m = ['2016-07-09', datetime.datetime(2016, 3, 2)]
```

```
In [379]: pd.to_datetime(m)
Out[379]: DatetimeIndex(['2016-07-09', '2016-03-02'], dtype='datetime64[ns]', freq=None)
```

- `to_timedelta()` (conversion to timedelta objects)

```
In [380]: m = ['5us', pd.Timedelta('1day')]

In [381]: pd.to_timedelta(m)
Out[381]: TimedeltaIndex(['0 days 00:00:00.000005', '1 days 00:00:00'], dtype='timedelta64[ns]', freq=None)
```

To force a conversion, we can pass in an `errors` argument, which specifies how pandas should deal with elements that cannot be converted to desired dtype or object. By default, `errors='raise'`, meaning that any errors encountered will be raised during the conversion process. However, if `errors='coerce'`, these errors will be ignored and pandas will convert problematic elements to `pd.NaT` (for datetime and timedelta) or `np.nan` (for numeric). This might be useful if you are reading in data which is mostly of the desired dtype (e.g. numeric, datetime), but occasionally has non-conforming elements intermixed that you want to represent as missing:

```
In [382]: import datetime

In [383]: m = ['apple', datetime.datetime(2016, 3, 2)]

In [384]: pd.to_datetime(m, errors='coerce')
Out[384]: DatetimeIndex(['NaT', '2016-03-02'], dtype='datetime64[ns]', freq=None)

In [385]: m = ['apple', 2, 3]

In [386]: pd.to_numeric(m, errors='coerce')
Out[386]: array([nan, 2., 3.])

In [387]: m = ['apple', pd.Timedelta('1day')]

In [388]: pd.to_timedelta(m, errors='coerce')
Out[388]: TimedeltaIndex([NaT, '1 days'], dtype='timedelta64[ns]', freq=None)
```

The `errors` parameter has a third option of `errors='ignore'`, which will simply return the passed in data if it encounters any errors with the conversion to a desired data type:

```
In [389]: import datetime

In [390]: m = ['apple', datetime.datetime(2016, 3, 2)]

In [391]: pd.to_datetime(m, errors='ignore')
Out[391]: Index(['apple', 2016-03-02 00:00:00], dtype='object')

In [392]: m = ['apple', 2, 3]

In [393]: pd.to_numeric(m, errors='ignore')
Out[393]: array(['apple', 2, 3], dtype=object)

In [394]: m = ['apple', pd.Timedelta('1day')]

In [395]: pd.to_timedelta(m, errors='ignore')
Out[395]: array(['apple', Timedelta('1 days 00:00:00')], dtype=object)
```

In addition to object conversion, `to_numeric()` provides another argument `downcast`, which gives the option of downcasting the newly (or already) numeric data to a smaller dtype, which can conserve memory:

```
In [396]: m = [1, 2, 3]
```

(continues on next page)

(continued from previous page)

```
In [397]: pd.to_numeric(m, downcast='integer')      # smallest signed int dtype
Out[397]: array([1, 2, 3], dtype=int8)

In [398]: pd.to_numeric(m, downcast='signed')        # same as 'integer'
Out[398]: array([1, 2, 3], dtype=int8)

In [399]: pd.to_numeric(m, downcast='unsigned')       # smallest unsigned int dtype
Out[399]: array([1, 2, 3], dtype=uint8)

In [400]: pd.to_numeric(m, downcast='float')         # smallest float dtype
Out[400]: array([1., 2., 3.], dtype=float32)
```

As these methods apply only to one-dimensional arrays, lists or scalars; they cannot be used directly on multi-dimensional objects such as DataFrames. However, with `apply()`, we can “apply” the function over each column efficiently:

```
In [401]: import datetime

In [402]: df = pd.DataFrame([
.....:     ['2016-07-09', datetime.datetime(2016, 3, 2)] * 2, dtype='O')
.....:

In [403]: df
Out[403]:
   0           1
0 2016-07-09 2016-03-02 00:00:00
1 2016-07-09 2016-03-02 00:00:00

In [404]: df.apply(pd.to_datetime)
Out[404]:
   0           1
0 2016-07-09 2016-03-02
1 2016-07-09 2016-03-02

In [405]: df = pd.DataFrame([[1.1, 2, 3] * 2, dtype='O')

In [406]: df
Out[406]:
   0  1  2
0  1.1 2  3
1  1.1 2  3

In [407]: df.apply(pd.to_numeric)
Out[407]:
   0  1  2
0  1.1 2  3
1  1.1 2  3

In [408]: df = pd.DataFrame([[5us, pd.Timedelta('1day')]] * 2, dtype='O')

In [409]: df
Out[409]:
   0           1
0 5us 1 days 00:00:00
1 5us 1 days 00:00:00
```

(continues on next page)

(continued from previous page)

```
In [410]: df.apply(pd.to_timedelta)
Out[410]:
          0      1
0 00:00:00.000005 1 days
1 00:00:00.000005 1 days
```

gotchas

Performing selection operations on `integer` type data can easily upcast the data to `floating`. The `dtype` of the input data will be preserved in cases where `nans` are not introduced. See also [Support for integer NA](#).

```
In [411]: dfi = df3.astype('int32')

In [412]: dfi['E'] = 1

In [413]: dfi
Out[413]:
   A   B   C   E
0  1  0  0  1
1  0 -1  0  1
2  0 -2  2  1
3  1  0  1  1
4 -4  0  0  1
5  0 -3  0  1
6 -2  0  0  1
7  1  0  0  1

In [414]: dfi.dtypes
Out[414]:
A    int32
B    int32
C    int32
E    int64
dtype: object

In [415]: casted = dfi[dfi > 0]

In [416]: casted
Out[416]:
   A   B   C   E
0  1.0  NaN  NaN  1
1  NaN  NaN  NaN  1
2  NaN  NaN  2.0  1
3  1.0  NaN  1.0  1
4  NaN  NaN  NaN  1
5  NaN  NaN  NaN  1
6  NaN  NaN  NaN  1
7  1.0  NaN  NaN  1

In [417]: casted.dtypes
Out[417]:
A    float64
B    float64
C    float64
E    int64
```

(continues on next page)

(continued from previous page)

dtype: object

While float dtypes are unchanged.

```
In [418]: dfa = df3.copy()

In [419]: dfa['A'] = dfa['A'].astype('float32')

In [420]: dfa.dtypes
Out[420]:
A    float32
B    float64
C    float64
dtype: object

In [421]: casted = dfa[df2 > 0]

In [422]: casted
Out[422]:
      A      B      C
0  1.355757    NaN    NaN
1      NaN    NaN    NaN
2 -0.031674    NaN  2.0
3  1.315151  0.572740  1.0
4      NaN    NaN    NaN
5  0.124771    NaN    NaN
6      NaN  0.282847    NaN
7  1.475783  0.287453    NaN

In [423]: casted.dtypes
Out[423]:
A    float32
B    float64
C    float64
dtype: object
```

2.4.14 Selecting columns based on dtype

The `select_dtypes()` method implements subsetting of columns based on their `dtype`.

First, let's create a `DataFrame` with a slew of different dtypes:

```
In [424]: df = pd.DataFrame({'string': list('abc'),
.....:                 'int64': list(range(1, 4)),
.....:                 'uint8': np.arange(3, 6).astype('u1'),
.....:                 'float64': np.arange(4.0, 7.0),
.....:                 'bool1': [True, False, True],
.....:                 'bool2': [False, True, False],
.....:                 'dates': pd.date_range('now', periods=3),
.....:                 'category': pd.Series(list("ABC")).astype('category')})

In [425]: df['tdeltas'] = df.dates.diff()

In [426]: df['uint64'] = np.arange(3, 6).astype('u8')
```

(continues on next page)

(continued from previous page)

```
In [427]: df['other_dates'] = pd.date_range('20130101', periods=3)

In [428]: df['tz_aware_dates'] = pd.date_range('20130101', periods=3, tz='US/Eastern')

In [429]: df
Out[429]:
   string  int64  uint8  float64  bool1  bool2          dates  category
0      a      1       3       4.0    True   False  2020-03-09 18:38:21.047735      A
1     NaT      3  2013-01-01 2013-01-01 00:00:00-05:00
2      b      2       4       5.0   False   True  2020-03-10 18:38:21.047735      B
3     days      4  2013-01-02 2013-01-02 00:00:00-05:00
4      c      3       5       6.0    True   False  2020-03-11 18:38:21.047735      C
5     days      5  2013-01-03 2013-01-03 00:00:00-05:00
```

And the dtypes:

```
In [430]: df.dtypes
Out[430]:
string          object
int64           int64
uint8           uint8
float64         float64
bool1           bool
bool2           bool
dates           datetime64[ns]
category        category
tdeltas         timedelta64[ns]
uint64           uint64
other_dates     datetime64[ns]
tz_aware_dates  datetime64[ns, US/Eastern]
dtype: object
```

`select_dtypes()` has two parameters `include` and `exclude` that allow you to say “give me the columns *with* these dtypes” (`include`) and/or “give the columns *without* these dtypes” (`exclude`).

For example, to select `bool` columns:

```
In [431]: df.select_dtypes(include=[bool])
Out[431]:
   bool1  bool2
0   True  False
1  False  True
2   True  False
```

You can also pass the name of a dtype in the NumPy dtype hierarchy:

```
In [432]: df.select_dtypes(include=['bool'])
Out[432]:
   bool1  bool2
0   True  False
1  False  True
2   True  False
```

`select_dtypes()` also works with generic dtypes as well.

For example, to select all numeric and boolean columns while excluding unsigned integers:

```
In [433]: df.select_dtypes(include=['number', 'bool'], exclude=['unsignedinteger'])
Out[433]:
   int64  float64  bool1  bool2  tdeltas
0      1       4.0    True   False     NaT
1      2       5.0   False   True  1 days
2      3       6.0    True  False  1 days
```

To select string columns you must use the `object` dtype:

```
In [434]: df.select_dtypes(include=['object'])
Out[434]:
   string
0      a
1      b
2      c
```

To see all the child dtypes of a generic dtype like `numpy.number` you can define a function that returns a tree of child dtypes:

```
In [435]: def subdtypes(dtype):
.....:     subs = dtype.__subclasses__()
.....:     if not subs:
.....:         return dtype
.....:     return [dtype, [subdtypes(dt) for dt in subs]]
.....:
```

All NumPy dtypes are subclasses of `numpy.generic`:

```
In [436]: subdtypes(np.generic)
Out[436]:
[numpy.generic,
 [[numpy.number,
  [[numpy.integer,
   [[numpy.signedinteger,
    [numpy.int8,
     numpy.int16,
     numpy.int32,
     numpy.int64,
     numpy.longlong,
     numpy.timedelta64]],
    [numpy.unsignedinteger,
     [numpy.uint8,
      numpy.uint16,
      numpy.uint32,
      numpy.uint64,
      numpy.ulonglong]]],
   [numpy.inexact,
    [[numpy.floating,
     [numpy.float16, numpy.float32, numpy.float64, numpy.float128]],
     [numpy.complexfloating,
      [numpy.complex64, numpy.complex128, numpy.complex256]]]]],
  [numpy.flexible,
   [[numpy.character, [numpy.bytes_, numpy.str_]],
    [numpy.void, [numpy.record]]]],
  numpy.bool_,
  numpy.datetime64,
  numpy.object_]]]
```

Note: Pandas also defines the types `category`, and `datetime64[ns, tz]`, which are not integrated into the normal NumPy hierarchy and won't show up with the above function.

```
{ { header } }
```

2.5 Intro to data structures

We'll start with a quick, non-comprehensive overview of the fundamental data structures in pandas to get you started. The fundamental behavior about data types, indexing, and axis labeling / alignment apply across all of the objects. To get started, import NumPy and load pandas into your namespace:

```
In [1]: import numpy as np
```

```
In [2]: import pandas as pd
```

Here is a basic tenet to keep in mind: **data alignment is intrinsic**. The link between labels and data will not be broken unless done so explicitly by you.

We'll give a brief intro to the data structures, then consider all of the broad categories of functionality and methods in separate sections.

2.5.1 Series

`Series` is a one-dimensional labeled array capable of holding any data type (integers, strings, floating point numbers, Python objects, etc.). The axis labels are collectively referred to as the **index**. The basic method to create a Series is to call:

```
>>> s = pd.Series(data, index=index)
```

Here, `data` can be many different things:

- a Python dict
- an ndarray
- a scalar value (like 5)

The passed `index` is a list of axis labels. Thus, this separates into a few cases depending on what **data is**:

From ndarray

If `data` is an ndarray, `index` must be the same length as `data`. If no index is passed, one will be created having values `[0, ..., len(data) - 1]`.

```
In [3]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])
```

```
In [4]: s
```

```
Out[4]:
```

a	0.683418
b	-2.028100
c	-1.562428
d	-0.315958
e	0.317282
	dtype: float64

(continues on next page)

(continued from previous page)

```
In [5]: s.index
Out[5]: Index(['a', 'b', 'c', 'd', 'e'], dtype='object')

In [6]: pd.Series(np.random.randn(5))
Out[6]:
0    0.003147
1   -0.108592
2   -0.997011
3    0.273130
4    0.505116
dtype: float64
```

Note: pandas supports non-unique index values. If an operation that does not support duplicate index values is attempted, an exception will be raised at that time. The reason for being lazy is nearly all performance-based (there are many instances in computations, like parts of GroupBy, where the index is not used).

From dict

Series can be instantiated from dicts:

```
In [7]: d = {'b': 1, 'a': 0, 'c': 2}

In [8]: pd.Series(d)
Out[8]:
b    1
a    0
c    2
dtype: int64
```

Note: When the data is a dict, and an index is not passed, the Series index will be ordered by the dict's insertion order, if you're using Python version ≥ 3.6 and Pandas version ≥ 0.23 .

If you're using Python < 3.6 or Pandas < 0.23 , and an index is not passed, the Series index will be the lexically ordered list of dict keys.

In the example above, if you were on a Python version lower than 3.6 or a Pandas version lower than 0.23, the Series would be ordered by the lexical order of the dict keys (i.e. ['a', 'b', 'c'] rather than ['b', 'a', 'c']).

If an index is passed, the values in data corresponding to the labels in the index will be pulled out.

```
In [9]: d = {'a': 0., 'b': 1., 'c': 2.}

In [10]: pd.Series(d)
Out[10]:
a    0.0
b    1.0
c    2.0
dtype: float64

In [11]: pd.Series(d, index=['b', 'c', 'd', 'a'])
Out[11]:
b    1.0
c    2.0
```

(continues on next page)

(continued from previous page)

```
d      NaN
a      0.0
dtype: float64
```

Note: NaN (not a number) is the standard missing data marker used in pandas.

From scalar value

If data is a scalar value, an index must be provided. The value will be repeated to match the length of `index`.

```
In [12]: pd.Series(5., index=['a', 'b', 'c', 'd', 'e'])
Out[12]:
a    5.0
b    5.0
c    5.0
d    5.0
e    5.0
dtype: float64
```

Series is ndarray-like

`Series` acts very similarly to a `ndarray`, and is a valid argument to most NumPy functions. However, operations such as slicing will also slice the index.

```
In [13]: s[0]
Out[13]: 0.683418480946376

In [14]: s[:3]
Out[14]:
a    0.683418
b   -2.028100
c   -1.562428
dtype: float64

In [15]: s[s > s.median()]
Out[15]:
a    0.683418
e    0.317282
dtype: float64

In [16]: s[[4, 3, 1]]
Out[16]:
e    0.317282
d   -0.315958
b   -2.028100
dtype: float64

In [17]: np.exp(s)
Out[17]:
a    1.980637
b    0.131585
c    0.209626
d    0.729090
```

(continues on next page)

(continued from previous page)

```
e    1.373390
dtype: float64
```

Note: We will address array-based indexing like `s[[4, 3, 1]]` in [section](#).

Like a NumPy array, a pandas Series has a `dtype`.

```
In [18]: s.dtype
Out[18]: dtype('float64')
```

This is often a NumPy `dtype`. However, pandas and 3rd-party libraries extend NumPy's type system in a few places, in which case the `dtype` would be a [ExtensionDtype](#). Some examples within pandas are categorical and [Nullable integer data type](#). See [dtypes](#) for more.

If you need the actual array backing a Series, use `Series.array`.

```
In [19]: s.array
Out[19]:
<PandasArray>
[ 0.683418480946376, -2.0281001111044286, -1.5624280130633477,
 -0.31595765833264, 0.31728244097420916]
Length: 5, dtype: float64
```

Accessing the array can be useful when you need to do some operation without the index (to disable [automatic alignment](#), for example).

`Series.array` will always be an [ExtensionArray](#). Briefly, an ExtensionArray is a thin wrapper around one or more [concrete arrays](#) like a `numpy.ndarray`. Pandas knows how to take an ExtensionArray and store it in a Series or a column of a DataFrame. See [dtypes](#) for more.

While Series is ndarray-like, if you need an *actual* ndarray, then use `Series.to_numpy()`.

```
In [20]: s.to_numpy()
Out[20]: array([ 0.68341848, -2.02810011, -1.56242801, -0.31595766, 0.31728244])
```

Even if the Series is backed by a [ExtensionArray](#), `Series.to_numpy()` will return a NumPy ndarray.

Series is dict-like

A Series is like a fixed-size dict in that you can get and set values by index label:

```
In [21]: s['a']
Out[21]: 0.683418480946376

In [22]: s['e'] = 12.

In [23]: s
Out[23]:
a      0.683418
b     -2.028100
c     -1.562428
d     -0.315958
e      12.000000
dtype: float64
```

(continues on next page)

(continued from previous page)

```
In [24]: 'e' in s
Out[24]: True
```

```
In [25]: 'f' in s
Out[25]: False
```

If a label is not contained, an exception is raised:

```
>>> s['f']
KeyError: 'f'
```

Using the `get` method, a missing label will return `None` or specified default:

```
In [26]: s.get('f')
```

```
In [27]: s.get('f', np.nan)
Out[27]: nan
```

See also the [section on attribute access](#).

Vectorized operations and label alignment with Series

When working with raw NumPy arrays, looping through value-by-value is usually not necessary. The same is true when working with Series in pandas. Series can also be passed into most NumPy methods expecting an ndarray.

```
In [28]: s + s
```

```
Out[28]:
a      1.366837
b     -4.056200
c     -3.124856
d     -0.631915
e     24.000000
dtype: float64
```

```
In [29]: s * 2
```

```
Out[29]:
a      1.366837
b     -4.056200
c     -3.124856
d     -0.631915
e     24.000000
dtype: float64
```

```
In [30]: np.exp(s)
```

```
Out[30]:
a      1.980637
b      0.131585
c      0.209626
d      0.729090
e    162754.791419
dtype: float64
```

A key difference between Series and ndarray is that operations between Series automatically align the data based on label. Thus, you can write computations without giving consideration to whether the Series involved have the same labels.

```
In [31]: s[1:] + s[:-1]
```

```
Out[31]:
```

```
a      NaN  
b    -4.056200  
c    -3.124856  
d    -0.631915  
e      NaN  
dtype: float64
```

The result of an operation between unaligned Series will have the **union** of the indexes involved. If a label is not found in one Series or the other, the result will be marked as missing NaN. Being able to write code without doing any explicit data alignment grants immense freedom and flexibility in interactive data analysis and research. The integrated data alignment features of the pandas data structures set pandas apart from the majority of related tools for working with labeled data.

Note: In general, we chose to make the default result of operations between differently indexed objects yield the **union** of the indexes in order to avoid loss of information. Having an index label, though the data is missing, is typically important information as part of a computation. You of course have the option of dropping labels with missing data via the **dropna** function.

Name attribute

Series can also have a name attribute:

```
In [32]: s = pd.Series(np.random.randn(5), name='something')
```

```
In [33]: s
```

```
Out[33]:
```

```
0    -1.425277  
1    -1.067976  
2    -0.412608  
3     1.526176  
4     0.218512  
Name: something, dtype: float64
```

```
In [34]: s.name
```

```
Out[34]: 'something'
```

The Series name will be assigned automatically in many cases, in particular when taking 1D slices of DataFrame as you will see below.

You can rename a Series with the `pandas.Series.rename()` method.

```
In [35]: s2 = s.rename("different")
```

```
In [36]: s2.name
```

```
Out[36]: 'different'
```

Note that `s` and `s2` refer to different objects.

2.5.2 DataFrame

DataFrame is a 2-dimensional labeled data structure with columns of potentially different types. You can think of it like a spreadsheet or SQL table, or a dict of Series objects. It is generally the most commonly used pandas object. Like Series, DataFrame accepts many different kinds of input:

- Dict of 1D ndarrays, lists, dicts, or Series
- 2-D numpy.ndarray
- Structured or record ndarray
- A Series
- Another DataFrame

Along with the data, you can optionally pass **index** (row labels) and **columns** (column labels) arguments. If you pass an index and / or columns, you are guaranteeing the index and / or columns of the resulting DataFrame. Thus, a dict of Series plus a specific index will discard all data not matching up to the passed index.

If axis labels are not passed, they will be constructed from the input data based on common sense rules.

Note: When the data is a dict, and `columns` is not specified, the DataFrame columns will be ordered by the dict's insertion order, if you are using Python version >= 3.6 and Pandas >= 0.23.

If you are using Python < 3.6 or Pandas < 0.23, and `columns` is not specified, the DataFrame columns will be the lexically ordered list of dict keys.

From dict of Series or dicts

The resulting **index** will be the **union** of the indexes of the various Series. If there are any nested dicts, these will first be converted to Series. If no columns are passed, the columns will be the ordered list of dict keys.

```
In [37]: d = {'one': pd.Series([1., 2., 3.], index=['a', 'b', 'c']),
....:      'two': pd.Series([1., 2., 3., 4.], index=['a', 'b', 'c', 'd'])}
....:

In [38]: df = pd.DataFrame(d)

In [39]: df
Out[39]:
   one  two
a  1.0  1.0
b  2.0  2.0
c  3.0  3.0
d  NaN  4.0

In [40]: pd.DataFrame(d, index=['d', 'b', 'a'])
Out[40]:
   one  two
d  NaN  4.0
b  2.0  2.0
a  1.0  1.0

In [41]: pd.DataFrame(d, index=['d', 'b', 'a'], columns=['two', 'three'])
Out[41]:
   two  three
```

(continues on next page)

(continued from previous page)

```
d    4.0    NaN  
b    2.0    NaN  
a    1.0    NaN
```

The row and column labels can be accessed respectively by accessing the **index** and **columns** attributes:

Note: When a particular set of columns is passed along with a dict of data, the passed columns override the keys in the dict.

```
In [42]: df.index  
Out[42]: Index(['a', 'b', 'c', 'd'], dtype='object')  
  
In [43]: df.columns  
Out[43]: Index(['one', 'two'], dtype='object')
```

From dict of ndarrays / lists

The ndarrays must all be the same length. If an index is passed, it must clearly also be the same length as the arrays. If no index is passed, the result will be `range(n)`, where n is the array length.

```
In [44]: d = {'one': [1., 2., 3., 4.],  
.....:      'two': [4., 3., 2., 1.]}  
.....:  
  
In [45]: pd.DataFrame(d)  
Out[45]:  
   one  two  
0  1.0  4.0  
1  2.0  3.0  
2  3.0  2.0  
3  4.0  1.0  
  
In [46]: pd.DataFrame(d, index=['a', 'b', 'c', 'd'])  
Out[46]:  
   one  two  
a  1.0  4.0  
b  2.0  3.0  
c  3.0  2.0  
d  4.0  1.0
```

From structured or record array

This case is handled identically to a dict of arrays.

```
In [47]: data = np.zeros((2, ), dtype=[('A', 'i4'), ('B', 'f4'), ('C', 'a10')])  
  
In [48]: data[:] = [(1, 2., 'Hello'), (2, 3., "World")]  
  
In [49]: pd.DataFrame(data)  
Out[49]:  
       A      B      C  
0  1.0  2.0  Hello  
1  2.0  3.0  World
```

(continues on next page)

(continued from previous page)

```

0 1 2.0 b'Hello'
1 2 3.0 b'World'

In [50]: pd.DataFrame(data, index=['first', 'second'])
Out[50]:
      A      B      C
first  1  2.0  b'Hello'
second 2  3.0  b'World'

In [51]: pd.DataFrame(data, columns=['C', 'A', 'B'])
Out[51]:
      C      A      B
0  b'Hello'  1  2.0
1  b'World'  2  3.0

```

Note: DataFrame is not intended to work exactly like a 2-dimensional NumPy ndarray.

From a list of dicts

```

In [52]: data2 = [{'a': 1, 'b': 2}, {'a': 5, 'b': 10, 'c': 20}]

In [53]: pd.DataFrame(data2)
Out[53]:
      a      b      c
0  1      2    NaN
1  5     10  20.0

In [54]: pd.DataFrame(data2, index=['first', 'second'])
Out[54]:
      a      b      c
first  1      2    NaN
second 5     10  20.0

In [55]: pd.DataFrame(data2, columns=['a', 'b'])
Out[55]:
      a      b
0  1      2
1  5     10

```

From a dict of tuples

You can automatically create a MultiIndexed frame by passing a tuples dictionary.

```

In [56]: pd.DataFrame({('a', 'b'): {('A', 'B'): 1, ('A', 'C'): 2},
.....:           ('a', 'a'): {('A', 'C'): 3, ('A', 'B'): 4},
.....:           ('a', 'c'): {('A', 'B'): 5, ('A', 'C'): 6},
.....:           ('b', 'a'): {('A', 'C'): 7, ('A', 'B'): 8},
.....:           ('b', 'b'): {('A', 'D'): 9, ('A', 'B'): 10}})

Out[56]:
      a      b

```

(continues on next page)

(continued from previous page)

	b	a	c	a	b	
A	B	1.0	4.0	5.0	8.0	10.0
C		2.0	3.0	6.0	7.0	NaN
D		NaN	NaN	NaN	NaN	9.0

From a Series

The result will be a DataFrame with the same index as the input Series, and with one column whose name is the original name of the Series (only if no other column name provided).

Missing data

Much more will be said on this topic in the [Missing data](#) section. To construct a DataFrame with missing data, we use `np.nan` to represent missing values. Alternatively, you may pass a `numpy.MaskedArray` as the data argument to the DataFrame constructor, and its masked entries will be considered missing.

Alternate constructors

DataFrame.from_dict

`DataFrame.from_dict` takes a dict of dicts or a dict of array-like sequences and returns a DataFrame. It operates like the DataFrame constructor except for the `orient` parameter which is '`columns`' by default, but which can be set to '`index`' in order to use the dict keys as row labels.

```
In [57]: pd.DataFrame.from_dict(dict([('A', [1, 2, 3]), ('B', [4, 5, 6])]))
Out[57]:
   A   B
0  1  4
1  2  5
2  3  6
```

If you pass `orient='index'`, the keys will be the row labels. In this case, you can also pass the desired column names:

```
In [58]: pd.DataFrame.from_dict(dict([('A', [1, 2, 3]), ('B', [4, 5, 6])]),
.....:                      orient='index', columns=['one', 'two', 'three'])
.....:
Out[58]:
    one   two   three
A     1     2     3
B     4     5     6
```

DataFrame.from_records

`DataFrame.from_records` takes a list of tuples or an ndarray with structured dtype. It works analogously to the normal DataFrame constructor, except that the resulting DataFrame index may be a specific field of the structured dtype. For example:

```
In [59]: data
Out[59]:
array([(1, 2., b'Hello'), (2, 3., b'World')],
      dtype=[('A', '<i4'), ('B', '<f4'), ('C', 'S10')])

In [60]: pd.DataFrame.from_records(data, index='C')
Out[60]:
```

(continues on next page)

(continued from previous page)

	A	B
C		
b'Hello'	1	2.0
b'World'	2	3.0

Column selection, addition, deletion

You can treat a DataFrame semantically like a dict of like-indexed Series objects. Getting, setting, and deleting columns works with the same syntax as the analogous dict operations:

```
In [61]: df['one']
Out[61]:
a    1.0
b    2.0
c    3.0
d    NaN
Name: one, dtype: float64

In [62]: df['three'] = df['one'] * df['two']

In [63]: df['flag'] = df['one'] > 2

In [64]: df
Out[64]:
   one  two  three  flag
a  1.0  1.0    1.0  False
b  2.0  2.0    4.0  False
c  3.0  3.0    9.0   True
d  NaN  4.0    NaN  False
```

Columns can be deleted or popped like with a dict:

```
In [65]: del df['two']

In [66]: three = df.pop('three')

In [67]: df
Out[67]:
   one  flag
a  1.0  False
b  2.0  False
c  3.0   True
d  NaN  False
```

When inserting a scalar value, it will naturally be propagated to fill the column:

```
In [68]: df['foo'] = 'bar'

In [69]: df
Out[69]:
   one  flag  foo
a  1.0  False  bar
b  2.0  False  bar
c  3.0   True  bar
d  NaN  False  bar
```

When inserting a Series that does not have the same index as the DataFrame, it will be conformed to the DataFrame's index:

```
In [70]: df['one_trunc'] = df['one'] [:2]
```

```
In [71]: df
```

```
Out[71]:
```

	one	flag	foo	one_trunc
a	1.0	False	bar	1.0
b	2.0	False	bar	2.0
c	3.0	True	bar	NaN
d	NaN	False	bar	NaN

You can insert raw ndarrays but their length must match the length of the DataFrame's index.

By default, columns get inserted at the end. The `insert` function is available to insert at a particular location in the columns:

```
In [72]: df.insert(1, 'bar', df['one'])
```

```
In [73]: df
```

```
Out[73]:
```

	one	bar	flag	foo	one_trunc
a	1.0	1.0	False	bar	1.0
b	2.0	2.0	False	bar	2.0
c	3.0	3.0	True	bar	NaN
d	NaN	NaN	False	bar	NaN

Assigning new columns in method chains

Inspired by `dplyr`'s `mutate` verb, DataFrame has an `assign()` method that allows you to easily create new columns that are potentially derived from existing columns.

```
In [74]: iris = pd.read_csv('data/iris.data')
```

```
In [75]: iris.head()
```

```
Out[75]:
```

	SepalLength	SepalWidth	PetalLength	PetalWidth	Name
0	5.1	3.5	1.4	0.2	Iris-setosa
1	4.9	3.0	1.4	0.2	Iris-setosa
2	4.7	3.2	1.3	0.2	Iris-setosa
3	4.6	3.1	1.5	0.2	Iris-setosa
4	5.0	3.6	1.4	0.2	Iris-setosa

```
In [76]: (iris.assign(sepal_ratio=iris['SepalWidth'] / iris['SepalLength']))
```

```
....:     .head())
```

```
....:
```

```
Out[76]:
```

	SepalLength	SepalWidth	PetalLength	PetalWidth	Name	sepal_ratio
0	5.1	3.5	1.4	0.2	Iris-setosa	0.686275
1	4.9	3.0	1.4	0.2	Iris-setosa	0.612245
2	4.7	3.2	1.3	0.2	Iris-setosa	0.680851
3	4.6	3.1	1.5	0.2	Iris-setosa	0.673913
4	5.0	3.6	1.4	0.2	Iris-setosa	0.720000

In the example above, we inserted a precomputed value. We can also pass in a function of one argument to be evaluated on the DataFrame being assigned to.

```
In [77]: iris.assign(sepal_ratio=lambda x: (x['SepalWidth'] / x['SepalLength'])).head()
```

Out[77]:

	SepalLength	SepalWidth	PetalLength	PetalWidth	Name	sepal_ratio
0	5.1	3.5	1.4	0.2	Iris-setosa	0.686275
1	4.9	3.0	1.4	0.2	Iris-setosa	0.612245
2	4.7	3.2	1.3	0.2	Iris-setosa	0.680851
3	4.6	3.1	1.5	0.2	Iris-setosa	0.673913
4	5.0	3.6	1.4	0.2	Iris-setosa	0.720000

assign **always** returns a copy of the data, leaving the original DataFrame untouched.

Passing a callable, as opposed to an actual value to be inserted, is useful when you don't have a reference to the DataFrame at hand. This is common when using assign in a chain of operations. For example, we can limit the DataFrame to just those observations with a Sepal Length greater than 5, calculate the ratio, and plot:

```
In [78]: (iris.query('SepalLength > 5')
.....    .assign(SepalRatio=lambda x: x.SepalWidth / x.SepalLength,
.....          PetalRatio=lambda x: x.PetalWidth / x.PetalLength)
.....    .plot(kind='scatter', x='SepalRatio', y='PetalRatio'))
```

Out[78]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6da6d88d10>

Since a function is passed in, the function is computed on the DataFrame being assigned to. Importantly, this is the DataFrame that's been filtered to those rows with sepal length greater than 5. The filtering happens first, and then the

ratio calculations. This is an example where we didn't have a reference to the *filtered* DataFrame available.

The function signature for `assign` is simply `**kwargs`. The keys are the column names for the new fields, and the values are either a value to be inserted (for example, a `Series` or NumPy array), or a function of one argument to be called on the `DataFrame`. A *copy* of the original `DataFrame` is returned, with the new values inserted.

Changed in version 0.23.0.

Starting with Python 3.6 the order of `**kwargs` is preserved. This allows for *dependent* assignment, where an expression later in `**kwargs` can refer to a column created earlier in the same `assign()`.

```
In [79]: dfa = pd.DataFrame({ "A": [1, 2, 3],  
....:                 "B": [4, 5, 6]})  
....:  
  
In [80]: dfa.assign(C=lambda x: x['A'] + x['B'],  
....:           D=lambda x: x['A'] + x['C'])  
....:  
Out[80]:  
   A   B   C   D  
0  1   4   5   6  
1  2   5   7   9  
2  3   6   9  12
```

In the second expression, `x['C']` will refer to the newly created column, that's equal to `dfa['A'] + dfa['B']`.

Indexing / selection

The basics of indexing are as follows:

Operation	Syntax	Result
Select column	<code>df[col]</code>	<code>Series</code>
Select row by label	<code>df.loc[label]</code>	<code>Series</code>
Select row by integer location	<code>df.iloc[loc]</code>	<code>Series</code>
Slice rows	<code>df[5:10]</code>	<code>DataFrame</code>
Select rows by boolean vector	<code>df[bool_vec]</code>	<code>DataFrame</code>

Row selection, for example, returns a `Series` whose index is the columns of the `DataFrame`:

```
In [81]: df.loc['b']  
Out[81]:  
one      2  
bar      2  
flag    False  
foo     bar  
one_trunc  2  
Name: b, dtype: object  
  
In [82]: df.iloc[2]  
Out[82]:  
one      3  
bar      3  
flag    True  
foo     bar  
one_trunc  NaN  
Name: c, dtype: object
```

For a more exhaustive treatment of sophisticated label-based indexing and slicing, see the [section on indexing](#). We will address the fundamentals of reindexing / conforming to new sets of labels in the [section on reindexing](#).

Data alignment and arithmetic

Data alignment between DataFrame objects automatically align on **both the columns and the index (row labels)**. Again, the resulting object will have the union of the column and row labels.

```
In [83]: df = pd.DataFrame(np.random.randn(10, 4), columns=['A', 'B', 'C', 'D'])

In [84]: df2 = pd.DataFrame(np.random.randn(7, 3), columns=['A', 'B', 'C'])

In [85]: df + df2
Out[85]:
      A          B          C          D
0 -0.168746 -1.615697 -0.131165    NaN
1  0.826072  3.294430 -0.448076    NaN
2 -0.220790  0.524600  2.404133    NaN
3 -1.752193  1.781018 -0.413980    NaN
4 -2.276421 -0.998863  0.235133    NaN
5  1.052536 -0.009435 -1.125536    NaN
6 -1.147186  1.766459  1.475976    NaN
7     NaN        NaN        NaN    NaN
8     NaN        NaN        NaN    NaN
9     NaN        NaN        NaN    NaN
```

When doing an operation between DataFrame and Series, the default behavior is to align the Series **index** on the DataFrame **columns**, thus **broadcasting** row-wise. For example:

```
In [86]: df - df.iloc[0]
Out[86]:
      A          B          C          D
0  0.000000  0.000000  0.000000  0.000000
1  1.047799  2.477413  0.241231 -0.286255
2  0.446312  1.121324  2.556978 -0.063250
3  0.978704  1.255795  2.006328  0.358527

In the special case of working with time series data, if the DataFrame index contains dates, the broadcasting will be column-wise:

```
In [87]: index = pd.date_range('1/1/2000', periods=8)

In [88]: df = pd.DataFrame(np.random.randn(8, 3), index=index, columns=list('ABC'))

In [89]: df
Out[89]:
      A          B          C
2000-01-01 -1.442546 -0.543401 -2.029483
2000-01-02  0.496353 -0.567503  0.902214
2000-01-03 -0.630163 -0.775543 -0.456094
```

Warning:

```
df = df['A']
```

is now deprecated and will be removed in a future release. The preferred way to replicate this behavior is

```
df.sub(df['A'], axis=0)
```

For explicit control over the matching and broadcasting behavior, see the section on [flexible binary operations](#).

Operations with scalars are just as you would expect:

In [92]: `df * 5 + 2`

Out[92]:

B   -0.543401  -0.567503  -0.775543  -0.991869  -0.917527
C   -2.029483   0.902214  -0.456094  -0.283619   0.768100
```

DataFrame interoperability with NumPy functions

Elementwise NumPy ufuncs (log, exp, sqrt, ...) and various other NumPy functions can be used with no issues on Series and DataFrame, assuming the data within are numeric:

```
In [102]: np.exp(df)
Out[102]:
          A         B         C
2000-01-01  0.236325  0.580770  0.131403
2000-01-02  1.642720  0.566939  2.465054
2000-01-03  0.532505  0.460454  0.633754
2000-01-04  0.670306  0.370883  0.753054
2000-01-05  0.695233  0.399506  2.155667
2000-01-06  0.588755  0.411809  0.345301
2000-01-07  0.703669  1.158071  0.066597
2000-01-08  7.024162  0.552226  0.743632

In [103]: np.asarray(df)
Out[103]:
array([[-1.44254555, -0.54340106, -2.02948259],
       [ 0.49635346, -0.56750344,  0.90221383],
       [-0.63016288, -0.77554331, -0.4560937 ],
       [-0.40002061, -0.99186931, -0.28361889],
       [-0.36350785, -0.91752723,  0.76810023],
       [-0.52974562, -0.88719558, -1.06333974],
       [-0.3514479 ,  0.14675546, -2.70909549],
       [ 1.94935594, -0.59379705, -0.29620889]])
```

DataFrame is not intended to be a drop-in replacement for ndarray as its indexing semantics and data model are quite different in places from an n-dimensional array.

Series implements `__array_ufunc__`, which allows it to work with NumPy's universal functions.

The ufunc is applied to the underlying array in a Series.

```
In [104]: ser = pd.Series([1, 2, 3, 4])

In [105]: np.exp(ser)
Out[105]:
0    2.718282
1    7.389056
2   20.085537
3   54.598150
dtype: float64
```

Changed in version 0.25.0: When multiple Series are passed to a ufunc, they are aligned before performing the operation.

Like other parts of the library, pandas will automatically align labeled inputs as part of a ufunc with multiple inputs. For example, using numpy.remainder() on two Series with differently ordered labels will align before the operation.

```
In [106]: ser1 = pd.Series([1, 2, 3], index=['a', 'b', 'c'])

In [107]: ser2 = pd.Series([1, 3, 5], index=['b', 'a', 'c'])

In [108]: ser1
Out[108]:
a    1
b    2
c    3
dtype: int64

In [109]: ser2
Out[109]:
b    1
a    3
c    5
dtype: int64

In [110]: np.remainder(ser1, ser2)
Out[110]:
a    1
b    0
c    3
dtype: int64
```

As usual, the union of the two indices is taken, and non-overlapping values are filled with missing values.

```
In [111]: ser3 = pd.Series([2, 4, 6], index=['b', 'c', 'd'])

In [112]: ser3
Out[112]:
b    2
c    4
d    6
dtype: int64

In [113]: np.remainder(ser1, ser3)
Out[113]:
a    NaN
```

(continues on next page)

(continued from previous page)

```
b    0.0
c    3.0
d    NaN
dtype: float64
```

When a binary ufunc is applied to a `Series` and `Index`, the `Series` implementation takes precedence and a `Series` is returned.

```
In [114]: ser = pd.Series([1, 2, 3])

In [115]: idx = pd.Index([4, 5, 6])

In [116]: np.maximum(ser, idx)
Out[116]:
0    4
1    5
2    6
dtype: int64
```

NumPy ufuncs are safe to apply to `Series` backed by non-ndarray arrays, for example `arrays.SparseArray` (see [Sparse calculation](#)). If possible, the ufunc is applied without converting the underlying data to an ndarray.

Console display

Very large DataFrames will be truncated to display them in the console. You can also get a summary using `info()`. (Here I am reading a CSV version of the **baseball** dataset from the **plyr** R package):

```
In [117]: baseball = pd.read_csv('data/baseball.csv')

In [118]: print(baseball)
      id   player  year  stint  team  lg  g  ab  r  h  X2b  X3b  hr  rbi  sb

Wide DataFrames will be printed across multiple rows by default:

```
In [121]: pd.DataFrame(np.random.randn(3, 12))
Out[121]:
          0         1         2         3         4         5         6         7
     8 -0.912416 -0.249441 -0.483077 -0.712581  1.530328 -0.643267 -1.783790 -0.666507 -0.
    9  0.213889 -2.258218 -0.598566
```

(continues on next page)

(continued from previous page)

```
1 -0.562467  0.837983  0.205768  1.531142  0.058159 -0.029142  0.153631  0.304859 -0.  
↪359520  0.979755  1.190174 -0.259286  
2 -0.500779  0.967641 -0.869845  0.703079 -0.457970  1.084412  1.589819 -1.386887 -0.  
↪308542 -0.017896 -0.542891  1.681400
```

You can change how much to print on a single row by setting the `display.width` option:

```
In [122]: pd.set_option('display.width', 40) # default is 80  
  
In [123]: pd.DataFrame(np.random.randn(3, 12))  
Out[123]:  
          0         1         2         3         4         5         6         7         8

↪745255  0.036093  2.628470  0.713070
```

You can adjust the max width of the individual columns by setting `display.max_colwidth`

```
In [124]: datafile = {'filename': ['filename_01', 'filename_02'],  
.....:                 'path': ["media/user_name/storage/folder_01/filename_01",  
.....:                               "media/user_name/storage/folder_02/filename_02"]}  
.....:  
  
In [125]: pd.set_option('display.max_colwidth', 30)  
  
In [126]: pd.DataFrame(datafile)  
Out[126]:  
      filename                      path  
0  filename_01  media/user_name/storage/fo...  
1  filename_02  media/user_name/storage/fo...  
  
In [127]: pd.set_option('display.max_colwidth', 100)  
  
In [128]: pd.DataFrame(datafile)  
Out[128]:  
      filename                      path  
0  filename_01  media/user_name/storage/folder_01/filename_01  
1  filename_02  media/user_name/storage/folder_02/filename_02
```

You can also disable this feature via the `expand_frame_repr` option. This will print the table in one block.

DataFrame column attribute access and IPython completion

If a DataFrame column label is a valid Python variable name, the column can be accessed like an attribute:

```
In [129]: df = pd.DataFrame({'foo1': np.random.randn(5),  
.....:                   'foo2': np.random.randn(5)})  
.....:  
  
In [130]: df  
Out[130]:
```

(continues on next page)

(continued from previous page)

```

    foo1      foo2
0 -1.293036 -2.352684
1  1.568678  0.037267
2 -0.562916  0.676653
3  1.212760 -0.126038
4  1.446673  0.086856

In [131]: df.foo1
Out[131]:
0     -1.293036
1      1.568678
2     -0.562916
3      1.212760
4      1.446673
Name: foo1, dtype: float64

```

The columns are also connected to the IPython completion mechanism so they can be tab-completed:

```

In [5]: df.fo<TAB>  # noqa: E225, E999
df.foo1  df.foo2

```

2.6 Comparison with other tools

{}{{ header }}

2.6.1 Comparison with R / R libraries

Since pandas aims to provide a lot of the data manipulation and analysis functionality that people use R for, this page was started to provide a more detailed look at the R language and its many third party libraries as they relate to pandas. In comparisons with R and CRAN libraries, we care about the following things:

- **Functionality / flexibility:** what can/cannot be done with each tool
- **Performance:** how fast are operations. Hard numbers/benchmarks are preferable
- **Ease-of-use:** Is one tool easier/harder to use (you may have to be the judge of this, given side-by-side code comparisons)

This page is also here to offer a bit of a translation guide for users of these R packages.

For transfer of DataFrame objects from pandas to R, one option is to use HDF5 files, see [External compatibility](#) for an example.

Quick reference

We'll start off with a quick reference guide pairing some common R operations using `dplyr` with pandas equivalents.

Querying, filtering, sampling

R	pandas
<code>dim(df)</code>	<code>df.shape</code>
<code>head(df)</code>	<code>df.head()</code>
<code>slice(df, 1:10)</code>	<code>df.iloc[:9]</code>
<code>filter(df, col1 == 1, col2 == 1)</code>	<code>df.query('col1 == 1 & col2 == 1')</code>
<code>df[df\$col1 == 1 & df\$col2 == 1,]</code>	<code>df[(df.col1 == 1) & (df.col2 == 1)]</code>
<code>select(df, col1, col2)</code>	<code>df[['col1', 'col2']]</code>
<code>select(df, col1:col3)</code>	<code>df.loc[:, 'col1':'col3']</code>
<code>select(df, -(col1:col3))</code>	<code>df.drop(cols_to_drop, axis=1) but see¹</code>
<code>distinct(select(df, col1))</code>	<code>df[['col1']].drop_duplicates()</code>
<code>distinct(select(df, col1, col2))</code>	<code>df[['col1', 'col2']].drop_duplicates()</code>
<code>sample_n(df, 10)</code>	<code>df.sample(n=10)</code>
<code>sample_frac(df, 0.01)</code>	<code>df.sample(frac=0.01)</code>

Sorting

R	pandas
<code>arrange(df, col1, col2)</code>	<code>df.sort_values(['col1', 'col2'])</code>
<code>arrange(df, desc(col1))</code>	<code>df.sort_values('col1', ascending=False)</code>

Transforming

R	pandas
<code>select(df, col_one = col1)</code>	<code>df.rename(columns={'col1': 'col_one'})['col_one']</code>
<code>rename(df, col_one = col1)</code>	<code>df.rename(columns={'col1': 'col_one'})</code>
<code>mutate(df, c=a-b)</code>	<code>df.assign(c=df['a']-df['b'])</code>

¹ R's shorthand for a subrange of columns (`select(df, col1:col3)`) can be approached cleanly in pandas, if you have the list of columns, for example `df[cols[1:3]]` or `df.drop(cols[1:3])`, but doing this by column name is a bit messy.

Grouping and summarizing

R	pandas
summary(df)	df.describe()
gdf <- group_by(df, col1)	gdf = df.groupby('col1')
summarise(gdf, avg=mean(col1, na.rm=TRUE))	df.groupby('col1').agg({'col1': 'mean'})
summarise(gdf, total=sum(col1))	df.groupby('col1').sum()

Base R

Slicing with R's c

R makes it easy to access `data.frame` columns by name

```
df <- data.frame(a=rnorm(5), b=rnorm(5), c=rnorm(5), d=rnorm(5), e=rnorm(5))
df[, c("a", "c", "e")]
```

or by integer location

```
df <- data.frame(matrix(rnorm(1000), ncol=100))
df[, c(1:10, 25:30, 40, 50:100)]
```

Selecting multiple columns by name in pandas is straightforward

```
In [1]: df = pd.DataFrame(np.random.randn(10, 3), columns=list('abc'))

In [2]: df[['a', 'c']]
Out[2]:
      a      c
0  0.340101  0.867062
1  1.058080  0.339523
2 -1.593996 -0.470527
3  0.604893 -0.281128
4 -0.285603  2.115705
5 -0.445862 -0.005865
6  2.770876  1.185076
7 -1.356648  0.239418
8 -0.751105 -1.335485
9 -1.083317 -0.103423

In [3]: df.loc[:, ['a', 'c']]
Out[3]:
      a      c
0  0.340101  0.867062
1  1.058080  0.339523
2 -1.593996 -0.470527
3  0.604893 -0.281128
4 -0.285603  2.115705
5 -0.445862 -0.005865
6  2.770876  1.185076
7 -1.356648  0.239418
8 -0.751105 -1.335485
9 -1.083317 -0.103423
```

Selecting multiple noncontiguous columns by integer location can be achieved with a combination of the `iloc` indexer attribute and `numpy.r_`.

```
In [4]: named = list('abcdefg')

In [5]: n = 30

In [6]: columns = named + np.arange(len(named), n).tolist()

In [7]: df = pd.DataFrame(np.random.randn(n, n), columns=columns)

In [8]: df.iloc[:, np.r_[:10, 24:30]]
Out[8]:
```

	a	b	c	d	e	f	g	7

aggregate

In R you may want to split data into subsets and compute the mean for each. Using a data.frame called `df` and splitting it into groups `by1` and `by2`:

```
df <- data.frame(
  v1 = c(1, 3, 5, 7, 8, 3, 5, NA, 4, 5, 7, 9),
  v2 = c(11, 33, 55, 77, 88, 33, 55, NA, 44, 55, 77, 99),
  by1 = c("red", "blue", 1, 2, NA, "big", 1, 2, "red", 1, NA, 12),
  by2 = c("wet", "dry", 99, 95, NA, "damp", 95, 99, "red", 99, NA, NA))
aggregate(x=df[, c("v1", "v2")], by=list(mydf2$by1, mydf2$by2), FUN = mean)
```

The `groupby()` method is similar to base R `aggregate` function.

```
In [9]: df = pd.DataFrame(
....:     {'v1': [1, 3, 5, 7, 8, 3, 5, np.nan, 4, 5, 7, 9],
....:      'v2': [11, 33, 55, 77, 88, 33, 55, np.nan, 44, 55, 77, 99],
....:      'by1': ["red", "blue", 1, 2, np.nan, "big", 1, 2, "red", 1, np.nan, 12],
....:      'by2': ["wet", "dry", 99, 95, np.nan, "damp", 95, 99, "red", 99, np.nan,
....:              np.nan]})

In [10]: g = df.groupby(['by1', 'by2'])

In [11]: g[['v1', 'v2']].mean()
Out[11]:
          v1      v2
by1   by2
1    95    5.0  55.0
      99    5.0  55.0
2    95    7.0  77.0
      99    NaN  NaN
big  damp   3.0  33.0
blue dry    3.0  33.0
red  red    4.0  44.0
wet   wet   1.0  11.0
```

For more details and examples see [the `groupby` documentation](#).

match / %in%

A common way to select data in R is using `%in%` which is defined using the function `match`. The operator `%in%` is used to return a logical vector indicating if there is a match or not:

```
s <- 0:4
s %in% c(2, 4)
```

The `isin()` method is similar to R `%in%` operator:

```
In [12]: s = pd.Series(np.arange(5), dtype=np.float32)

In [13]: s.isin([2, 4])
Out[13]:
0    False
1    False
2     True
3    False
4     True
dtype: bool
```

The `match` function returns a vector of the positions of matches of its first argument in its second:

```
s <- 0:4
match(s, c(2, 4))
```

For more details and examples see *the reshaping documentation*.

tapply

`tapply` is similar to `aggregate`, but data can be in a ragged array, since the subclass sizes are possibly irregular. Using a `data.frame` called `baseball`, and retrieving information based on the array `team`:

```
baseball <-
  data.frame(team = gl(5, 5,
                      labels = paste("Team", LETTERS[1:5])),
             player = sample(letters, 25),
             batting.average = runif(25, .200, .400))

tapply(baseball$batting.average, baseball.example$team,
       max)
```

In pandas we may use `pivot_table()` method to handle this:

```
In [14]: import random

In [15]: import string

In [16]: baseball = pd.DataFrame(
.....      {'team': ["team %d" % (x + 1) for x in range(5)] * 5,
.....       'player': random.sample(list(string.ascii_lowercase), 25),
.....       'batting avg': np.random.uniform(.200, .400, 25)})
..... 

In [17]: baseball.pivot_table(values='batting avg', columns='team', aggfunc=np.max)
Out[17]:
```

(continues on next page)

(continued from previous page)

team	team 1	team 2	team 3	team 4	team 5
batting avg	0.316228	0.297656	0.380969	0.396857	0.374905

For more details and examples see [the reshaping documentation](#).

subset

The `query()` method is similar to the base R `subset` function. In R you might want to get the rows of a `data.frame` where one column's values are less than another column's values:

```
df <- data.frame(a=rnorm(10), b=rnorm(10))
subset(df, a <= b)
df[df$a <= df$b,] # note the comma
```

In pandas, there are a few ways to perform subsetting. You can use `query()` or pass an expression as if it were an index/slice as well as standard boolean indexing:

```
In [18]: df = pd.DataFrame({'a': np.random.randn(10), 'b': np.random.randn(10)})
```

```
In [19]: df.query('a <= b')
```

```
Out[19]:
```

	a	b
3	-0.301825	1.247946
4	0.047138	2.075146
6	0.065820	1.073036
8	-1.078313	-0.464384

```
In [20]: df[df['a'] <= df['b']]
```

```
Out[20]:
```

	a	b
3	-0.301825	1.247946
4	0.047138	2.075146
6	0.065820	1.073036
8	-1.078313	-0.464384

```
In [21]: df.loc[df['a'] <= df['b']]
```

```
Out[21]:
```

	a	b
3	-0.301825	1.247946
4	0.047138	2.075146
6	0.065820	1.073036
8	-1.078313	-0.464384

For more details and examples see [the query documentation](#).

with

An expression using a data.frame called `df` in R with the columns `a` and `b` would be evaluated using `with` like so:

```
df <- data.frame(a=rnorm(10), b=rnorm(10))
with(df, a + b)
df$a + df$b # same as the previous expression
```

In pandas the equivalent expression, using the `eval()` method, would be:

```
In [22]: df = pd.DataFrame({'a': np.random.randn(10), 'b': np.random.randn(10)})
```

```
In [23]: df.eval('a + b')
```

```
Out[23]:
```

```
0    -1.495506
1    -0.434193
2    -0.794116
3    -0.729720
4    -0.486142
5     1.553739
6     0.839767
7    -0.058974
8     2.637971
9     1.317973
dtype: float64
```

```
In [24]: df['a'] + df['b'] # same as the previous expression
```

```
Out[24]:
```

```
0    -1.495506
1    -0.434193
2    -0.794116
3    -0.729720
4    -0.486142
5     1.553739
6     0.839767
7    -0.058974
8     2.637971
9     1.317973
dtype: float64
```

In certain cases `eval()` will be much faster than evaluation in pure Python. For more details and examples see [the eval documentation](#).

plyr

`plyr` is an R library for the split-apply-combine strategy for data analysis. The functions revolve around three data structures in R, `a` for arrays, `l` for lists, and `d` for `data.frame`. The table below shows how these data structures could be mapped in Python.

R	Python
array	list
lists	dictionary or list of objects
data.frame	dataframe

ddply

An expression using a data.frame called `df` in R where you want to summarize `x` by month:

```
require(plyr)
df <- data.frame(
  x = runif(120, 1, 168),
  y = runif(120, 7, 334),
  z = runif(120, 1.7, 20.7),
  month = rep(c(5,6,7,8),30),
  week = sample(1:4, 120, TRUE)
)

ddply(df, .(month, week), summarize,
      mean = round(mean(x), 2),
      sd = round(sd(x), 2))
```

In pandas the equivalent expression, using the `groupby()` method, would be:

```
In [25]: df = pd.DataFrame({'x': np.random.uniform(1., 168., 120),
....:                      'y': np.random.uniform(7., 334., 120),
....:                      'z': np.random.uniform(1.7, 20.7, 120),
....:                      'month': [5, 6, 7, 8] * 30,
....:                      'week': np.random.randint(1, 4, 120)})

In [26]: grouped = df.groupby(['month', 'week'])

In [27]: grouped['x'].agg([np.mean, np.std])
Out[27]:
          mean      std
month week
5      1    80.480045  48.797524
       2    78.145053  68.252324
       3    67.236816  53.786204
6      1   104.644894  32.989411
       2    69.334700  39.674412
       3    94.475329  66.308245
7      1    83.826612  59.727376
       2   117.447282  41.253258
       3    72.535571  40.045123
8      1    61.130522  53.704837
       2    74.439580  59.676455
       3   103.433367  31.808549
```

For more details and examples see [the groupby documentation](#).

reshape / reshape2

melt.array

An expression using a 3 dimensional array called `a` in R where you want to melt it into a data.frame:

```
a <- array(c(1:23, NA), c(2,3,4))
data.frame(melt(a))
```

In Python, since `a` is a list, you can simply use list comprehension.

```
In [28]: a = np.array(list(range(1, 24)) + [np.NAN]).reshape(2, 3, 4)

In [29]: pd.DataFrame([tuple(list(x) + [val]) for x, val in np.ndenumerate(a)])
Out[29]:
   0   1   2   3
0   0   0   0   1.0
1   0   0   1   2.0
2   0   0   2   3.0
3   0   0   3   4.0
4   0   1   0   5.0
5   0   1   1   6.0
6   0   1   2   7.0
7   0   1   3   8.0
8   0   2   0   9.0
9   0   2   1  10.0
10  0   2   2  11.0
11  0   2   3  12.0
12  1   0   0  13.0
13  1   0   1  14.0
14  1   0   2  15.0
15  1   0   3  16.0
16  1   1   0  17.0
17  1   1   1  18.0
18  1   1   2  19.0
19  1   1   3  20.0
20  1   2   0  21.0
21  1   2   1  22.0
22  1   2   2  23.0
23  1   2   3    NaN
```

melt.list

An expression using a list called `a` in R where you want to melt it into a data.frame:

```
a <- as.list(c(1:4, NA))
data.frame(melt(a))
```

In Python, this list would be a list of tuples, so `DataFrame()` method would convert it to a dataframe as required.

```
In [30]: a = list(enumerate(list(range(1, 5)) + [np.NAN]))
In [31]: pd.DataFrame(a)
Out[31]:
   0   1
```

(continues on next page)

(continued from previous page)

0	0	1.0
1	1	2.0
2	2	3.0
3	3	4.0
4	4	NaN

For more details and examples see [the *Into to Data Structures* documentation](#).

melt.data.frame

An expression using a data.frame called `cheese` in R where you want to reshape the data.frame:

```
cheese <- data.frame(
  first = c('John', 'Mary'),
  last = c('Doe', 'Bo'),
  height = c(5.5, 6.0),
  weight = c(130, 150)
)
melt(cheese, id=c("first", "last"))
```

In Python, the `melt()` method is the R equivalent:

```
In [32]: cheese = pd.DataFrame({'first': ['John', 'Mary'],
.....:                               'last': ['Doe', 'Bo'],
.....:                               'height': [5.5, 6.0],
.....:                               'weight': [130, 150]})

In [33]: pd.melt(cheese, id_vars=['first', 'last'])
Out[33]:
   first last variable  value
0   John   Doe    height    5.5
1   Mary   Bo    height    6.0
2   John   Doe    weight  130.0
3   Mary   Bo    weight  150.0

In [34]: cheese.set_index(['first', 'last']).stack()  # alternative way
Out[34]:
first  last
John    Doe    height    5.5
          weight  130.0
Mary    Bo     height    6.0
          weight  150.0
dtype: float64
```

For more details and examples see [the *reshaping* documentation](#).

cast

In R `acast` is an expression using a `data.frame` called `df` in R to cast into a higher dimensional array:

```
df <- data.frame(
  x = runif(12, 1, 168),
  y = runif(12, 7, 334),
  z = runif(12, 1.7, 20.7),
  month = rep(c(5,6,7),4),
  week = rep(c(1,2), 6)
)

mdf <- melt(df, id=c("month", "week"))
acast(mdf, week ~ month ~ variable, mean)
```

In Python the best way is to make use of `pivot_table()`:

```
In [35]: df = pd.DataFrame({'x': np.random.uniform(1., 168., 12),
....:                     'y': np.random.uniform(7., 334., 12),
....:                     'z': np.random.uniform(1.7, 20.7, 12),
....:                     'month': [5, 6, 7] * 4,
....:                     'week': [1, 2] * 6})
....:

In [36]: mdf = pd.melt(df, id_vars=['month', 'week'])

In [37]: pd.pivot_table(mdf, values='value', index=['variable', 'week'],
....:                     columns=['month'], aggfunc=np.mean)
....:

Out[37]:
month      5      6      7
variable week
x    1    44.868293  26.200107  101.913323
      2    93.309785  146.513765  128.990227
y    1    228.502341  127.917337  123.198427
      2    161.802639  221.438748   83.058118
z    1     9.519740    9.177787   12.438793
      2    13.376850    8.544512   5.999564
```

Similarly for `dcast` which uses a `data.frame` called `df` in R to aggregate information based on `Animal` and `FeedType`:

```
df <- data.frame(
  Animal = c('Animal1', 'Animal2', 'Animal3', 'Animal2', 'Animal1',
             'Animal2', 'Animal3'),
  FeedType = c('A', 'B', 'A', 'A', 'B', 'B', 'A'),
  Amount = c(10, 7, 4, 2, 5, 6, 2)
)

dcast(df, Animal ~ FeedType, sum, fill=NaN)
# Alternative method using base R
with(df, tapply(Amount, list(Animal, FeedType), sum))
```

Python can approach this in two different ways. Firstly, similar to above using `pivot_table()`:

```
In [38]: df = pd.DataFrame({
....:     'Animal': ['Animal1', 'Animal2', 'Animal3', 'Animal2', 'Animal1',
```

(continues on next page)

(continued from previous page)

```

....:             'Animal2', 'Animal3'],
....:             'FeedType': ['A', 'B', 'A', 'A', 'B', 'B', 'A'],
....:             'Amount': [10, 7, 4, 2, 5, 6, 2],
....:         })
....:

In [39]: df.pivot_table(values='Amount', index='Animal', columns='FeedType',
....:                      aggfunc='sum')
....:

Out[39]:
FeedType      A      B
Animal
Animal1     10.0    5.0
Animal2      2.0   13.0
Animal3      6.0    NaN

```

The second approach is to use the `groupby()` method:

```

In [40]: df.groupby(['Animal', 'FeedType'])['Amount'].sum()
Out[40]:
Animal  FeedType
Animal1  A          10
           B          5
Animal2  A          2
           B         13
Animal3  A          6
Name: Amount, dtype: int64

```

For more details and examples see [the reshaping documentation](#) or [the groupby documentation](#).

factor

pandas has a data type for categorical data.

```

cut(c(1,2,3,4,5,6), 3)
factor(c(1,2,3,2,2,3))

```

In pandas this is accomplished with `pd.cut` and `astype("category")`:

```

In [41]: pd.cut(pd.Series([1, 2, 3, 4, 5, 6]), 3)
Out[41]:
0      (0.995, 2.667]
1      (0.995, 2.667]
2      (2.667, 4.333]
3      (2.667, 4.333]
4      (4.333, 6.0]
5      (4.333, 6.0]
dtype: category
Categories (3, interval[float64]): [(0.995, 2.667] < (2.667, 4.333] < (4.333, 6.0]]

In [42]: pd.Series([1, 2, 3, 2, 2, 3]).astype("category")
Out[42]:
0    1
1    2
2    3

```

(continues on next page)

(continued from previous page)

```
3    2
4    2
5    3
dtype: category
Categories (3, int64): [1, 2, 3]
```

For more details and examples see [categorical introduction](#) and the [API documentation](#). There is also a documentation regarding the [differences to R's factor](#). {{ header }}

2.6.2 Comparison with SQL

Since many potential pandas users have some familiarity with [SQL](#), this page is meant to provide some examples of how various SQL operations would be performed using pandas.

If you're new to pandas, you might want to first read through [10 Minutes to pandas](#) to familiarize yourself with the library.

As is customary, we import pandas and NumPy as follows:

```
In [1]: import pandas as pd

In [2]: import numpy as np
```

Most of the examples will utilize the `tips` dataset found within pandas tests. We'll read the data into a DataFrame called `tips` and assume we have a database table of the same name and structure.

```
In [3]: url = ('https://raw.github.com/pandas-dev'
...:           '/pandas/master/pandas/tests/data/tips.csv')
...:

In [4]: tips = pd.read_csv(url)

In [5]: tips.head()
Out[5]:
   total_bill  tip     sex smoker  day    time  size
0      16.99  1.01  Female     No  Sun  Dinner     2
1      10.34  1.66    Male     No  Sun  Dinner     3
2      21.01  3.50    Male     No  Sun  Dinner     3
3      23.68  3.31    Male     No  Sun  Dinner     2
4      24.59  3.61  Female     No  Sun  Dinner     4
```

SELECT

In SQL, selection is done using a comma-separated list of columns you'd like to select (or a `*` to select all columns):

```
SELECT total_bill, tip, smoker, time
FROM tips
LIMIT 5;
```

With pandas, column selection is done by passing a list of column names to your DataFrame:

```
In [6]: tips[['total_bill', 'tip', 'smoker', 'time']].head(5)
Out[6]:
   total_bill  tip smoker    time
```

(continues on next page)

(continued from previous page)

0	16.99	1.01	No	Dinner
1	10.34	1.66	No	Dinner
2	21.01	3.50	No	Dinner
3	23.68	3.31	No	Dinner
4	24.59	3.61	No	Dinner

Calling the DataFrame without the list of column names would display all columns (akin to SQL's *).

In SQL, you can add a calculated column:

```
SELECT *, tip/total_bill as tip_rate
FROM tips
LIMIT 5;
```

With pandas, you can use the `DataFrame.assign()` method of a DataFrame to append a new column:

```
In [7]: tips.assign(tip_rate=tips['tip'] / tips['total_bill']).head(5)
Out[7]:
   total_bill  tip      sex smoker  day    time  size  tip_rate
0      16.99  1.01  Female     No  Sun  Dinner    2  0.059447
1      10.34  1.66    Male     No  Sun  Dinner    3  0.160542
2      21.01  3.50    Male     No  Sun  Dinner    3  0.166587
3      23.68  3.31    Male     No  Sun  Dinner    2  0.139780
4      24.59  3.61  Female     No  Sun  Dinner    4  0.146808
```

WHERE

Filtering in SQL is done via a WHERE clause.

```
SELECT *
FROM tips
WHERE time = 'Dinner'
LIMIT 5;
```

DataFrames can be filtered in multiple ways; the most intuitive of which is using boolean indexing.

```
In [8]: tips[tips['time'] == 'Dinner'].head(5)
Out[8]:
   total_bill  tip      sex smoker  day    time  size
0      16.99  1.01  Female     No  Sun  Dinner    2
1      10.34  1.66    Male     No  Sun  Dinner    3
2      21.01  3.50    Male     No  Sun  Dinner    3
3      23.68  3.31    Male     No  Sun  Dinner    2
4      24.59  3.61  Female     No  Sun  Dinner    4
```

The above statement is simply passing a Series of True/False objects to the DataFrame, returning all rows with True.

```
In [9]: is_dinner = tips['time'] == 'Dinner'

In [10]: is_dinner.value_counts()
Out[10]:
True      176
False      68
Name: time, dtype: int64
```

(continues on next page)

(continued from previous page)

```
In [11]: tips[is_dinner].head(5)
Out[11]:
   total_bill  tip    sex smoker  day    time  size
0      16.99  1.01  Female     No  Sun  Dinner     2
1      10.34  1.66    Male     No  Sun  Dinner     3
2      21.01  3.50    Male     No  Sun  Dinner     3
3      23.68  3.31    Male     No  Sun  Dinner     2
4      24.59  3.61  Female     No  Sun  Dinner     4
```

Just like SQL's OR and AND, multiple conditions can be passed to a DataFrame using | (OR) and & (AND).

```
-- tips of more than $5.00 at Dinner meals
SELECT *
FROM tips
WHERE time = 'Dinner' AND tip > 5.00;
```

```
# tips of more than $5.00 at Dinner meals
In [12]: tips[(tips['time'] == 'Dinner') & (tips['tip'] > 5.00)]
Out[12]:
   total_bill  tip    sex smoker  day    time  size
23      39.42  7.58    Male     No  Sat  Dinner     4
44      30.40  5.60    Male     No  Sun  Dinner     4
47      32.40  6.00    Male     No  Sun  Dinner     4
52      34.81  5.20  Female     No  Sun  Dinner     4
59      48.27  6.73    Male     No  Sat  Dinner     4
116     29.93  5.07    Male     No  Sun  Dinner     4
155     29.85  5.14  Female     No  Sun  Dinner     5
170     50.81 10.00    Male    Yes  Sat  Dinner     3
172      7.25  5.15    Male    Yes  Sun  Dinner     2
181     23.33  5.65    Male    Yes  Sun  Dinner     2
183     23.17  6.50    Male    Yes  Sun  Dinner     4
211     25.89  5.16    Male    Yes  Sat  Dinner     4
212     48.33  9.00    Male     No  Sat  Dinner     4
214     28.17  6.50  Female    Yes  Sat  Dinner     3
239     29.03  5.92    Male     No  Sat  Dinner     3
```

```
-- tips by parties of at least 5 diners OR bill total was more than $45
SELECT *
FROM tips
WHERE size >= 5 OR total_bill > 45;
```

```
# tips by parties of at least 5 diners OR bill total was more than $45
In [13]: tips[(tips['size'] >= 5) | (tips['total_bill'] > 45)]
Out[13]:
   total_bill  tip    sex smoker  day    time  size
59      48.27  6.73    Male     No  Sat  Dinner     4
125     29.80  4.20  Female     No  Thur  Lunch     6
141     34.30  6.70    Male     No  Thur  Lunch     6
142     41.19  5.00    Male     No  Thur  Lunch     5
143     27.05  5.00  Female     No  Thur  Lunch     6
155     29.85  5.14  Female     No  Sun  Dinner     5
156     48.17  5.00    Male     No  Sun  Dinner     6
170     50.81 10.00    Male    Yes  Sat  Dinner     3
182     45.35  3.50    Male    Yes  Sun  Dinner     3
```

(continues on next page)

(continued from previous page)

185	20.69	5.00	Male	No	Sun	Dinner	5
187	30.46	2.00	Male	Yes	Sun	Dinner	5
212	48.33	9.00	Male	No	Sat	Dinner	4
216	28.15	3.00	Male	Yes	Sat	Dinner	5

NULL checking is done using the `notna()` and `isna()` methods.

```
In [14]: frame = pd.DataFrame({'col1': ['A', 'B', np.nan, 'C', 'D'],
....:                           'col2': ['F', np.nan, 'G', 'H', 'I']})

In [15]: frame
Out[15]:
   col1  col2
0     A    F
1     B  NaN
2    NaN    G
3     C    H
4     D    I
```

Assume we have a table of the same structure as our DataFrame above. We can see only the records where `col2` IS NULL with the following query:

```
SELECT *
FROM frame
WHERE col2 IS NULL;
```

```
In [16]: frame[frame['col2'].isna()]
Out[16]:
   col1  col2
1     B  NaN
```

Getting items where `col1` IS NOT NULL can be done with `notna()`.

```
SELECT *
FROM frame
WHERE col1 IS NOT NULL;
```

```
In [17]: frame[frame['col1'].notna()]
Out[17]:
   col1  col2
0     A    F
1     B  NaN
3     C    H
4     D    I
```

GROUP BY

In pandas, SQL's GROUP BY operations are performed using the similarly named `groupby()` method. `groupby()` typically refers to a process where we'd like to split a dataset into groups, apply some function (typically aggregation), and then combine the groups together.

A common SQL operation would be getting the count of records in each group throughout a dataset. For instance, a query getting us the number of tips left by sex:

```
SELECT sex, count(*)
FROM tips
GROUP BY sex;
/*
Female      87
Male       157
*/
```

The pandas equivalent would be:

```
In [18]: tips.groupby('sex').size()
Out[18]:
sex
Female      87
Male       157
dtype: int64
```

Notice that in the pandas code we used `size()` and not `count()`. This is because `count()` applies the function to each column, returning the number of not null records within each.

```
In [19]: tips.groupby('sex').count()
Out[19]:
   total_bill  tip  smoker  day  time  size
sex
Female        87    87      87    87    87    87
Male         157   157     157   157   157   157
```

Alternatively, we could have applied the `count()` method to an individual column:

```
In [20]: tips.groupby('sex')[['total_bill']].count()
Out[20]:
sex
Female      87
Male       157
Name: total_bill, dtype: int64
```

Multiple functions can also be applied at once. For instance, say we'd like to see how tip amount differs by day of the week - `agg()` allows you to pass a dictionary to your grouped DataFrame, indicating which functions to apply to specific columns.

```
SELECT day, AVG(tip), COUNT(*)
FROM tips
GROUP BY day;
/*
Fri    2.734737  19
Sat    2.993103  87
Sun    3.255132  76
Thur   2.771452  62
*/
```

```
In [21]: tips.groupby('day').agg({'tip': np.mean, 'day': np.size})
Out[21]:
      tip  day
day
Fri    2.734737  19
Sat    2.993103  87
Sun    3.255132  76
Thur   2.771452  62
```

Grouping by more than one column is done by passing a list of columns to the `groupby()` method.

```
SELECT smoker, day, COUNT(*), AVG(tip)
FROM tips
GROUP BY smoker, day;
/*
smoker day
No    Fri      4  2.812500
      Sat     45  3.102889
      Sun     57  3.167895
      Thur    45  2.673778
Yes   Fri      15 2.714000
      Sat     42  2.875476
      Sun     19  3.516842
      Thur    17  3.030000
*/
```

```
In [22]: tips.groupby(['smoker', 'day']).agg({'tip': [np.size, np.mean]})
Out[22]:
      tip
      size      mean
smoker day
No    Fri    4.0  2.812500
      Sat   45.0  3.102889
      Sun   57.0  3.167895
      Thur  45.0  2.673778
Yes   Fri   15.0 2.714000
      Sat   42.0  2.875476
      Sun   19.0  3.516842
      Thur  17.0  3.030000
```

JOIN

JOINS can be performed with `join()` or `merge()`. By default, `join()` will join the DataFrames on their indices. Each method has parameters allowing you to specify the type of join to perform (LEFT, RIGHT, INNER, FULL) or the columns to join on (column names or indices).

```
In [23]: df1 = pd.DataFrame({'key': ['A', 'B', 'C', 'D'],
                           ....:                 'value': np.random.randn(4)})
....:

In [24]: df2 = pd.DataFrame({'key': ['B', 'D', 'D', 'E'],
                           ....:                 'value': np.random.randn(4)})
....:
```

Assume we have two database tables of the same name and structure as our DataFrames.

Now let's go over the various types of JOINS.

INNER JOIN

```
SELECT *
FROM df1
INNER JOIN df2
    ON df1.key = df2.key;
```

```
# merge performs an INNER JOIN by default
In [25]: pd.merge(df1, df2, on='key')
Out[25]:
   key    value_x    value_y
0    B -1.491089  0.499188
1    D  0.242591  0.553885
2    D  0.242591 -1.179391
```

`merge()` also offers parameters for cases when you'd like to join one DataFrame's column with another DataFrame's index.

```
In [26]: indexed_df2 = df2.set_index('key')

In [27]: pd.merge(df1, indexed_df2, left_on='key', right_index=True)
Out[27]:
   key    value_x    value_y
1    B -1.491089  0.499188
3    D  0.242591  0.553885
3    D  0.242591 -1.179391
```

LEFT OUTER JOIN

```
-- show all records from df1
SELECT *
FROM df1
LEFT OUTER JOIN df2
    ON df1.key = df2.key;
```

```
# show all records from df1
In [28]: pd.merge(df1, df2, on='key', how='left')
Out[28]:
   key    value_x    value_y
0    A -0.061166        NaN
1    B -1.491089  0.499188
2    C  0.612852        NaN
3    D  0.242591  0.553885
4    D  0.242591 -1.179391
```

RIGHT JOIN

```
-- show all records from df2
SELECT *
FROM df1
RIGHT OUTER JOIN df2
ON df1.key = df2.key;
```

```
# show all records from df2
In [29]: pd.merge(df1, df2, on='key', how='right')
Out[29]:
  key    value_x    value_y
0   B -1.491089  0.499188
1   D  0.242591  0.553885
2   D  0.242591 -1.179391
3   E      NaN  0.199211
```

FULL JOIN

pandas also allows for FULL JOINS, which display both sides of the dataset, whether or not the joined columns find a match. As of writing, FULL JOINS are not supported in all RDBMS (MySQL).

```
-- show all records from both tables
SELECT *
FROM df1
FULL OUTER JOIN df2
ON df1.key = df2.key;
```

```
# show all records from both frames
In [30]: pd.merge(df1, df2, on='key', how='outer')
Out[30]:
  key    value_x    value_y
0   A -0.061166      NaN
1   B -1.491089  0.499188
2   C  0.612852      NaN
3   D  0.242591  0.553885
4   D  0.242591 -1.179391
5   E      NaN  0.199211
```

UNION

UNION ALL can be performed using `concat()`.

```
In [31]: df1 = pd.DataFrame({'city': ['Chicago', 'San Francisco', 'New York City'],
.....:                      'rank': range(1, 4)})
.....:

In [32]: df2 = pd.DataFrame({'city': ['Chicago', 'Boston', 'Los Angeles'],
.....:                      'rank': [1, 4, 5]})
.....:
```

```
SELECT city, rank
FROM df1
UNION ALL
SELECT city, rank
FROM df2;
/*
      city  rank
Chicago      1
San Francisco 2
New York City 3
      Chicago      1
      Boston        4
    Los Angeles      5
*/
```

In [33]: pd.concat([df1, df2])

Out[33]:

```
      city  rank
0    Chicago      1
1  San Francisco  2
2  New York City  3
0    Chicago      1
1    Boston        4
2  Los Angeles      5
```

SQL's UNION is similar to UNION ALL, however UNION will remove duplicate rows.

```
SELECT city, rank
FROM df1
UNION
SELECT city, rank
FROM df2;
-- notice that there is only one Chicago record this time
/*
      city  rank
Chicago      1
San Francisco 2
New York City 3
      Boston        4
    Los Angeles      5
*/
```

In pandas, you can use `concat()` in conjunction with `drop_duplicates()`.

In [34]: pd.concat([df1, df2]).drop_duplicates()

Out[34]:

```
      city  rank
0    Chicago      1
1  San Francisco  2
2  New York City  3
1    Boston        4
2  Los Angeles      5
```

Pandas equivalents for some SQL analytic and aggregate functions

Top N rows with offset

```
-- MySQL
SELECT * FROM tips
ORDER BY tip DESC
LIMIT 10 OFFSET 5;
```

In [35]: `tips.nlargest(10 + 5, columns='tip').tail(10)`

Out[35]:

	total_bill	tip	sex	smoker	day	time	size
183	23.17	6.50	Male	Yes	Sun	Dinner	4
214	28.17	6.50	Female	Yes	Sat	Dinner	3
47	32.40	6.00	Male	No	Sun	Dinner	4
239	29.03	5.92	Male	No	Sat	Dinner	3
88	24.71	5.85	Male	No	Thur	Lunch	2
181	23.33	5.65	Male	Yes	Sun	Dinner	2
44	30.40	5.60	Male	No	Sun	Dinner	4
52	34.81	5.20	Female	No	Sun	Dinner	4
85	34.83	5.17	Female	No	Thur	Lunch	4
211	25.89	5.16	Male	Yes	Sat	Dinner	4

Top N rows per group

```
-- Oracle's ROW_NUMBER() analytic function
SELECT * FROM (
    SELECT
        t.*,
        ROW_NUMBER() OVER(PARTITION BY day ORDER BY total_bill DESC) AS rn
    FROM tips t
)
WHERE rn < 3
ORDER BY day, rn;
```

In [36]: `(tips.assign(rn=tips.sort_values(['total_bill']), ascending=False)
.....: .groupby(['day'])
.....: .cumcount() + 1)
.....: .query('rn < 3')
.....: .sort_values(['day', 'rn']))`

Out[36]:

	total_bill	tip	sex	smoker	day	time	size	rn
95	40.17	4.73	Male	Yes	Fri	Dinner	4	1
90	28.97	3.00	Male	Yes	Fri	Dinner	2	2
170	50.81	10.00	Male	Yes	Sat	Dinner	3	1
212	48.33	9.00	Male	No	Sat	Dinner	4	2
156	48.17	5.00	Male	No	Sun	Dinner	6	1
182	45.35	3.50	Male	Yes	Sun	Dinner	3	2
197	43.11	5.00	Female	Yes	Thur	Lunch	4	1
142	41.19	5.00	Male	No	Thur	Lunch	5	2

the same using `rank(method='first')` function

```
In [37]: (tips.assign(rnk=tips.groupby(['day'])['total_bill']
.....           .rank(method='first', ascending=False))
.....           .query('rnk < 3')
.....           .sort_values(['day', 'rnk']))
.....
```

Out[37]:

	total_bill	tip	sex	smoker	day	time	size	rnk
95	40.17	4.73	Male	Yes	Fri	Dinner	4	1.0
90	28.97	3.00	Male	Yes	Fri	Dinner	2	2.0
170	50.81	10.00	Male	Yes	Sat	Dinner	3	1.0
212	48.33	9.00	Male	No	Sat	Dinner	4	2.0
156	48.17	5.00	Male	No	Sun	Dinner	6	1.0
182	45.35	3.50	Male	Yes	Sun	Dinner	3	2.0
197	43.11	5.00	Female	Yes	Thur	Lunch	4	1.0
142	41.19	5.00	Male	No	Thur	Lunch	5	2.0

```
-- Oracle's RANK() analytic function
SELECT * FROM (
    SELECT
        t.*,
        RANK() OVER(PARTITION BY sex ORDER BY tip) AS rnk
    FROM tips t
    WHERE tip < 2
)
WHERE rnk < 3
ORDER BY sex, rnk;
```

Let's find tips with (rank < 3) per gender group for (tips < 2). Notice that when using `rank(method='min')` function `rnk_min` remains the same for the same `tip` (as Oracle's RANK() function)

```
In [38]: (tips[tips['tip'] < 2]
.....       .assign(rnk_min=tips.groupby(['sex'])['tip']
.....                   .rank(method='min'))
.....       .query('rnk_min < 3')
.....       .sort_values(['sex', 'rnk_min']))
.....
```

Out[38]:

	total_bill	tip	sex	smoker	day	time	size	rnk_min
67	3.07	1.00	Female	Yes	Sat	Dinner	1	1.0
92	5.75	1.00	Female	Yes	Fri	Dinner	2	1.0
111	7.25	1.00	Female	No	Sat	Dinner	1	1.0
236	12.60	1.00	Male	Yes	Sat	Dinner	2	1.0
237	32.83	1.17	Male	Yes	Sat	Dinner	2	2.0

UPDATE

```
UPDATE tips
SET tip = tip*2
WHERE tip < 2;
```

```
In [39]: tips.loc[tips['tip'] < 2, 'tip'] *= 2
```

DELETE

```
DELETE FROM tips
WHERE tip > 9;
```

In pandas we select the rows that should remain, instead of deleting them

```
In [40]: tips = tips.loc[tips['tip'] <= 9]
```

```
{{ header }}
```

2.6.3 Comparison with SAS

For potential users coming from [SAS](#) this page is meant to demonstrate how different SAS operations would be performed in pandas.

If you're new to pandas, you might want to first read through [10 Minutes to pandas](#) to familiarize yourself with the library.

As is customary, we import pandas and NumPy as follows:

```
In [1]: import pandas as pd
In [2]: import numpy as np
```

Note: Throughout this tutorial, the pandas DataFrame will be displayed by calling `df.head()`, which displays the first N (default 5) rows of the DataFrame. This is often used in interactive work (e.g. [Jupyter notebook](#) or terminal) - the equivalent in SAS would be:

```
proc print data=df(obs=5);
run;
```

Data structures

General terminology translation

pandas	SAS
DataFrame	data set
column	variable
row	observation
groupby	BY-group
NaN	.

DataFrame / Series

A DataFrame in pandas is analogous to a SAS data set - a two-dimensional data source with labeled columns that can be of different types. As will be shown in this document, almost any operation that can be applied to a data set using SAS's DATA step, can also be accomplished in pandas.

A Series is the data structure that represents one column of a DataFrame. SAS doesn't have a separate data structure for a single column, but in general, working with a Series is analogous to referencing a column in the DATA step.

Index

Every DataFrame and Series has an Index - which are labels on the *rows* of the data. SAS does not have an exactly analogous concept. A data set's rows are essentially unlabeled, other than an implicit integer index that can be accessed during the DATA step (_N_).

In pandas, if no index is specified, an integer index is also used by default (first row = 0, second row = 1, and so on). While using a labeled Index or MultiIndex can enable sophisticated analyses and is ultimately an important part of pandas to understand, for this comparison we will essentially ignore the Index and just treat the DataFrame as a collection of columns. Please see the [indexing documentation](#) for much more on how to use an Index effectively.

Data input / output

Constructing a DataFrame from values

A SAS data set can be built from specified values by placing the data after a datalines statement and specifying the column names.

```
data df;
  input x y;
  datalines;
  1 2
  3 4
  5 6
;
run;
```

A pandas DataFrame can be constructed in many different ways, but for a small number of values, it is often convenient to specify it as a Python dictionary, where the keys are the column names and the values are the data.

```
In [3]: df = pd.DataFrame({'x': [1, 3, 5], 'y': [2, 4, 6]})

In [4]: df
Out[4]:
   x   y
0  1  2
1  3  4
2  5  6
```

Reading external data

Like SAS, pandas provides utilities for reading in data from many formats. The `tips` dataset, found within the pandas tests (`csv`) will be used in many of the following examples.

SAS provides PROC IMPORT to read csv data into a data set.

```
proc import datafile='tips.csv' dbms=csv out=tips replace;
  getnames=yes;
run;
```

The pandas method is `read_csv()`, which works similarly.

```
In [5]: url = ('https://raw.github.com/pandas-dev/'
...:           'pandas/master/pandas/tests/data/tips.csv')
...:

In [6]: tips = pd.read_csv(url)

In [7]: tips.head()
Out[7]:
   total_bill    tip      sex smoker  day    time    size
0       16.99  1.01  Female     No  Sun  Dinner      2
1       10.34  1.66    Male     No  Sun  Dinner      3
2       21.01  3.50    Male     No  Sun  Dinner      3
3       23.68  3.31    Male     No  Sun  Dinner      2
4       24.59  3.61  Female     No  Sun  Dinner      4
```

Like PROC IMPORT, `read_csv` can take a number of parameters to specify how the data should be parsed. For example, if the data was instead tab delimited, and did not have column names, the pandas command would be:

```
tips = pd.read_csv('tips.csv', sep='\t', header=None)

# alternatively, read_table is an alias to read_csv with tab delimiter
tips = pd.read_table('tips.csv', header=None)
```

In addition to text/csv, pandas supports a variety of other data formats such as Excel, HDF5, and SQL databases. These are all read via a `pd.read_*` function. See the [IO documentation](#) for more details.

Exporting data

The inverse of PROC IMPORT in SAS is PROC EXPORT

```
proc export data=tips outfile='tips2.csv' dbms=csv;
run;
```

Similarly in pandas, the opposite of `read_csv` is `to_csv()`, and other data formats follow a similar api.

```
tips.to_csv('tips2.csv')
```

Data operations

Operations on columns

In the DATA step, arbitrary math expressions can be used on new or existing columns.

```
data tips;
  set tips;
  total_bill = total_bill - 2;
  new_bill = total_bill / 2;
run;
```

pandas provides similar vectorized operations by specifying the individual Series in the DataFrame. New columns can be assigned in the same way.

```
In [8]: tips['total_bill'] = tips['total_bill'] - 2

In [9]: tips['new_bill'] = tips['total_bill'] / 2.0

In [10]: tips.head()
Out[10]:
   total_bill    tip      sex smoker  day    time  size  new_bill
0      14.99  1.01  Female     No  Sun  Dinner    2    7.495
1       8.34  1.66    Male     No  Sun  Dinner    3    4.170
2      19.01  3.50    Male     No  Sun  Dinner    3    9.505
3      21.68  3.31    Male     No  Sun  Dinner    2   10.840
4      22.59  3.61  Female     No  Sun  Dinner    4   11.295
```

Filtering

Filtering in SAS is done with an `if` or `where` statement, on one or more columns.

```
data tips;
  set tips;
  if total_bill > 10;
run;

data tips;
  set tips;
  where total_bill > 10;
  /* equivalent in this case - where happens before the
     DATA step begins and can also be used in PROC statements */
run;
```

DataFrames can be filtered in multiple ways; the most intuitive of which is using *boolean indexing*

```
In [11]: tips[tips['total_bill'] > 10].head()
Out[11]:
   total_bill    tip      sex smoker  day    time  size
0      14.99  1.01  Female     No  Sun  Dinner    2
2      19.01  3.50    Male     No  Sun  Dinner    3
3      21.68  3.31    Male     No  Sun  Dinner    2
4      22.59  3.61  Female     No  Sun  Dinner    4
5      23.29  4.71    Male     No  Sun  Dinner    4
```

If/then logic

In SAS, if/then logic can be used to create new columns.

```
data tips;
  set tips;
  format bucket $4.;

  if total_bill < 10 then bucket = 'low';
  else bucket = 'high';
run;
```

The same operation in pandas can be accomplished using the `where` method from numpy.

```
In [12]: tips['bucket'] = np.where(tips['total_bill'] < 10, 'low', 'high')

In [13]: tips.head()
Out[13]:
   total_bill    tip      sex smoker  day     time    size  bucket
0        14.99  1.01  Female     No  Sun Dinner      2    high
1         8.34  1.66    Male     No  Sun Dinner      3    low
2        19.01  3.50    Male     No  Sun Dinner      3    high
3        21.68  3.31    Male     No  Sun Dinner      2    high
4        22.59  3.61  Female     No  Sun Dinner      4    high
```

Date functionality

SAS provides a variety of functions to do operations on date/datetime columns.

```
data tips;
  set tips;
  format date1 date2 date1_plusmonth mmddyy10.;
  date1 = mdy(1, 15, 2013);
  date2 = mdy(2, 15, 2015);
  date1_year = year(date1);
  date2_month = month(date2);
  * shift date to beginning of next interval;
  date1_next = intnx('MONTH', date1, 1);
  * count intervals between dates;
  months_between = intck('MONTH', date1, date2);
run;
```

The equivalent pandas operations are shown below. In addition to these functions pandas supports other Time Series features not available in Base SAS (such as resampling and custom offsets) - see the [timeseries documentation](#) for more details.

```
In [14]: tips['date1'] = pd.Timestamp('2013-01-15')

In [15]: tips['date2'] = pd.Timestamp('2015-02-15')

In [16]: tips['date1_year'] = tips['date1'].dt.year

In [17]: tips['date2_month'] = tips['date2'].dt.month

In [18]: tips['date1_next'] = tips['date1'] + pd.offsets.MonthBegin()
```

(continues on next page)

(continued from previous page)

```
In [19]: tips['months_between'] = (
....:     tips['date2'].dt.to_period('M') - tips['date1'].dt.to_period('M'))
....:

In [20]: tips[['date1', 'date2', 'date1_year', 'date2_month',
....:             'date1_next', 'months_between']].head()
....:

Out[20]:
      date1      date2  date1_year  date2_month date1_next    months_between
0 2013-01-15 2015-02-15        2013            2 2013-02-01 <25 * MonthEnds>
1 2013-01-15 2015-02-15        2013            2 2013-02-01 <25 * MonthEnds>
2 2013-01-15 2015-02-15        2013            2 2013-02-01 <25 * MonthEnds>
3 2013-01-15 2015-02-15        2013            2 2013-02-01 <25 * MonthEnds>
4 2013-01-15 2015-02-15        2013            2 2013-02-01 <25 * MonthEnds>
```

Selection of columns

SAS provides keywords in the DATA step to select, drop, and rename columns.

```
data tips;
  set tips;
  keep sex total_bill tip;
run;

data tips;
  set tips;
  drop sex;
run;

data tips;
  set tips;
  rename total_bill=total_bill_2;
run;
```

The same operations are expressed in pandas below.

```
# keep
In [21]: tips[['sex', 'total_bill', 'tip']].head()
Out[21]:
      sex  total_bill  tip
0  Female       14.99  1.01
1    Male        8.34  1.66
2    Male       19.01  3.50
3    Male       21.68  3.31
4  Female       22.59  3.61

# drop
In [22]: tips.drop('sex', axis=1).head()
Out[22]:
      total_bill  tip  smoker  day   time  size
0         14.99  1.01     No  Sun Dinner     2
1          8.34  1.66     No  Sun Dinner     3
2         19.01  3.50     No  Sun Dinner     3
3         21.68  3.31     No  Sun Dinner     2
```

(continues on next page)

(continued from previous page)

```
4      22.59  3.61     No   Sun   Dinner      4

# rename
In [23]: tips.rename(columns={'total_bill': 'total_bill_2'}).head()
Out[23]:
   total_bill_2  tip    sex smoker  day    time  size
0        14.99  1.01  Female    No  Sun  Dinner     2
1         8.34  1.66   Male    No  Sun  Dinner     3
2        19.01  3.50   Male    No  Sun  Dinner     3
3        21.68  3.31   Male    No  Sun  Dinner     2
4        22.59  3.61  Female    No  Sun  Dinner     4
```

Sorting by values

Sorting in SAS is accomplished via PROC SORT

```
proc sort data=tips;
  by sex total_bill;
run;
```

pandas objects have a `sort_values()` method, which takes a list of columns to sort by.

```
In [24]: tips = tips.sort_values(['sex', 'total_bill'])
```

```
In [25]: tips.head()
```

```
Out[25]:
   total_bill  tip    sex smoker  day    time  size
67        1.07  1.00  Female    Yes  Sat  Dinner     1
92        3.75  1.00  Female    Yes  Fri  Dinner     2
111       5.25  1.00  Female    No   Sat  Dinner     1
145       6.35  1.50  Female    No  Thur  Lunch     2
135       6.51  1.25  Female    No  Thur  Lunch     2
```

String processing

Length

SAS determines the length of a character string with the LENGTHN and LENGTHC functions. LENGTHN excludes trailing blanks and LENGTHC includes trailing blanks.

```
data _null_;
set tips;
put (LENGTHN(time));
put (LENGTHC(time));
run;
```

Python determines the length of a character string with the `len` function. `len` includes trailing blanks. Use `len` and `rstrip` to exclude trailing blanks.

```
In [26]: tips['time'].str.len().head()
```

```
Out[26]:
```

```
67      6
```

(continues on next page)

(continued from previous page)

```
92      6
111     6
145     5
135     5
Name: time, dtype: int64

In [27]: tips['time'].str.rstrip().str.len().head()
Out[27]:
67      6
92      6
111     6
145     5
135     5
Name: time, dtype: int64
```

Find

SAS determines the position of a character in a string with the `FINDW` function. `FINDW` takes the string defined by the first argument and searches for the first position of the substring you supply as the second argument.

```
data _null_;
set tips;
put (FINDW(sex,'ale')) ;
run;
```

Python determines the position of a character in a string with the `find` function. `find` searches for the first position of the substring. If the substring is found, the function returns its position. Keep in mind that Python indexes are zero-based and the function will return -1 if it fails to find the substring.

```
In [28]: tips['sex'].str.find("ale").head()
Out[28]:
67      3
92      3
111     3
145     3
135     3
Name: sex, dtype: int64
```

Substring

SAS extracts a substring from a string based on its position with the `SUBSTR` function.

```
data _null_;
set tips;
put (substr(sex,1,1)) ;
run;
```

With pandas you can use `[]` notation to extract a substring from a string by position locations. Keep in mind that Python indexes are zero-based.

```
In [29]: tips['sex'].str[0:1].head()
Out[29]:
```

(continues on next page)

(continued from previous page)

```
67      F
92      F
111     F
145     F
135     F
Name: sex, dtype: object
```

Scan

The SAS `SCAN` function returns the nth word from a string. The first argument is the string you want to parse and the second argument specifies which word you want to extract.

```
data firstlast;
input String $60.;
First_Name = scan(string, 1);
Last_Name = scan(string, -1);
datalines2;
John Smith;
Jane Cook;
;;
run;
```

Python extracts a substring from a string based on its text by using regular expressions. There are much more powerful approaches, but this just shows a simple approach.

```
In [30]: firstlast = pd.DataFrame({'String': ['John Smith', 'Jane Cook']})

In [31]: firstlast['First_Name'] = firstlast['String'].str.split(" ", expand=True)[0]

In [32]: firstlast['Last_Name'] = firstlast['String'].str.rsplit(" ", expand=True)[0]

In [33]: firstlast
Out[33]:
   String First_Name Last_Name
0  John Smith       John       John
1  Jane Cook        Jane       Jane
```

Uppercase, lowercase, and propcase

The SAS `UPCASE LOWCASE` and `PROPCASE` functions change the case of the argument.

```
data firstlast;
input String $60.;
string_up = UPCASE(string);
string_low = LOWCASE(string);
string_prop = PROPCASE(string);
datalines2;
John Smith;
Jane Cook;
;;
run;
```

The equivalent Python functions are `upper`, `lower`, and `title`.

```
In [34]: firstlast = pd.DataFrame({'String': ['John Smith', 'Jane Cook']})

In [35]: firstlast['string_up'] = firstlast['String'].str.upper()

In [36]: firstlast['string_low'] = firstlast['String'].str.lower()

In [37]: firstlast['string_prop'] = firstlast['String'].str.title()

In [38]: firstlast
Out[38]:
      String    string_up   string_low  string_prop
0  John Smith     JOHN SMITH  john smith  John Smith
1  Jane Cook      JANE COOK   jane cook   Jane Cook
```

Merging

The following tables will be used in the merge examples

```
In [39]: df1 = pd.DataFrame({'key': ['A', 'B', 'C', 'D'],
....:                      'value': np.random.randn(4)})

In [40]: df1
Out[40]:
   key      value
0   A -0.360144
1   B -0.875363
2   C -0.102693
3   D -0.760507

In [41]: df2 = pd.DataFrame({'key': ['B', 'D', 'D', 'E'],
....:                      'value': np.random.randn(4)})

In [42]: df2
Out[42]:
   key      value
0   B -0.170410
1   D  0.578042
2   D  0.711777
3   E -0.179894
```

In SAS, data must be explicitly sorted before merging. Different types of joins are accomplished using the `in=` dummy variables to track whether a match was found in one or both input frames.

```
proc sort data=df1;
  by key;
run;

proc sort data=df2;
  by key;
run;

data left_join inner_join right_join outer_join;
  merge df1(in=a) df2(in=b);
```

(continues on next page)

(continued from previous page)

```

if a and b then output inner_join;
if a then output left_join;
if b then output right_join;
if a or b then output outer_join;
run;

```

pandas DataFrames have a `merge()` method, which provides similar functionality. Note that the data does not have to be sorted ahead of time, and different join types are accomplished via the `how` keyword.

```
In [43]: inner_join = df1.merge(df2, on=['key'], how='inner')
```

```
In [44]: inner_join
```

```
Out[44]:
```

	key	value_x	value_y
0	B	-0.875363	-0.170410
1	D	-0.760507	0.578042
2	D	-0.760507	0.711777

```
In [45]: left_join = df1.merge(df2, on=['key'], how='left')
```

```
In [46]: left_join
```

```
Out[46]:
```

	key	value_x	value_y
0	A	-0.360144	NaN
1	B	-0.875363	-0.170410
2	C	-0.102693	NaN
3	D	-0.760507	0.578042
4	D	-0.760507	0.711777

```
In [47]: right_join = df1.merge(df2, on=['key'], how='right')
```

```
In [48]: right_join
```

```
Out[48]:
```

	key	value_x	value_y
0	B	-0.875363	-0.170410
1	D	-0.760507	0.578042
2	D	-0.760507	0.711777
3	E	NaN	-0.179894

```
In [49]: outer_join = df1.merge(df2, on=['key'], how='outer')
```

```
In [50]: outer_join
```

```
Out[50]:
```

	key	value_x	value_y
0	A	-0.360144	NaN
1	B	-0.875363	-0.170410
2	C	-0.102693	NaN
3	D	-0.760507	0.578042
4	D	-0.760507	0.711777
5	E	NaN	-0.179894

Missing data

Like SAS, pandas has a representation for missing data - which is the special float value NaN (not a number). Many of the semantics are the same, for example missing data propagates through numeric operations, and is ignored by default for aggregations.

```
In [51]: outer_join
Out[51]:
   key    value_x    value_y
0     A -0.360144      NaN
1     B -0.875363 -0.170410
2     C -0.102693      NaN
3     D -0.760507  0.578042
4     D -0.760507  0.711777
5     E      NaN -0.179894

In [52]: outer_join['value_x'] + outer_join['value_y']
Out[52]:
0        NaN
1   -1.045773
2        NaN
3   -0.182465
4   -0.048730
5        NaN
dtype: float64

In [53]: outer_join['value_x'].sum()
Out[53]: -2.859214759745549
```

One difference is that missing data cannot be compared to its sentinel value. For example, in SAS you could do this to filter missing values.

```
data outer_join_nulls;
  set outer_join;
  if value_x = .;
run;

data outer_join_no_nulls;
  set outer_join;
  if value_x ^= .;
run;
```

Which doesn't work in pandas. Instead, the pd.isna or pd.notna functions should be used for comparisons.

```
In [54]: outer_join[pd.isna(outer_join['value_x'])]
Out[54]:
   key    value_x    value_y
5     E      NaN -0.179894

In [55]: outer_join[pd.notna(outer_join['value_x'])]
Out[55]:
   key    value_x    value_y
0     A -0.360144      NaN
1     B -0.875363 -0.170410
2     C -0.102693      NaN
3     D -0.760507  0.578042
4     D -0.760507  0.711777
```

pandas also provides a variety of methods to work with missing data - some of which would be challenging to express in SAS. For example, there are methods to drop all rows with any missing values, replacing missing values with a specified value, like the mean, or forward filling from previous rows. See the [missing data documentation](#) for more.

```
In [56]: outer_join.dropna()
Out[56]:
   key    value_x    value_y
1    B -0.875363 -0.170410
3    D -0.760507  0.578042
4    D -0.760507  0.711777

In [57]: outer_join.fillna(method='ffill')
Out[57]:
   key    value_x    value_y
0    A -0.360144      NaN
1    B -0.875363 -0.170410
2    C -0.102693 -0.170410
3    D -0.760507  0.578042
4    D -0.760507  0.711777
5    E -0.760507 -0.179894

In [58]: outer_join['value_x'].fillna(outer_join['value_x'].mean())
Out[58]:
0    -0.360144
1    -0.875363
2    -0.102693
3    -0.760507
4    -0.760507
5    -0.571843
Name: value_x, dtype: float64
```

GroupBy

Aggregation

SAS's PROC SUMMARY can be used to group by one or more key variables and compute aggregations on numeric columns.

```
proc summary data=tips nway;
  class sex smoker;
  var total_bill tip;
  output out=tips_summed sum=;
run;
```

pandas provides a flexible groupby mechanism that allows similar aggregations. See the [groupby documentation](#) for more details and examples.

```
In [59]: tips_summed = tips.groupby(['sex', 'smoker'])[['total_bill', 'tip']].sum()

In [60]: tips_summed.head()
Out[60]:
          total_bill      tip
sex   smoker
Female No        869.68  149.77
      Yes       527.27   96.74
```

(continues on next page)

(continued from previous page)

Male	No	1725.75	302.00
	Yes	1217.07	183.07

Transformation

In SAS, if the group aggregations need to be used with the original frame, it must be merged back together. For example, to subtract the mean for each observation by smoker group.

```
proc summary data=tips missing nway;
  class smoker;
  var total_bill;
  output out=smoker_means mean(total_bill)=group_bill;
run;

proc sort data=tips;
  by smoker;
run;

data tips;
  merge tips(in=a) smoker_means (in=b);
  by smoker;
  adj_total_bill = total_bill - group_bill;
  if a and b;
run;
```

pandas groupby provides a `transform` mechanism that allows these type of operations to be succinctly expressed in one operation.

```
In [61]: gb = tips.groupby('smoker')['total_bill']

In [62]: tips['adj_total_bill'] = tips['total_bill'] - gb.transform('mean')

In [63]: tips.head()
Out[63]:
   total_bill  tip    sex smoker  day   time  size  adj_total_bill
67      1.07  1.00  Female    Yes  Sat Dinner     1   -17.686344
92      3.75  1.00  Female    Yes  Fri Dinner     2   -15.006344
111     5.25  1.00  Female    No   Sat Dinner     1   -11.938278
145     6.35  1.50  Female    No  Thur Lunch     2   -10.838278
135     6.51  1.25  Female    No  Thur Lunch     2   -10.678278
```

By group processing

In addition to aggregation, pandas groupby can be used to replicate most other by group processing from SAS. For example, this DATA step reads the data by sex/smoker group and filters to the first entry for each.

```
proc sort data=tips;
  by sex smoker;
run;

data tips_first;
  set tips;
  by sex smoker;
```

(continues on next page)

(continued from previous page)

```
if FIRST.sex or FIRST.smoker then output;
run;
```

In pandas this would be written as:

		total_bill	tip	day	time	size	adj_total_bill
sex	smoker						
Female	No	5.25	1.00	Sat	Dinner	1	-11.938278
	Yes	1.07	1.00	Sat	Dinner	1	-17.686344
Male	No	5.51	2.00	Thur	Lunch	2	-11.678278
	Yes	5.25	5.15	Sun	Dinner	2	-13.506344

Other Considerations

Disk vs memory

pandas operates exclusively in memory, where a SAS data set exists on disk. This means that the size of data able to be loaded in pandas is limited by your machine's memory, but also that the operations on that data may be faster.

If out of core processing is needed, one possibility is the `dask.dataframe` library (currently in development) which provides a subset of pandas functionality for an on-disk DataFrame

Data interop

pandas provides a `read_sas()` method that can read SAS data saved in the XPORT or SAS7BDAT binary format.

```
libname xportout xport 'transport-file.xpt';
data xportout.tips;
  set tips(rename=(total_bill=tbill));
  /* xport variable names limited to 6 characters;
run;
```

```
df = pd.read_sas('transport-file.xpt')
df = pd.read_sas('binary-file.sas7bdat')
```

You can also specify the file format directly. By default, pandas will try to infer the file format based on its extension.

```
df = pd.read_sas('transport-file.xpt', format='xport')
df = pd.read_sas('binary-file.sas7bdat', format='sas7bdat')
```

XPORT is a relatively limited format and the parsing of it is not as optimized as some of the other pandas readers. An alternative way to interop data between SAS and pandas is to serialize to csv.

```
# version 0.17, 10M rows

In [8]: %time df = pd.read_sas('big.xpt')
Wall time: 14.6 s

In [9]: %time df = pd.read_csv('big.csv')
Wall time: 4.86 s
```

{{ header }}

2.6.4 Comparison with Stata

For potential users coming from [Stata](#) this page is meant to demonstrate how different Stata operations would be performed in pandas.

If you're new to pandas, you might want to first read through [10 Minutes to pandas](#) to familiarize yourself with the library.

As is customary, we import pandas and NumPy as follows. This means that we can refer to the libraries as `pd` and `np`, respectively, for the rest of the document.

```
In [1]: import pandas as pd
```

```
In [2]: import numpy as np
```

Note: Throughout this tutorial, the pandas `DataFrame` will be displayed by calling `df.head()`, which displays the first N (default 5) rows of the `DataFrame`. This is often used in interactive work (e.g. [Jupyter notebook](#) or terminal) – the equivalent in Stata would be:

```
list in 1/5
```

Data structures

General terminology translation

pandas	Stata
<code>DataFrame</code>	data set
<code>column</code>	variable
<code>row</code>	observation
<code>groupby</code>	bysort
<code>NaN</code>	.

DataFrame / Series

A `DataFrame` in pandas is analogous to a Stata data set – a two-dimensional data source with labeled columns that can be of different types. As will be shown in this document, almost any operation that can be applied to a data set in Stata can also be accomplished in pandas.

A `Series` is the data structure that represents one column of a `DataFrame`. Stata doesn't have a separate data structure for a single column, but in general, working with a `Series` is analogous to referencing a column of a data set in Stata.

Index

Every DataFrame and Series has an Index – labels on the *rows* of the data. Stata does not have an exactly analogous concept. In Stata, a data set's rows are essentially unlabeled, other than an implicit integer index that can be accessed with `_n`.

In pandas, if no index is specified, an integer index is also used by default (first row = 0, second row = 1, and so on). While using a labeled Index or MultiIndex can enable sophisticated analyses and is ultimately an important part of pandas to understand, for this comparison we will essentially ignore the Index and just treat the DataFrame as a collection of columns. Please see the [indexing documentation](#) for much more on how to use an Index effectively.

Data input / output

Constructing a DataFrame from values

A Stata data set can be built from specified values by placing the data after an `input` statement and specifying the column names.

```
input x y
1 2
3 4
5 6
end
```

A pandas DataFrame can be constructed in many different ways, but for a small number of values, it is often convenient to specify it as a Python dictionary, where the keys are the column names and the values are the data.

```
In [3]: df = pd.DataFrame({'x': [1, 3, 5], 'y': [2, 4, 6]})

In [4]: df
Out[4]:
   x  y
0  1  2
1  3  4
2  5  6
```

Reading external data

Like Stata, pandas provides utilities for reading in data from many formats. The `tips` data set, found within the pandas tests (`csv`) will be used in many of the following examples.

Stata provides `import delimited` to read csv data into a data set in memory. If the `tips.csv` file is in the current working directory, we can import it as follows.

```
import delimited tips.csv
```

The pandas method is `read_csv()`, which works similarly. Additionally, it will automatically download the data set if presented with a url.

```
In [5]: url = ('https://raw.github.com/pandas-dev'
...:      '/pandas/master/pandas/tests/data/tips.csv')
...
In [6]: tips = pd.read_csv(url)
```

(continues on next page)

(continued from previous page)

```
In [7]: tips.head()
Out[7]:
   total_bill  tip    sex smoker  day    time  size
0      16.99  1.01  Female     No  Sun  Dinner     2
1      10.34  1.66    Male     No  Sun  Dinner     3
2      21.01  3.50    Male     No  Sun  Dinner     3
3      23.68  3.31    Male     No  Sun  Dinner     2
4      24.59  3.61  Female     No  Sun  Dinner     4
```

Like `import delimited`, `read_csv()` can take a number of parameters to specify how the data should be parsed. For example, if the data were instead tab delimited, did not have column names, and existed in the current working directory, the pandas command would be:

```
tips = pd.read_csv('tips.csv', sep='\t', header=None)

# alternatively, read_table is an alias to read_csv with tab delimiter
tips = pd.read_table('tips.csv', header=None)
```

Pandas can also read Stata data sets in `.dta` format with the `read_stata()` function.

```
df = pd.read_stata('data.dta')
```

In addition to text/csv and Stata files, pandas supports a variety of other data formats such as Excel, SAS, HDF5, Parquet, and SQL databases. These are all read via a `pd.read_*` function. See the [IO documentation](#) for more details.

Exporting data

The inverse of `import delimited` in Stata is `export delimited`

```
export delimited tips2.csv
```

Similarly in pandas, the opposite of `read_csv` is `DataFrame.to_csv()`.

```
tips.to_csv('tips2.csv')
```

Pandas can also export to Stata file format with the `DataFrame.to_stata()` method.

```
tips.to_stata('tips2.dta')
```

Data operations

Operations on columns

In Stata, arbitrary math expressions can be used with the `generate` and `replace` commands on new or existing columns. The `drop` command drops the column from the data set.

```
replace total_bill = total_bill - 2
generate new_bill = total_bill / 2
drop new_bill
```

pandas provides similar vectorized operations by specifying the individual Series in the DataFrame. New columns can be assigned in the same way. The DataFrame.drop() method drops a column from the DataFrame.

```
In [8]: tips['total_bill'] = tips['total_bill'] - 2
In [9]: tips['new_bill'] = tips['total_bill'] / 2
In [10]: tips.head()
Out[10]:
   total_bill  tip    sex smoker  day    time  size  new_bill
0      14.99  1.01  Female     No  Sun  Dinner    2    7.495
1       8.34  1.66    Male     No  Sun  Dinner    3    4.170
2      19.01  3.50    Male     No  Sun  Dinner    3    9.505
3      21.68  3.31    Male     No  Sun  Dinner    2   10.840
4      22.59  3.61  Female     No  Sun  Dinner    4   11.295
In [11]: tips = tips.drop('new_bill', axis=1)
```

Filtering

Filtering in Stata is done with an `if` clause on one or more columns.

```
list if total_bill > 10
```

DataFrames can be filtered in multiple ways; the most intuitive of which is using *boolean indexing*.

```
In [12]: tips[tips['total_bill'] > 10].head()
Out[12]:
   total_bill  tip    sex smoker  day    time  size
0      14.99  1.01  Female     No  Sun  Dinner    2
2      19.01  3.50    Male     No  Sun  Dinner    3
3      21.68  3.31    Male     No  Sun  Dinner    2
4      22.59  3.61  Female     No  Sun  Dinner    4
5      23.29  4.71    Male     No  Sun  Dinner    4
```

If/then logic

In Stata, an `if` clause can also be used to create new columns.

```
generate bucket = "low" if total_bill < 10
replace bucket = "high" if total_bill >= 10
```

The same operation in pandas can be accomplished using the `where` method from numpy.

```
In [13]: tips['bucket'] = np.where(tips['total_bill'] < 10, 'low', 'high')
In [14]: tips.head()
Out[14]:
   total_bill  tip    sex smoker  day    time  size  bucket
0      14.99  1.01  Female     No  Sun  Dinner    2    high
1       8.34  1.66    Male     No  Sun  Dinner    3    low
2      19.01  3.50    Male     No  Sun  Dinner    3    high
3      21.68  3.31    Male     No  Sun  Dinner    2    high
4      22.59  3.61  Female     No  Sun  Dinner    4    high
```

Date functionality

Stata provides a variety of functions to do operations on date/datetime columns.

```
generate date1 = mdy(1, 15, 2013)
generate date2 = date("Feb152015", "MDY")

generate date1_year = year(date1)
generate date2_month = month(date2)

* shift date to beginning of next month
generate date1_next = mdy(month(date1) + 1, 1, year(date1)) if month(date1) != 12
replace date1_next = mdy(1, 1, year(date1) + 1) if month(date1) == 12
generate months_between = mofd(date2) - mofd(date1)

list date1 date2 date1_year date2_month date1_next months_between
```

The equivalent pandas operations are shown below. In addition to these functions, pandas supports other Time Series features not available in Stata (such as time zone handling and custom offsets) – see the [timeseries documentation](#) for more details.

```
In [15]: tips['date1'] = pd.Timestamp('2013-01-15')

In [16]: tips['date2'] = pd.Timestamp('2015-02-15')

In [17]: tips['date1_year'] = tips['date1'].dt.year

In [18]: tips['date2_month'] = tips['date2'].dt.month

In [19]: tips['date1_next'] = tips['date1'] + pd.offsets.MonthBegin()

In [20]: tips['months_between'] = (tips['date2'].dt.to_period('M')
....:                 - tips['date1'].dt.to_period('M'))
....:

In [21]: tips[['date1', 'date2', 'date1_year', 'date2_month', 'date1_next',
....:           'months_between']].head()
....:
Out[21]:
      date1      date2  date1_year  date2_month  date1_next  months_between
0 2013-01-15 2015-02-15      2013            2 2013-02-01 <25 * MonthEnds>
1 2013-01-15 2015-02-15      2013            2 2013-02-01 <25 * MonthEnds>
2 2013-01-15 2015-02-15      2013            2 2013-02-01 <25 * MonthEnds>
3 2013-01-15 2015-02-15      2013            2 2013-02-01 <25 * MonthEnds>
4 2013-01-15 2015-02-15      2013            2 2013-02-01 <25 * MonthEnds>
```

Selection of columns

Stata provides keywords to select, drop, and rename columns.

```
keep sex total_bill tip

drop sex

rename total_bill total_bill_2
```

The same operations are expressed in pandas below. Note that in contrast to Stata, these operations do not happen in place. To make these changes persist, assign the operation back to a variable.

```
# keep
In [22]: tips[['sex', 'total_bill', 'tip']].head()
Out[22]:
   sex  total_bill  tip
0  Female      14.99  1.01
1    Male       8.34  1.66
2    Male      19.01  3.50
3    Male      21.68  3.31
4  Female      22.59  3.61

# drop
In [23]: tips.drop('sex', axis=1).head()
Out[23]:
  total_bill  tip  smoker  day  time  size
0      14.99  1.01     No  Sun  Dinner    2
1       8.34  1.66     No  Sun  Dinner    3
2      19.01  3.50     No  Sun  Dinner    3
3      21.68  3.31     No  Sun  Dinner    2
4      22.59  3.61     No  Sun  Dinner    4

# rename
In [24]: tips.rename(columns={'total_bill': 'total_bill_2'}).head()
Out[24]:
  total_bill_2  tip  sex  smoker  day  time  size
0      14.99  1.01  Female     No  Sun  Dinner    2
1       8.34  1.66    Male     No  Sun  Dinner    3
2      19.01  3.50    Male     No  Sun  Dinner    3
3      21.68  3.31    Male     No  Sun  Dinner    2
4      22.59  3.61  Female     No  Sun  Dinner    4
```

Sorting by values

Sorting in Stata is accomplished via `sort`

```
sort sex total_bill
```

pandas objects have a `DataFrame.sort_values()` method, which takes a list of columns to sort by.

```
In [25]: tips = tips.sort_values(['sex', 'total_bill'])

In [26]: tips.head()
Out[26]:
  total_bill  tip  sex  smoker  day  time  size
67      1.07  1.00  Female    Yes  Sat  Dinner    1
92      3.75  1.00  Female    Yes  Fri  Dinner    2
111     5.25  1.00  Female     No  Sat  Dinner    1
145     6.35  1.50  Female     No  Thur  Lunch    2
135     6.51  1.25  Female     No  Thur  Lunch    2
```

String processing

Finding length of string

Stata determines the length of a character string with the `strlen()` and `ustrlen()` functions for ASCII and Unicode strings, respectively.

```
generate strlen_time = strlen(time)
generate ustrlen_time = ustrlen(time)
```

Python determines the length of a character string with the `len` function. In Python 3, all strings are Unicode strings. `len` includes trailing blanks. Use `len` and `rstrip` to exclude trailing blanks.

```
In [27]: tips['time'].str.len().head()
Out[27]:
67      6
92      6
111     6
145     5
135     5
Name: time, dtype: int64

In [28]: tips['time'].str.rstrip().str.len().head()
Out[28]:
67      6
92      6
111     6
145     5
135     5
Name: time, dtype: int64
```

Finding position of substring

Stata determines the position of a character in a string with the `strpos()` function. This takes the string defined by the first argument and searches for the first position of the substring you supply as the second argument.

```
generate str_position = strpos(sex, "ale")
```

Python determines the position of a character in a string with the `find()` function. `find` searches for the first position of the substring. If the substring is found, the function returns its position. Keep in mind that Python indexes are zero-based and the function will return -1 if it fails to find the substring.

```
In [29]: tips['sex'].str.find("ale").head()
Out[29]:
67      3
92      3
111     3
145     3
135     3
Name: sex, dtype: int64
```

Extracting substring by position

Stata extracts a substring from a string based on its position with the `substr()` function.

```
generate short_sex = substr(sex, 1, 1)
```

With pandas you can use `[]` notation to extract a substring from a string by position locations. Keep in mind that Python indexes are zero-based.

```
In [30]: tips['sex'].str[0:1].head()
Out[30]:
67      F
92      F
111     F
145     F
135     F
Name: sex, dtype: object
```

Extracting nth word

The Stata `word()` function returns the nth word from a string. The first argument is the string you want to parse and the second argument specifies which word you want to extract.

```
clear
input str20 string
"John Smith"
"Jane Cook"
end

generate first_name = word(name, 1)
generate last_name = word(name, -1)
```

Python extracts a substring from a string based on its text by using regular expressions. There are much more powerful approaches, but this just shows a simple approach.

```
In [31]: firstlast = pd.DataFrame({'string': ['John Smith', 'Jane Cook']})

In [32]: firstlast['First_Name'] = firstlast['string'].str.split(" ", expand=True)[0]

In [33]: firstlast['Last_Name'] = firstlast['string'].str.rsplit(" ", expand=True)[0]

In [34]: firstlast
Out[34]:
       string First_Name Last_Name
0   John Smith        John       John
1   Jane Cook         Jane       Jane
```

Changing case

The Stata `strupper()`, `strlower()`, `strproper()`, `ustrupper()`, `ustrlower()`, and `ustrtitle()` functions change the case of ASCII and Unicode strings, respectively.

```
clear
input str20 string
"John Smith"
"Jane Cook"
end

generate upper = strupper(string)
generate lower = strlower(string)
generate title = strproper(string)
list
```

The equivalent Python functions are `upper`, `lower`, and `title`.

```
In [35]: firstlast = pd.DataFrame({'string': ['John Smith', 'Jane Cook']})

In [36]: firstlast['upper'] = firstlast['string'].str.upper()

In [37]: firstlast['lower'] = firstlast['string'].str.lower()

In [38]: firstlast['title'] = firstlast['string'].str.title()

In [39]: firstlast
Out[39]:
      string      upper      lower      title
0  John Smith  JOHN SMITH  john smith  John Smith
1   Jane Cook   JANE COOK  jane cook   Jane Cook
```

Merging

The following tables will be used in the merge examples

```
In [40]: df1 = pd.DataFrame({'key': ['A', 'B', 'C', 'D'],
....:                         'value': np.random.randn(4)})

In [41]: df1
Out[41]:
    key      value
0    A -0.106122
1    B -0.208943
2    C  0.573582
3    D  0.517960

In [42]: df2 = pd.DataFrame({'key': ['B', 'D', 'D', 'E'],
....:                         'value': np.random.randn(4)})

In [43]: df2
Out[43]:
    key      value
0    B  0.433640
```

(continues on next page)

(continued from previous page)

```

1  D -0.649769
2  D -0.127587
3  E -0.192129

```

In Stata, to perform a merge, one data set must be in memory and the other must be referenced as a file name on disk. In contrast, Python must have both DataFrames already in memory.

By default, Stata performs an outer join, where all observations from both data sets are left in memory after the merge. One can keep only observations from the initial data set, the merged data set, or the intersection of the two by using the values created in the `_merge` variable.

```

* First create df2 and save to disk
clear
input str1 key
B
D
D
E
end
generate value = rnormal()
save df2.dta

* Now create df1 in memory
clear
input str1 key
A
B
C
D
end
generate value = rnormal()

preserve

* Left join
merge 1:n key using df2.dta
keep if _merge == 1

* Right join
restore, preserve
merge 1:n key using df2.dta
keep if _merge == 2

* Inner join
restore, preserve
merge 1:n key using df2.dta
keep if _merge == 3

* Outer join
restore
merge 1:n key using df2.dta

```

pandas DataFrames have a `DataFrame.merge()` method, which provides similar functionality. Note that different join types are accomplished via the `how` keyword.

```
In [44]: inner_join = df1.merge(df2, on=['key'], how='inner')
```

(continues on next page)

(continued from previous page)

```
In [45]: inner_join
Out[45]:
   key    value_x    value_y
0    B -0.208943  0.433640
1    D  0.517960 -0.649769
2    D  0.517960 -0.127587

In [46]: left_join = df1.merge(df2, on=['key'], how='left')

In [47]: left_join
Out[47]:
   key    value_x    value_y
0    A -0.106122      NaN
1    B -0.208943  0.433640
2    C  0.573582      NaN
3    D  0.517960 -0.649769
4    D  0.517960 -0.127587

In [48]: right_join = df1.merge(df2, on=['key'], how='right')

In [49]: right_join
Out[49]:
   key    value_x    value_y
0    B -0.208943  0.433640
1    D  0.517960 -0.649769
2    D  0.517960 -0.127587
3    E      NaN -0.192129

In [50]: outer_join = df1.merge(df2, on=['key'], how='outer')

In [51]: outer_join
Out[51]:
   key    value_x    value_y
0    A -0.106122      NaN
1    B -0.208943  0.433640
2    C  0.573582      NaN
3    D  0.517960 -0.649769
4    D  0.517960 -0.127587
5    E      NaN -0.192129
```

Missing data

Like Stata, pandas has a representation for missing data – the special float value `NaN` (not a number). Many of the semantics are the same; for example missing data propagates through numeric operations, and is ignored by default for aggregations.

```
In [52]: outer_join
Out[52]:
   key    value_x    value_y
0    A -0.106122      NaN
1    B -0.208943  0.433640
2    C  0.573582      NaN
3    D  0.517960 -0.649769
4    D  0.517960 -0.127587
5    E      NaN -0.192129
```

(continues on next page)

(continued from previous page)

```
In [53]: outer_join['value_x'] + outer_join['value_y']
Out[53]:
0      NaN
1    0.224697
2      NaN
3   -0.131809
4    0.390373
5      NaN
dtype: float64

In [54]: outer_join['value_x'].sum()
Out[54]: 1.294436475582241
```

One difference is that missing data cannot be compared to its sentinel value. For example, in Stata you could do this to filter missing values.

```
* Keep missing values
list if value_x == .
* Keep non-missing values
list if value_x != .
```

This doesn't work in pandas. Instead, the `pd.isna()` or `pd.notna()` functions should be used for comparisons.

```
In [55]: outer_join[pd.isna(outer_join['value_x'])]
Out[55]:
key  value_x  value_y
5     E      NaN -0.192129

In [56]: outer_join[pd.notna(outer_join['value_x'])]
Out[56]:
key  value_x  value_y
0     A -0.106122      NaN
1     B -0.208943  0.433640
2     C  0.573582      NaN
3     D  0.517960 -0.649769
4     D  0.517960 -0.127587
```

Pandas also provides a variety of methods to work with missing data – some of which would be challenging to express in Stata. For example, there are methods to drop all rows with any missing values, replacing missing values with a specified value, like the mean, or forward filling from previous rows. See the [missing data documentation](#) for more.

```
# Drop rows with any missing value
In [57]: outer_join.dropna()
Out[57]:
key  value_x  value_y
1     B -0.208943  0.433640
3     D  0.517960 -0.649769
4     D  0.517960 -0.127587

# Fill forwards
In [58]: outer_join.fillna(method='ffill')
Out[58]:
key  value_x  value_y
0     A -0.106122      NaN
1     B -0.208943  0.433640
```

(continues on next page)

(continued from previous page)

```
2   C  0.573582  0.433640
3   D  0.517960 -0.649769
4   D  0.517960 -0.127587
5   E  0.517960 -0.192129

# Impute missing values with the mean
In [59]: outer_join['value_x'].fillna(outer_join['value_x'].mean())
Out[59]:
0    -0.106122
1    -0.208943
2     0.573582
3     0.517960
4     0.517960
5     0.258887
Name: value_x, dtype: float64
```

GroupBy

Aggregation

Stata's `collapse` can be used to group by one or more key variables and compute aggregations on numeric columns.

```
collapse (sum) total_bill tip, by(sex smoker)
```

pandas provides a flexible `groupby` mechanism that allows similar aggregations. See the [groupby documentation](#) for more details and examples.

```
In [60]: tips_summed = tips.groupby(['sex', 'smoker'])[['total_bill', 'tip']].sum()

In [61]: tips_summed.head()
Out[61]:
          total_bill      tip
sex   smoker
Female  No        869.68  149.77
      Yes       527.27   96.74
Male   No       1725.75  302.00
      Yes      1217.07  183.07
```

Transformation

In Stata, if the group aggregations need to be used with the original data set, one would usually use `bysort` with `egen()`. For example, to subtract the mean for each observation by smoker group.

```
bysort sex smoker: egen group_bill = mean(total_bill)
generate adj_total_bill = total_bill - group_bill
```

pandas `groupby` provides a `transform` mechanism that allows these type of operations to be succinctly expressed in one operation.

```
In [62]: gb = tips.groupby('smoker')['total_bill']

In [63]: tips['adj_total_bill'] = tips['total_bill'] - gb.transform('mean')
```

(continues on next page)

(continued from previous page)

```
In [64]: tips.head()
Out[64]:
   total_bill  tip    sex smoker  day   time  size  adj_total_bill
67      1.07  1.00  Female    Yes  Sat  Dinner    1     -17.686344
92      3.75  1.00  Female    Yes  Fri  Dinner    2     -15.006344
111     5.25  1.00  Female    No   Sat  Dinner    1     -11.938278
145     6.35  1.50  Female    No  Thur  Lunch    2     -10.838278
135     6.51  1.25  Female    No  Thur  Lunch    2     -10.678278
```

By group processing

In addition to aggregation, pandas groupby can be used to replicate most other bysort processing from Stata. For example, the following example lists the first observation in the current sort order by sex/smoker group.

```
bysort sex smoker: list if _n == 1
```

In pandas this would be written as:

```
In [65]: tips.groupby(['sex', 'smoker']).first()
Out[65]:
   total_bill  tip    day   time  size  adj_total_bill
sex   smoker
Female  No      5.25  1.00  Sat  Dinner    1     -11.938278
        Yes     1.07  1.00  Sat  Dinner    1     -17.686344
Male   No      5.51  2.00  Thur  Lunch    2     -11.678278
        Yes     5.25  5.15  Sun  Dinner    2     -13.506344
```

Other considerations

Disk vs memory

Pandas and Stata both operate exclusively in memory. This means that the size of data able to be loaded in pandas is limited by your machine's memory. If out of core processing is needed, one possibility is the `dask.dataframe` library, which provides a subset of pandas functionality for an on-disk DataFrame. {{ header }}

2.7 Tutorials

This is a guide to many pandas tutorials, geared mainly for new users.

2.7.1 Internal guides

pandas' own *10 Minutes to pandas*.

More complex recipes are in the *Cookbook*.

A handy pandas [cheat sheet](#).

2.7.2 Community guides

pandas Cookbook by Julia Evans

The goal of this 2015 cookbook (by Julia Evans) is to give you some concrete examples for getting started with pandas. These are examples with real-world data, and all the bugs and weirdness that entails. For the table of contents, see the [pandas-cookbook GitHub repository](#).

Learn Pandas by Hernan Rojas

A set of lesson for new pandas users: <https://bitbucket.org/hrojas/learn-pandas>

Practical data analysis with Python

This [guide](#) is an introduction to the data analysis process using the Python data ecosystem and an interesting open dataset. There are four sections covering selected topics as [munging data](#), [aggregating data](#), [visualizing data](#) and [time series](#).

Exercises for new users

Practice your skills with real data sets and exercises. For more resources, please visit the main [repository](#).

USER GUIDE

The User Guide covers all of pandas by topic area. Each of the subsections introduces a topic (such as “working with missing data”), and discusses how pandas approaches the problem, with many examples throughout.

Users brand-new to pandas should start with 10min.

Further information on any specific method can be obtained in the *API reference*.

3.1 IO tools (text, CSV, HDF5, ...)

The pandas I/O API is a set of top level `reader` functions accessed like `pandas.read_csv()` that generally return a pandas object. The corresponding `writer` functions are object methods that are accessed like `DataFrame.to_csv()`. Below is a table containing available `readers` and `writers`.

Format Type	Data Description	Reader	Writer
text	CSV	<code>read_csv</code>	<code>to_csv</code>
text	Fixed-Width Text File	<code>read_fwf</code>	
text	JSON	<code>read_json</code>	<code>to_json</code>
text	HTML	<code>read_html</code>	<code>to_html</code>
text	Local clipboard	<code>read_clipboard</code>	<code>to_clipboard</code>
	MS Excel	<code>read_excel</code>	<code>to_excel</code>
binary	OpenDocument	<code>read_excel</code>	
binary	HDF5 Format	<code>read_hdf</code>	<code>to_hdf</code>
binary	Feather Format	<code>read_feather</code>	<code>to_feather</code>
binary	Parquet Format	<code>read_parquet</code>	<code>to_parquet</code>
binary	ORC Format	<code>read_orc</code>	
binary	Msgpack	<code>read_msgpack</code>	<code>to_msgpack</code>
binary	Stata	<code>read_stata</code>	<code>to_stata</code>
binary	SAS	<code>read_sas</code>	
binary	SPSS	<code>read_spss</code>	
binary	Python Pickle Format	<code>read_pickle</code>	<code>to_pickle</code>
SQL	SQL	<code>read_sql</code>	<code>to_sql</code>
SQL	Google BigQuery	<code>read_gbq</code>	<code>to_gbq</code>

Here is an informal performance comparison for some of these IO methods.

Note: For examples that use the `StringIO` class, make sure you import it according to your Python version, i.e. `from StringIO import StringIO` for Python 2 and `from io import StringIO` for Python 3.

3.1.1 CSV & text files

The workhorse function for reading text files (a.k.a. flat files) is `read_csv()`. See the *cookbook* for some advanced strategies.

Parsing options

`read_csv()` accepts the following common arguments:

Basic

filepath_or_buffer [various] Either a path to a file (a `str`, `pathlib.Path`, or `py._path.local.LocalPath`), URL (including http, ftp, and S3 locations), or any object with a `read()` method (such as an open file or `StringIO`).

sep [str, defaults to `,` ' ' for `read_csv()`, `\t` for `read_table()`] Delimiter to use. If `sep` is `None`, the C engine cannot automatically detect the separator, but the Python parsing engine can, meaning the latter will be used and automatically detect the separator by Python's builtin sniffer tool, `csv.Sniffer`. In addition, separators longer than 1 character and different from `'\s+'` will be interpreted as regular expressions and will also force the use of the Python parsing engine. Note that regex delimiters are prone to ignoring quoted data. Regex example: `'\\r\\t'`.

delimiter [str, default `None`] Alternative argument name for `sep`.

delim_whitespace [boolean, default `False`] Specifies whether or not whitespace (e.g. ' ' or '`\t`') will be used as the delimiter. Equivalent to setting `sep='\\s+'`. If this option is set to `True`, nothing should be passed in for the `delimiter` parameter.

Column and index locations and names

header [int or list of ints, default `'infer'`] Row number(s) to use as the column names, and the start of the data. Default behavior is to infer the column names: if no names are passed the behavior is identical to `header=0` and column names are inferred from the first line of the file, if column names are passed explicitly then the behavior is identical to `header=None`. Explicitly pass `header=0` to be able to replace existing names.

The header can be a list of ints that specify row locations for a MultiIndex on the columns e.g. `[0, 1, 3]`. Intervening rows that are not specified will be skipped (e.g. 2 in this example is skipped). Note that this parameter ignores commented lines and empty lines if `skip_blank_lines=True`, so `header=0` denotes the first line of data rather than the first line of the file.

names [array-like, default `None`] List of column names to use. If file contains no header row, then you should explicitly pass `header=None`. Duplicates in this list are not allowed.

index_col [int, str, sequence of int / str, or `False`, default `None`] Column(s) to use as the row labels of the DataFrame, either given as string name or column index. If a sequence of int / str is given, a MultiIndex is used.

Note: `index_col=False` can be used to force pandas to *not* use the first column as the index, e.g. when you have a malformed file with delimiters at the end of each line.

usecols [list-like or callable, default `None`] Return a subset of the columns. If list-like, all elements must either be positional (i.e. integer indices into the document columns) or strings that correspond to column names provided either by the user in `names` or inferred from the document header row(s). For example, a valid list-like `usecols` parameter would be `[0, 1, 2]` or `['foo', 'bar', 'baz']`.

Element order is ignored, so `usecols=[0, 1]` is the same as `[1, 0]`. To instantiate a DataFrame from data with element order preserved use `pd.read_csv(data, usecols=['foo', 'bar'])[['foo', 'bar']]` for columns in `['foo', 'bar']` order or `pd.read_csv(data, usecols=['foo', 'bar'])[['bar', 'foo']]` for `['bar', 'foo']` order.

If callable, the callable function will be evaluated against the column names, returning names where the callable function evaluates to True:

```
In [1]: import pandas as pd
In [2]: from io import StringIO
In [3]: data = ('col1,col2,col3\n'
   ....:         'a,b,1\n'
   ....:         'a,b,2\n'
   ....:         'c,d,3')
   ....:

In [4]: pd.read_csv(StringIO(data))
Out[4]:
   col1  col2  col3
0     a      b      1
1     a      b      2
2     c      d      3

In [5]: pd.read_csv(StringIO(data), usecols=lambda x: x.upper() in ['COL1', 'COL3'])
Out[5]:
   col1  col3
0     a      1
1     a      2
2     c      3
```

Using this parameter results in much faster parsing time and lower memory usage.

squeeze [boolean, default `False`] If the parsed data only contains one column then return a Series.

prefix [str, default `None`] Prefix to add to column numbers when no header, e.g. ‘X’ for X0, X1, ...

mangle_dupe_cols [boolean, default `True`] Duplicate columns will be specified as ‘X’, ‘X.1’... ‘X.N’, rather than ‘X’... ‘X’. Passing in `False` will cause data to be overwritten if there are duplicate names in the columns.

General parsing configuration

dtype [Type name or dict of column -> type, default `None`] Data type for data or columns. E.g. `{'a': np.float64, 'b': np.int32}` (unsupported with `engine='python'`). Use `str` or `object` together with suitable `na_values` settings to preserve and not interpret `dtype`.

engine [{‘c’, ‘python’}] Parser engine to use. The C engine is faster while the Python engine is currently more feature-complete.

converters [dict, default `None`] Dict of functions for converting values in certain columns. Keys can either be integers or column labels.

true_values [list, default `None`] Values to consider as `True`.

false_values [list, default `None`] Values to consider as `False`.

skipinitialspace [boolean, default `False`] Skip spaces after delimiter.

skiprows [list-like or integer, default None] Line numbers to skip (0-indexed) or number of lines to skip (int) at the start of the file.

If callable, the callable function will be evaluated against the row indices, returning True if the row should be skipped and False otherwise:

```
In [6]: data = ('col1,col2,col3\n'...:     'a,b,1\n'...:     'a,b,2\n'...:     'c,d,3')...:

In [7]: pd.read_csv(StringIO(data))
Out[7]:
   col1  col2  col3
0     a     b     1
1     a     b     2
2     c     d     3

In [8]: pd.read_csv(StringIO(data), skiprows=lambda x: x % 2 != 0)
Out[8]:
   col1  col2  col3
0     a     b     2
```

skipfooter [int, default 0] Number of lines at bottom of file to skip (unsupported with engine='c').

nrows [int, default None] Number of rows of file to read. Useful for reading pieces of large files.

low_memory [boolean, default True] Internally process the file in chunks, resulting in lower memory use while parsing, but possibly mixed type inference. To ensure no mixed types either set False, or specify the type with the `dtype` parameter. Note that the entire file is read into a single `DataFrame` regardless, use the `chunksize` or `iterator` parameter to return the data in chunks. (Only valid with C parser)

memory_map [boolean, default False] If a filepath is provided for `filepath_or_buffer`, map the file object directly onto memory and access the data directly from there. Using this option can improve performance because there is no longer any I/O overhead.

NA and missing data handling

na_values [scalar, str, list-like, or dict, default None] Additional strings to recognize as NA/NaN. If dict passed, specific per-column NA values. See [na values const](#) below for a list of the values interpreted as NaN by default.

keep_default_na [boolean, default True] Whether or not to include the default NaN values when parsing the data. Depending on whether `na_values` is passed in, the behavior is as follows:

- If `keep_default_na` is True, and `na_values` are specified, `na_values` is appended to the default NaN values used for parsing.
- If `keep_default_na` is True, and `na_values` are not specified, only the default NaN values are used for parsing.
- If `keep_default_na` is False, and `na_values` are specified, only the NaN values specified `na_values` are used for parsing.
- If `keep_default_na` is False, and `na_values` are not specified, no strings will be parsed as NaN.

Note that if `na_filter` is passed in as False, the `keep_default_na` and `na_values` parameters will be ignored.

na_filter [boolean, default True] Detect missing value markers (empty strings and the value of `na_values`). In data without any NAs, passing `na_filter=False` can improve the performance of reading a large file.

verbose [boolean, default False] Indicate number of NA values placed in non-numeric columns.

skip_blank_lines [boolean, default True] If True, skip over blank lines rather than interpreting as NaN values.

Datetime handling

parse_dates [boolean or list of ints or names or list of lists or dict, default False.]

- If True -> try parsing the index.
- If [1, 2, 3] -> try parsing columns 1, 2, 3 each as a separate date column.
- If [[1, 3]] -> combine columns 1 and 3 and parse as a single date column.
- If {'foo': [1, 3]} -> parse columns 1, 3 as date and call result ‘foo’. A fast-path exists for iso8601-formatted dates.

infer_datetime_format [boolean, default False] If True and parse_dates is enabled for a column, attempt to infer the datetime format to speed up the processing.

keep_date_col [boolean, default False] If True and parse_dates specifies combining multiple columns then keep the original columns.

date_parser [function, default None] Function to use for converting a sequence of string columns to an array of datetime instances. The default uses `dateutil.parser.parser` to do the conversion. pandas will try to call `date_parser` in three different ways, advancing to the next if an exception occurs: 1) Pass one or more arrays (as defined by `parse_dates`) as arguments; 2) concatenate (row-wise) the string values from the columns defined by `parse_dates` into a single array and pass that; and 3) call `date_parser` once for each row using one or more strings (corresponding to the columns defined by `parse_dates`) as arguments.

dayfirst [boolean, default False] DD/MM format dates, international and European format.

cache_dates [boolean, default True] If True, use a cache of unique, converted dates to apply the datetime conversion. May produce significant speed-up when parsing duplicate date strings, especially ones with timezone offsets.

New in version 0.25.0.

Iteration

iterator [boolean, default False] Return `TextFileReader` object for iteration or getting chunks with `get_chunk()`.

chunksize [int, default None] Return `TextFileReader` object for iteration. See [iterating and chunking](#) below.

Quoting, compression, and file format

compression [{‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}, default ‘infer’] For on-the-fly decompression of on-disk data. If ‘infer’, then use gzip, bz2, zip, or xz if `filepath_or_buffer` is a string ending in ‘.gz’, ‘.bz2’, ‘.zip’, or ‘.xz’, respectively, and no decompression otherwise. If using ‘zip’, the ZIP file must contain only one data file to be read in. Set to None for no decompression.

Changed in version 0.24.0: ‘infer’ option added and set to default.

thousands [str, default None] Thousands separator.

decimal [str, default ‘.’] Character to recognize as decimal point. E.g. use ‘,’ for European data.

float_precision [string, default None] Specifies which converter the C engine should use for floating-point values. The options are `None` for the ordinary converter, `high` for the high-precision converter, and `round_trip` for the round-trip converter.

lineterminator [str (length 1), default None] Character to break file into lines. Only valid with C parser.

quotechar [str (length 1)] The character used to denote the start and end of a quoted item. Quoted items can include the delimiter and it will be ignored.

quoting [int or `csv.QUOTE_*` instance, default 0] Control field quoting behavior per `csv.QUOTE_*` constants. Use one of `QUOTE_MINIMAL` (0), `QUOTE_ALL` (1), `QUOTE_NONNUMERIC` (2) or `QUOTE_NONE` (3).

doublequote [boolean, default True] When `quotechar` is specified and `quoting` is not `QUOTE_NONE`, indicate whether or not to interpret two consecutive `quotechar` elements **inside** a field as a single `quotechar` element.

escapechar [str (length 1), default None] One-character string used to escape delimiter when `quoting` is `QUOTE_NONE`.

comment [str, default None] Indicates remainder of line should not be parsed. If found at the beginning of a line, the line will be ignored altogether. This parameter must be a single character. Like empty lines (as long as `skip_blank_lines=True`), fully commented lines are ignored by the parameter `header` but not by `skiprows`. For example, if `comment='#'`, parsing '#empty\na,b,c\n1,2,3' with `header=0` will result in 'a,b,c' being treated as the header.

encoding [str, default None] Encoding to use for UTF when reading/writing (e.g. 'utf-8'). [List of Python standard encodings](#).

dialect [str or `csv.Dialect` instance, default None] If provided, this parameter will override values (default or not) for the following parameters: `delimiter`, `doublequote`, `escapechar`, `skipinitialspace`, `quotechar`, and `quoting`. If it is necessary to override values, a `ParserWarning` will be issued. See `csv.Dialect` documentation for more details.

Error handling

error_bad_lines [boolean, default True] Lines with too many fields (e.g. a csv line with too many commas) will by default cause an exception to be raised, and no `DataFrame` will be returned. If `False`, then these “bad lines” will be dropped from the `DataFrame` that is returned. See [bad lines](#) below.

warn_bad_lines [boolean, default True] If `error_bad_lines` is `False`, and `warn_bad_lines` is `True`, a warning for each “bad line” will be output.

Specifying column data types

You can indicate the data type for the whole `DataFrame` or individual columns:

```
In [9]: import numpy as np

In [10]: data = ('a,b,c,d\n'
.....:      '1,2,3,4\n'
.....:      '5,6,7,8\n'
.....:      '9,10,11')
.....:

In [11]: print(data)
a,b,c,d
1,2,3,4
5,6,7,8
9,10,11

In [12]: df = pd.read_csv(StringIO(data), dtype=object)
```

(continues on next page)

(continued from previous page)

```
In [13]: df
Out[13]:
   a    b    c    d
0  1    2    3    4
1  5    6    7    8
2  9   10   11   NaN

In [14]: df['a'][0]
Out[14]: '1'

In [15]: df = pd.read_csv(StringIO(data),
....:                  dtype={'b': object, 'c': np.float64, 'd': 'Int64'})
....:

In [16]: df.dtypes
Out[16]:
a      int64
b      object
c    float64
d      Int64
dtype: object
```

Fortunately, pandas offers more than one way to ensure that your column(s) contain only one `dtype`. If you're unfamiliar with these concepts, you can see [here](#) to learn more about `dtypes`, and [here](#) to learn more about `object` conversion in pandas.

For instance, you can use the `converters` argument of `read_csv()`:

```
In [17]: data = ("col_1\n"
....:           "1\n"
....:           "2\n"
....:           "'A'\n"
....:           "4.22")
....:

In [18]: df = pd.read_csv(StringIO(data), converters={'col_1': str})

In [19]: df
Out[19]:
  col_1
0      1
1      2
2      'A'
3     4.22

In [20]: df['col_1'].apply(type).value_counts()
Out[20]:
<class 'str'>    4
Name: col_1, dtype: int64
```

Or you can use the `to_numeric()` function to coerce the `dtypes` after reading the data,

```
In [21]: df2 = pd.read_csv(StringIO(data))

In [22]: df2['col_1'] = pd.to_numeric(df2['col_1'], errors='coerce')
```

(continues on next page)

(continued from previous page)

```
In [23]: df2
Out[23]:
   col_1
0    1.00
1    2.00
2    NaN
3    4.22

In [24]: df2['col_1'].apply(type).value_counts()
Out[24]:
<class 'float'>    4
Name: col_1, dtype: int64
```

which will convert all valid parsing to floats, leaving the invalid parsing as NaN.

Ultimately, how you deal with reading in columns containing mixed dtypes depends on your specific needs. In the case above, if you wanted to NaN out the data anomalies, then `to_numeric()` is probably your best option. However, if you wanted for all the data to be coerced, no matter the type, then using the `converters` argument of `read_csv()` would certainly be worth trying.

Note: In some cases, reading in abnormal data with columns containing mixed dtypes will result in an inconsistent dataset. If you rely on pandas to infer the dtypes of your columns, the parsing engine will go and infer the dtypes for different chunks of the data, rather than the whole dataset at once. Consequently, you can end up with column(s) with mixed dtypes. For example,

```
In [25]: col_1 = list(range(500000)) + ['a', 'b'] + list(range(500000))

In [26]: df = pd.DataFrame({'col_1': col_1})

In [27]: df.to_csv('foo.csv')

In [28]: mixed_df = pd.read_csv('foo.csv')

In [29]: mixed_df['col_1'].apply(type).value_counts()
Out[29]:
<class 'int'>    737858
<class 'str'>    262144
Name: col_1, dtype: int64

In [30]: mixed_df['col_1'].dtype
Out[30]: dtype('O')
```

will result with `mixed_df` containing an `int` dtype for certain chunks of the column, and `str` for others due to the mixed dtypes from the data that was read in. It is important to note that the overall column will be marked with a dtype of `object`, which is used for columns with mixed dtypes.

Specifying categorical dtype

Categorical columns can be parsed directly by specifying `dtype='category'` or `dtype=CategoricalDtype(categories, ordered)`.

```
In [31]: data = ('col1,col2,col3\n'
....:             'a,b,1\n'
....:             'a,b,2\n'
....:             'c,d,3')
....:

In [32]: pd.read_csv(StringIO(data))
Out[32]:
   col1  col2  col3
0     a     b     1
1     a     b     2
2     c     d     3

In [33]: pd.read_csv(StringIO(data)).dtypes
Out[33]:
col1    object
col2    object
col3    int64
dtype: object

In [34]: pd.read_csv(StringIO(data), dtype='category').dtypes
Out[34]:
col1    category
col2    category
col3    category
dtype: object
```

Individual columns can be parsed as a Categorical using a dict specification:

```
In [35]: pd.read_csv(StringIO(data), dtype={'col1': 'category'}).dtypes
Out[35]:
col1    category
col2    object
col3    int64
dtype: object
```

New in version 0.21.0.

Specifying `dtype='category'` will result in an unordered Categorical whose categories are the unique values observed in the data. For more control on the categories and order, create a `CategoricalDtype` ahead of time, and pass that for that column's `dtype`.

```
In [36]: from pandas.api.types import CategoricalDtype

In [37]: dtype = CategoricalDtype(['d', 'c', 'b', 'a'], ordered=True)

In [38]: pd.read_csv(StringIO(data), dtype={'col1': dtype}).dtypes
Out[38]:
col1    category
col2    object
col3    int64
dtype: object
```

When using `dtype=CategoricalDtype`, “unexpected” values outside of `dtype.categories` are treated as missing values.

```
In [39]: dtype = CategoricalDtype(['a', 'b', 'd']) # No 'c'

In [40]: pd.read_csv(StringIO(data), dtype={'col1': dtype}).col1
Out[40]:
0      a
1      a
2    NaN
Name: col1, dtype: category
Categories (3, object): [a, b, d]
```

This matches the behavior of `Categorical.set_categories()`.

Note: With `dtype='category'`, the resulting categories will always be parsed as strings (object dtype). If the categories are numeric they can be converted using the `to_numeric()` function, or as appropriate, another converter such as `to_datetime()`.

When `dtype` is a `CategoricalDtype` with homogeneous `categories` (all numeric, all datetimes, etc.), the conversion is done automatically.

```
In [41]: df = pd.read_csv(StringIO(data), dtype='category')

In [42]: df.dtypes
Out[42]:
col1    category
col2    category
col3    category
dtype: object

In [43]: df['col3']
Out[43]:
0      1
1      2
2      3
Name: col3, dtype: category
Categories (3, object): [1, 2, 3]

In [44]: df['col3'].cat.categories = pd.to_numeric(df['col3'].cat.categories)

In [45]: df['col3']
Out[45]:
0      1
1      2
2      3
Name: col3, dtype: category
Categories (3, int64): [1, 2, 3]
```

Naming and using columns

Handling column names

A file may or may not have a header row. pandas assumes the first row should be used as the column names:

```
In [46]: data = ('a,b,c\n'
....:      '1,2,3\n'
....:      '4,5,6\n'
....:      '7,8,9')
....:

In [47]: print(data)
a,b,c
1,2,3
4,5,6
7,8,9

In [48]: pd.read_csv(StringIO(data))
Out[48]:
   a   b   c
0  1  2  3
1  4  5  6
2  7  8  9
```

By specifying the `names` argument in conjunction with `header` you can indicate other names to use and whether or not to throw away the header row (if any):

```
In [49]: print(data)
a,b,c
1,2,3
4,5,6
7,8,9

In [50]: pd.read_csv(StringIO(data), names=['foo', 'bar', 'baz'], header=0)
Out[50]:
   foo   bar   baz
0    1     2     3
1    4     5     6
2    7     8     9

In [51]: pd.read_csv(StringIO(data), names=['foo', 'bar', 'baz'], header=None)
Out[51]:
   foo   bar   baz
0    a     b     c
1    1     2     3
2    4     5     6
3    7     8     9
```

If the header is in a row other than the first, pass the row number to `header`. This will skip the preceding rows:

```
In [52]: data = ('skip this skip it\n'
....:      'a,b,c\n'
....:      '1,2,3\n'
....:      '4,5,6\n'
....:      '7,8,9')
....:
```

(continues on next page)

(continued from previous page)

```
In [53]: pd.read_csv(StringIO(data), header=1)
Out[53]:
   a   b   c
0  1   2   3
1  4   5   6
2  7   8   9
```

Note: Default behavior is to infer the column names: if no names are passed the behavior is identical to `header=0` and column names are inferred from the first non-blank line of the file, if column names are passed explicitly then the behavior is identical to `header=None`.

Duplicate names parsing

If the file or header contains duplicate names, pandas will by default distinguish between them so as to prevent overwriting data:

```
In [54]: data = ('a,b,a\n'
....:           '0,1,2\n'
....:           '3,4,5')
....:

In [55]: pd.read_csv(StringIO(data))
Out[55]:
   a   b   a.1
0  0   1   2
1  3   4   5
```

There is no more duplicate data because `mangle_dupe_cols=True` by default, which modifies a series of duplicate columns ‘X’, …, ‘X’ to become ‘X’, ‘X.1’, …, ‘X.N’. If `mangle_dupe_cols=False`, duplicate data can arise:

```
In [2]: data = 'a,b,a\n0,1,2\n3,4,5'
In [3]: pd.read_csv(StringIO(data), mangle_dupe_cols=False)
Out[3]:
   a   b   a
0  2   1   2
1  5   4   5
```

To prevent users from encountering this problem with duplicate data, a `ValueError` exception is raised if `mangle_dupe_cols != True`:

```
In [2]: data = 'a,b,a\n0,1,2\n3,4,5'
In [3]: pd.read_csv(StringIO(data), mangle_dupe_cols=False)
...
ValueError: Setting mangle_dupe_cols=False is not supported yet
```

Filtering columns (usecols)

The `usecols` argument allows you to select any subset of the columns in a file, either using the column names, position numbers or a callable:

```
In [56]: data = 'a,b,c,d\n1,2,3,foo\n4,5,6,bar\n7,8,9,baz'

In [57]: pd.read_csv(StringIO(data))
Out[57]:
   a   b   c   d
0  1  2  3  foo
1  4  5  6  bar
2  7  8  9  baz

In [58]: pd.read_csv(StringIO(data), usecols=['b', 'd'])
Out[58]:
   b   d
0  2  foo
1  5  bar
2  8  baz

In [59]: pd.read_csv(StringIO(data), usecols=[0, 2, 3])
Out[59]:
   a   c   d
0  1  3  foo
1  4  6  bar
2  7  9  baz

In [60]: pd.read_csv(StringIO(data), usecols=lambda x: x.upper() in ['A', 'C'])
Out[60]:
   a   c
0  1  3
1  4  6
2  7  9
```

The `usecols` argument can also be used to specify which columns not to use in the final result:

```
In [61]: pd.read_csv(StringIO(data), usecols=lambda x: x not in ['a', 'c'])
Out[61]:
   b   d
0  2  foo
1  5  bar
2  8  baz
```

In this case, the callable is specifying that we exclude the “a” and “c” columns from the output.

Comments and empty lines

Ignoring line comments and empty lines

If the `comment` parameter is specified, then completely commented lines will be ignored. By default, completely blank lines will be ignored as well.

```
In [62]: data = ('\n'
.....:      'a,b,c\n'
.....:      '\n'
```

(continues on next page)

(continued from previous page)

```

....:     '# commented line\n'
....:     '1,2,3\n'
....:     '\n'
....:     '4,5,6')
....:

In [63]: print(data)

a,b,c

# commented line
1,2,3

4,5,6

In [64]: pd.read_csv(StringIO(data), comment='#')
Out[64]:
   a   b   c
0  1   2   3
1  4   5   6

```

If `skip_blank_lines=False`, then `read_csv` will not ignore blank lines:

```

In [65]: data = ('a,b,c\n'
....:         '\n'
....:         '1,2,3\n'
....:         '\n'
....:         '\n'
....:         '4,5,6')
....:

In [66]: pd.read_csv(StringIO(data), skip_blank_lines=False)
Out[66]:
      a      b      c
0  NaN    NaN    NaN
1  1.0    2.0    3.0
2  NaN    NaN    NaN
3  NaN    NaN    NaN
4  4.0    5.0    6.0

```

Warning: The presence of ignored lines might create ambiguities involving line numbers; the parameter `header` uses row numbers (ignoring commented/empty lines), while `skiprows` uses line numbers (including commented/empty lines):

```

In [67]: data = ('#comment\n'
....:         'a,b,c\n'
....:         'A,B,C\n'
....:         '1,2,3')
....:

In [68]: pd.read_csv(StringIO(data), comment='#', header=1)
Out[68]:
   A   B   C
0  1   2   3

In [69]: data = ('A,B,C\n'

```

```

....:      '#comment\n'
....:      'a,b,c\n'
....:      '1,2,3')
....:

In [70]: pd.read_csv(StringIO(data), comment='#', skiprows=2)
Out[70]:
   a   b   c
0   1   2   3

```

If both header and skiprows are specified, header will be relative to the end of skiprows. For example:

```

In [71]: data = ('# empty\n'
....:      '# second empty line\n'
....:      '# third emptyline\n'
....:      'X,Y,Z\n'
....:      '1,2,3\n'
....:      'A,B,C\n'
....:      '1,2.,4.\n'
....:      '5.,NaN,10.0\n')
....:

In [72]: print(data)
# empty
# second empty line
# third emptyline
X,Y,Z
1,2,3
A,B,C
1,2.,4.
5.,NaN,10.0

In [73]: pd.read_csv(StringIO(data), comment='#', skiprows=4, header=1)
Out[73]:
     A      B      C
0  1.0    2.0    4.0
1  5.0    NaN   10.0

```

Comments

Sometimes comments or meta data may be included in a file:

```

In [74]: print(open('tmp.csv').read())
ID,level,category
Patient1,123000,x # really unpleasant
Patient2,23000,y # wouldn't take his medicine
Patient3,1234018,z # awesome

```

By default, the parser includes the comments in the output:

```

In [75]: df = pd.read_csv('tmp.csv')

In [76]: df

```

(continues on next page)

(continued from previous page)

Out[76]:

```
ID      level          category
0 Patient1    123000      x # really unpleasant
1 Patient2    23000       y # wouldn't take his medicine
2 Patient3    1234018     z # awesome
```

We can suppress the comments using the `comment` keyword:

In [77]: `df = pd.read_csv('tmp.csv', comment='#')`

In [78]: `df`

Out[78]:

```
ID      level  category
0 Patient1    123000      x
1 Patient2    23000       y
2 Patient3    1234018     z
```

Dealing with Unicode data

The `encoding` argument should be used for encoded unicode data, which will result in byte strings being decoded to unicode in the result:

In [79]: `from io import BytesIO`

In [80]: `data = (b'word,length\n'....: b'Tr\xc3\xa4umen,7\n'....: b'Gr\xc3\xbc\xc3\x9fe,5')....:`

In [81]: `data = data.decode('utf8').encode('latin-1')`

In [82]: `df = pd.read_csv(BytesIO(data), encoding='latin-1')`

In [83]: `df`

Out[83]:

```
word  length
0 Träumen      7
1 Grüße        5
```

In [84]: `df['word'][1]`

Out[84]: 'Grüße'

Some formats which encode all characters as multiple bytes, like UTF-16, won't parse correctly at all without specifying the encoding. [Full list of Python standard encodings](#).

Index columns and trailing delimiters

If a file has one more column of data than the number of column names, the first column will be used as the DataFrame's row names:

```
In [85]: data = ('a,b,c\n'
....:           '4,apple,bat,5.7\n'
....:           '8,orange,cow,10')
....:

In [86]: pd.read_csv(StringIO(data))
Out[86]:
      a      b      c
4   apple   bat    5.7
8  orange   cow   10.0
```

```
In [87]: data = ('index,a,b,c\n'
....:           '4,apple,bat,5.7\n'
....:           '8,orange,cow,10')
....:

In [88]: pd.read_csv(StringIO(data), index_col=0)
Out[88]:
      a      b      c
index
4       apple   bat    5.7
8      orange   cow   10.0
```

Ordinarily, you can achieve this behavior using the `index_col` option.

There are some exception cases when a file has been prepared with delimiters at the end of each data line, confusing the parser. To explicitly disable the index column inference and discard the last column, pass `index_col=False`:

```
In [89]: data = ('a,b,c\n'
....:           '4,apple,bat,\n'
....:           '8,orange,cow,')
....:

In [90]: print(data)
a,b,c
4,apple,bat,
8,orange,cow,

In [91]: pd.read_csv(StringIO(data))
Out[91]:
      a      b      c
4   apple   bat   NaN
8  orange   cow   NaN

In [92]: pd.read_csv(StringIO(data), index_col=False)
Out[92]:
      a      b      c
0   4   apple   bat
1   8  orange   cow
```

If a subset of data is being parsed using the `usecols` option, the `index_col` specification is based on that subset, not the original data.

```
In [93]: data = ('a,b,c\n'
.....      '4,apple,bat,\n'
.....      '8,orange,cow,')
.....  
  
In [94]: print(data)
a,b,c
4,apple,bat,
8,orange,cow,  
  
In [95]: pd.read_csv(StringIO(data), usecols=['b', 'c'])
Out[95]:
     b    c
4   bat  NaN
8   cow  NaN  
  
In [96]: pd.read_csv(StringIO(data), usecols=['b', 'c'], index_col=0)
Out[96]:
     b    c
4   bat  NaN
8   cow  NaN
```

Date Handling

Specifying date columns

To better facilitate working with datetime data, `read_csv()` uses the keyword arguments `parse_dates` and `date_parser` to allow users to specify a variety of columns and date/time formats to turn the input text data into datetime objects.

The simplest case is to just pass in `parse_dates=True`:

```
# Use a column as an index, and parse it as dates.
In [97]: df = pd.read_csv('foo.csv', index_col=0, parse_dates=True)  
  
In [98]: df
Out[98]:
       A   B   C
date
2009-01-01  a   1   2
2009-01-02  b   3   4
2009-01-03  c   4   5  
  
# These are Python datetime objects
In [99]: df.index
Out[99]: DatetimeIndex(['2009-01-01', '2009-01-02', '2009-01-03'], dtype=
->'datetime64[ns]', name='date', freq=None)
```

It is often the case that we may want to store date and time data separately, or store various date fields separately. the `parse_dates` keyword can be used to specify a combination of columns to parse the dates and/or times from.

You can specify a list of column lists to `parse_dates`, the resulting date columns will be prepended to the output (so as to not affect the existing column order) and the new column names will be the concatenation of the component column names:

```
In [100]: print(open('tmp.csv').read())
KORD,19990127, 19:00:00, 18:56:00, 0.8100
KORD,19990127, 20:00:00, 19:56:00, 0.0100
KORD,19990127, 21:00:00, 20:56:00, -0.5900
KORD,19990127, 21:00:00, 21:18:00, -0.9900
KORD,19990127, 22:00:00, 21:56:00, -0.5900
KORD,19990127, 23:00:00, 22:56:00, -0.5900

In [101]: df = pd.read_csv('tmp.csv', header=None, parse_dates=[[1, 2], [1, 3]])

In [102]: df
Out[102]:
      1_2          1_3    0    4
0 1999-01-27 19:00:00 1999-01-27 18:56:00  KORD  0.81
1 1999-01-27 20:00:00 1999-01-27 19:56:00  KORD  0.01
2 1999-01-27 21:00:00 1999-01-27 20:56:00  KORD -0.59
3 1999-01-27 21:00:00 1999-01-27 21:18:00  KORD -0.99
4 1999-01-27 22:00:00 1999-01-27 21:56:00  KORD -0.59
5 1999-01-27 23:00:00 1999-01-27 22:56:00  KORD -0.59
```

By default the parser removes the component date columns, but you can choose to retain them via the `keep_date_col` keyword:

```
In [103]: df = pd.read_csv('tmp.csv', header=None, parse_dates=[[1, 2], [1, 3]],
.....:             keep_date_col=True)
.....:

In [104]: df
Out[104]:
      1_2          1_3    0    1    2    3    4
0 1999-01-27 19:00:00 1999-01-27 18:56:00  KORD 19990127 19:00:00 18:56:00  0.81
1 1999-01-27 20:00:00 1999-01-27 19:56:00  KORD 19990127 20:00:00 19:56:00  0.01
2 1999-01-27 21:00:00 1999-01-27 20:56:00  KORD 19990127 21:00:00 20:56:00 -0.59
3 1999-01-27 21:00:00 1999-01-27 21:18:00  KORD 19990127 21:00:00 21:18:00 -0.99
4 1999-01-27 22:00:00 1999-01-27 21:56:00  KORD 19990127 22:00:00 21:56:00 -0.59
5 1999-01-27 23:00:00 1999-01-27 22:56:00  KORD 19990127 23:00:00 22:56:00 -0.59
```

Note that if you wish to combine multiple columns into a single date column, a nested list must be used. In other words, `parse_dates=[1, 2]` indicates that the second and third columns should each be parsed as separate date columns while `parse_dates=[[1, 2]]` means the two columns should be parsed into a single column.

You can also use a dict to specify custom name columns:

```
In [105]: date_spec = {'nominal': [1, 2], 'actual': [1, 3]}

In [106]: df = pd.read_csv('tmp.csv', header=None, parse_dates=date_spec)

In [107]: df
Out[107]:
      nominal          actual    0    4
0 1999-01-27 19:00:00 1999-01-27 18:56:00  KORD  0.81
1 1999-01-27 20:00:00 1999-01-27 19:56:00  KORD  0.01
2 1999-01-27 21:00:00 1999-01-27 20:56:00  KORD -0.59
3 1999-01-27 21:00:00 1999-01-27 21:18:00  KORD -0.99
4 1999-01-27 22:00:00 1999-01-27 21:56:00  KORD -0.59
5 1999-01-27 23:00:00 1999-01-27 22:56:00  KORD -0.59
```

It is important to remember that if multiple text columns are to be parsed into a single date column, then a new column

is prepended to the data. The `index_col` specification is based off of this new set of columns rather than the original data columns:

```
In [108]: date_spec = {'nominal': [1, 2], 'actual': [1, 3]}

In [109]: df = pd.read_csv('tmp.csv', header=None, parse_dates=date_spec,
.....:                 index_col=0) # index is the nominal column
.....:

In [110]: df
Out[110]:
```

	nominal	actual	0	4
0	1999-01-27 19:00:00	1999-01-27 18:56:00	KORD	0.81
1	1999-01-27 20:00:00	1999-01-27 19:56:00	KORD	0.01
2	1999-01-27 21:00:00	1999-01-27 20:56:00	KORD	-0.59
3	1999-01-27 21:00:00	1999-01-27 21:18:00	KORD	-0.99
4	1999-01-27 22:00:00	1999-01-27 21:56:00	KORD	-0.59
5	1999-01-27 23:00:00	1999-01-27 22:56:00	KORD	-0.59

Note: If a column or index contains an unparsable date, the entire column or index will be returned unaltered as an object data type. For non-standard datetime parsing, use `to_datetime()` after `pd.read_csv`.

Note: `read_csv` has a fast_path for parsing datetime strings in iso8601 format, e.g “2000-01-01T00:01:02+00:00” and similar variations. If you can arrange for your data to store datetimes in this format, load times will be significantly faster, ~20x has been observed.

Note: When passing a dict as the `parse_dates` argument, the order of the columns prepended is not guaranteed, because `dict` objects do not impose an ordering on their keys. On Python 2.7+ you may use `collections.OrderedDict` instead of a regular `dict` if this matters to you. Because of this, when using a dict for ‘`parse_dates`’ in conjunction with the `index_col` argument, it’s best to specify `index_col` as a column label rather than as an index on the resulting frame.

Date parsing functions

Finally, the parser allows you to specify a custom `date_parser` function to take full advantage of the flexibility of the date parsing API:

```
In [111]: df = pd.read_csv('tmp.csv', header=None, parse_dates=date_spec,
.....:                 date_parser=pd.io.date_converters.parse_date_time)
.....:

In [112]: df
Out[112]:
```

	nominal	actual	0	4
0	1999-01-27 19:00:00	1999-01-27 18:56:00	KORD	0.81
1	1999-01-27 20:00:00	1999-01-27 19:56:00	KORD	0.01
2	1999-01-27 21:00:00	1999-01-27 20:56:00	KORD	-0.59
3	1999-01-27 21:00:00	1999-01-27 21:18:00	KORD	-0.99
4	1999-01-27 22:00:00	1999-01-27 21:56:00	KORD	-0.59
5	1999-01-27 23:00:00	1999-01-27 22:56:00	KORD	-0.59

Pandas will try to call the `date_parser` function in three different ways. If an exception is raised, the next one is tried:

1. `date_parser` is first called with one or more arrays as arguments, as defined using `parse_dates` (e.g., `date_parser(['2013', '2013'], ['1', '2'])`).
2. If #1 fails, `date_parser` is called with all the columns concatenated row-wise into a single array (e.g., `date_parser(['2013 1', '2013 2'])`).
3. If #2 fails, `date_parser` is called once for every row with one or more string arguments from the columns indicated with `parse_dates` (e.g., `date_parser('2013', '1')` for the first row, `date_parser('2013', '2')` for the second, etc.).

Note that performance-wise, you should try these methods of parsing dates in order:

1. Try to infer the format using `infer_datetime_format=True` (see section below).
2. If you know the format, use `pd.to_datetime(): date_parser=lambda x: pd.to_datetime(x, format=...)`.
3. If you have a really non-standard format, use a custom `date_parser` function. For optimal performance, this should be vectorized, i.e., it should accept arrays as arguments.

You can explore the date parsing functionality in `date_converters.py` and add your own. We would love to turn this module into a community supported set of date/time parsers. To get you started, `date_converters.py` contains functions to parse dual date and time columns, year/month/day columns, and year/month/day/hour/minute/second columns. It also contains a `generic_parser` function so you can curry it with a function that deals with a single date rather than the entire array.

Parsing a CSV with mixed timezones

Pandas cannot natively represent a column or index with mixed timezones. If your CSV file contains columns with a mixture of timezones, the default result will be an object-dtype column with strings, even with `parse_dates`.

```
In [113]: content = """\n.....: a\n.....: 2000-01-01T00:00:00+05:00\n.....: 2000-01-01T00:00:00+06:00"""\n.....:\n\nIn [114]: df = pd.read_csv(StringIO(content), parse_dates=['a'])\n\nIn [115]: df['a']\nOut[115]:\n0    2000-01-01 00:00:00+05:00\n1    2000-01-01 00:00:00+06:00\nName: a, dtype: object
```

To parse the mixed-timezone values as a datetime column, pass a partially-applied `to_datetime()` with `utc=True` as the `date_parser`.

```
In [116]: df = pd.read_csv(StringIO(content), parse_dates=['a'],\n.....:                     date_parser=lambda col: pd.to_datetime(col, utc=True))\n.....:\n\nIn [117]: df['a']\nOut[117]:\n0    1999-12-31 19:00:00+00:00
```

(continues on next page)

(continued from previous page)

```
1 1999-12-31 18:00:00+00:00
Name: a, dtype: datetime64[ns, UTC]
```

Inferring datetime format

If you have `parse_dates` enabled for some or all of your columns, and your datetime strings are all formatted the same way, you may get a large speed up by setting `infer_datetime_format=True`. If set, pandas will attempt to guess the format of your datetime strings, and then use a faster means of parsing the strings. 5-10x parsing speeds have been observed. pandas will fallback to the usual parsing if either the format cannot be guessed or the format that was guessed cannot properly parse the entire column of strings. So in general, `infer_datetime_format` should not have any negative consequences if enabled.

Here are some examples of datetime strings that can be guessed (All representing December 30th, 2011 at 00:00:00):

- “20111230”
- “2011/12/30”
- “20111230 00:00:00”
- “12/30/2011 00:00:00”
- “30/Dec/2011 00:00:00”
- “30/December/2011 00:00:00”

Note that `infer_datetime_format` is sensitive to `dayfirst=True`. With `dayfirst=True`, it will guess “01/12/2011” to be December 1st. With `dayfirst=False` (default) it will guess “01/12/2011” to be January 12th.

```
# Try to infer the format for the index column
In [118]: df = pd.read_csv('foo.csv', index_col=0, parse_dates=True,
.....:                     infer_datetime_format=True)
.....:

In [119]: df
Out[119]:
      A   B   C
date
2009-01-01  a   1   2
2009-01-02  b   3   4
2009-01-03  c   4   5
```

International date formats

While US date formats tend to be MM/DD/YYYY, many international formats use DD/MM/YYYY instead. For convenience, a `dayfirst` keyword is provided:

```
In [120]: print(open('tmp.csv').read())
date,value,cat
1/6/2000,5,a
2/6/2000,10,b
3/6/2000,15,c

In [121]: pd.read_csv('tmp.csv', parse_dates=[0])
```

(continues on next page)

(continued from previous page)

```
Out[121]:
      date  value  cat
0 2000-01-06      5    a
1 2000-02-06     10    b
2 2000-03-06     15    c

In [122]: pd.read_csv('tmp.csv', dayfirst=True, parse_dates=[0])
Out[122]:
      date  value  cat
0 2000-06-01      5    a
1 2000-06-02     10    b
2 2000-06-03     15    c
```

Specifying method for floating-point conversion

The parameter `float_precision` can be specified in order to use a specific floating-point converter during parsing with the C engine. The options are the ordinary converter, the high-precision converter, and the round-trip converter (which is guaranteed to round-trip values after writing to a file). For example:

```
In [123]: val = '0.3066101993807095471566981359501369297504425048828125'

In [124]: data = 'a,b,c\n1,2,{0}'.format(val)

In [125]: abs(pd.read_csv(StringIO(data), engine='c',
.....:                      float_precision=None) ['c'][0] - float(val))
.....:
Out[125]: 1.1102230246251565e-16

In [126]: abs(pd.read_csv(StringIO(data), engine='c',
.....:                      float_precision='high') ['c'][0] - float(val))
.....:
Out[126]: 5.551115123125783e-17

In [127]: abs(pd.read_csv(StringIO(data), engine='c',
.....:                      float_precision='round_trip') ['c'][0] - float(val))
.....:
Out[127]: 0.0
```

Thousand separators

For large numbers that have been written with a thousands separator, you can set the `thousands` keyword to a string of length 1 so that integers will be parsed correctly:

By default, numbers with a thousands separator will be parsed as strings:

```
In [128]: print(open('tmp.csv').read())
ID|level|category
Patient1|123,000|x
Patient2|23,000|y
Patient3|1,234,018|z

In [129]: df = pd.read_csv('tmp.csv', sep='|')

In [130]: df
```

(continues on next page)

(continued from previous page)

```
Out[130]:
```

	ID	level	category
0	Patient1	123,000	x
1	Patient2	23,000	y
2	Patient3	1,234,018	z

```
In [131]: df.level.dtype  
Out[131]: dtype('O')
```

The thousands keyword allows integers to be parsed correctly:

```
In [132]: print(open('tmp.csv').read())  
ID|level|category  
Patient1|123,000|x  
Patient2|23,000|y  
Patient3|1,234,018|z  
  
In [133]: df = pd.read_csv('tmp.csv', sep='|', thousands=',')  
  
In [134]: df  
Out[134]:
```

	ID	level	category
0	Patient1	123000	x
1	Patient2	23000	y
2	Patient3	1234018	z

```
In [135]: df.level.dtype  
Out[135]: dtype('int64')
```

NA values

To control which values are parsed as missing values (which are signified by NaN), specify a string in na_values. If you specify a list of strings, then all values in it are considered to be missing values. If you specify a number (a float, like 5.0 or an integer like 5), the corresponding equivalent values will also imply a missing value (in this case effectively [5.0, 5] are recognized as NaN).

To completely override the default values that are recognized as missing, specify keep_default_na=False.

The default NaN recognized values are `['-1.#IND', '1.#QNAN', '1.#IND', '-1.#QNAN', '#N/A', '#N/A', 'N/A', 'n/a', 'NA', '<NA>', '#NA', 'NULL', 'null', 'NaN', '-NaN', 'nan', '-nan', '']`.

Let us consider some examples:

```
pd.read_csv('path_to_file.csv', na_values=[5])
```

In the example above 5 and 5.0 will be recognized as NaN, in addition to the defaults. A string will first be interpreted as a numerical 5, then as a NaN.

```
pd.read_csv('path_to_file.csv', keep_default_na=False, na_values=[''])
```

Above, only an empty field will be recognized as NaN.

```
pd.read_csv('path_to_file.csv', keep_default_na=False, na_values=["NA", "0"])
```

Above, both NA and 0 as strings are NaN.

```
pd.read_csv('path_to_file.csv', na_values=[ "Nope" ])
```

The default values, in addition to the string "Nope" are recognized as NaN.

Infinity

`inf` like values will be parsed as `np.inf` (positive infinity), and `-inf` as `-np.inf` (negative infinity). These will ignore the case of the value, meaning `Inf`, will also be parsed as `np.inf`.

Returning Series

Using the `squeeze` keyword, the parser will return output with a single column as a `Series`:

```
In [136]: print(open('tmp.csv').read())
level
Patient1,123000
Patient2,23000
Patient3,1234018

In [137]: output = pd.read_csv('tmp.csv', squeeze=True)

In [138]: output
Out[138]:
Patient1      123000
Patient2      23000
Patient3      1234018
Name: level, dtype: int64

In [139]: type(output)
Out[139]: pandas.core.series.Series
```

Boolean values

The common values `True`, `False`, `TRUE`, and `FALSE` are all recognized as boolean. Occasionally you might want to recognize other values as being boolean. To do this, use the `true_values` and `false_values` options as follows:

```
In [140]: data = ('a,b,c\n'
.....:      '1,Yes,2\n'
.....:      '3,No,4')
.....:

In [141]: print(data)
a,b,c
1,Yes,2
3,No,4

In [142]: pd.read_csv(StringIO(data))
Out[142]:
     a      b      c
0   1    Yes     2
1   3     No     4

In [143]: pd.read_csv(StringIO(data), true_values=['Yes'], false_values=['No'])
```

(continues on next page)

(continued from previous page)

```
Out[143]:
   a      b   c
0  1    True  2
1  3   False  4
```

Handling “bad” lines

Some files may have malformed lines with too few fields or too many. Lines with too few fields will have NA values filled in the trailing fields. Lines with too many fields will raise an error by default:

```
In [144]: data = ('a,b,c\n'
.....:           '1,2,3\n'
.....:           '4,5,6,7\n'
.....:           '8,9,10')
.....:

In [145]: pd.read_csv(StringIO(data))
-----
ParserError                                     Traceback (most recent call last)

    677
    678     parser_f.__name__ = name

/pandas/pandas/io/parsers.py in _read(filepath_or_buffer, kwds)
    452
    453     try:
--> 454         data = parser.read(nrows)
    455     finally:
    456         parser.close()

/pandas/pandas/io/parsers.py in read(self, nrows)
  1131     def read(self, nrows=None):
  1132         nrows = _validate_integer("nrows", nrows)
-> 1133         ret = self._engine.read(nrows)
  1134
  1135         # May alter columns / col_dict

/pandas/pandas/io/parsers.py in read(self, nrows)
  2035     def read(self, nrows=None):
  2036         try:
-> 2037             data = self._reader.read(nrows)
  2038         except StopIteration:
```

(continues on next page)

(continued from previous page)

```
2039         if self._first_chunk:

/pandas/_libs/parsers.pyx in pandas._libs.parsers.TextReader.read()

/pandas/_libs/parsers.pyx in pandas._libs.parsers.TextReader._read_low_memory()

/pandas/_libs/parsers.pyx in pandas._libs.parsers.TextReader._read_rows()

/pandas/_libs/parsers.pyx in pandas._libs.parsers.TextReader._tokenize_rows()

/pandas/_libs/parsers.pyx in pandas._libs.parsers.raise_parser_error()

ParserError: Error tokenizing data. C error: Expected 3 fields in line 3, saw 4
```

You can elect to skip bad lines:

```
In [29]: pd.read_csv(StringIO(data), error_bad_lines=False)
Skipping line 3: expected 3 fields, saw 4

Out[29]:
   a   b   c
0  1   2   3
1  8   9  10
```

You can also use the `usecols` parameter to eliminate extraneous column data that appear in some lines but not others:

```
In [30]: pd.read_csv(StringIO(data), usecols=[0, 1, 2])

Out[30]:
   a   b   c
0  1   2   3
1  4   5   6
2  8   9  10
```

Dialect

The `dialect` keyword gives greater flexibility in specifying the file format. By default it uses the Excel dialect but you can specify either the dialect name or a `csv.Dialect` instance.

Suppose you had data with unenclosed quotes:

```
In [146]: print(data)
label1,label2,label3
index1,"a,c,e
index2,b,d,f
```

By default, `read_csv` uses the Excel dialect and treats the double quote as the quote character, which causes it to fail when it finds a newline before it finds the closing double quote.

We can get around this using `dialect`:

```
In [147]: import csv

In [148]: dia = csv.excel()
```

(continues on next page)

(continued from previous page)

```
In [149]: dia.quoting = csv.QUOTE_NONE

In [150]: pd.read_csv(StringIO(data), dialect=dia)
Out[150]:
   label1  label2  label3
index1      "a        c        e
index2          b        d        f
```

All of the dialect options can be specified separately by keyword arguments:

```
In [151]: data = 'a,b,c~1,2,3~4,5,6'

In [152]: pd.read_csv(StringIO(data), lineterminator='~')
Out[152]:
   a  b  c
0  1  2  3
1  4  5  6
```

Another common dialect option is `skipinitialspace`, to skip any whitespace after a delimiter:

```
In [153]: data = 'a, b, c\n1, 2, 3\n4, 5, 6'

In [154]: print(data)
a, b, c
1, 2, 3
4, 5, 6

In [155]: pd.read_csv(StringIO(data), skipinitialspace=True)
Out[155]:
   a  b  c
0  1  2  3
1  4  5  6
```

The parsers make every attempt to “do the right thing” and not be fragile. Type inference is a pretty big deal. If a column can be coerced to integer dtype without altering the contents, the parser will do so. Any non-numeric columns will come through as object dtype as with the rest of pandas objects.

Quoting and Escape Characters

Quotes (and other escape characters) in embedded fields can be handled in any number of ways. One way is to use backslashes; to properly parse this data, you should pass the `escapechar` option:

```
In [156]: data = 'a,b\n"hello, \\"Bob\\\"", nice to see you",5'

In [157]: print(data)
a,b
"hello, \"Bob\"", nice to see you",5

In [158]: pd.read_csv(StringIO(data), escapechar='\\')
Out[158]:
           a  b
0  hello, "Bob", nice to see you  5
```

Files with fixed width columns

While `read_csv()` reads delimited data, the `read_fwf()` function works with data files that have known and fixed column widths. The function parameters to `read_fwf` are largely the same as `read_csv` with two extra parameters, and a different usage of the `delimiter` parameter:

- `colspeccs`: A list of pairs (tuples) giving the extents of the fixed-width fields of each line as half-open intervals (i.e., [from, to[). String value ‘infer’ can be used to instruct the parser to try detecting the column specifications from the first 100 rows of the data. Default behavior, if not specified, is to infer.
- `widths`: A list of field widths which can be used instead of ‘colspeccs’ if the intervals are contiguous.
- `delimiter`: Characters to consider as filler characters in the fixed-width file. Can be used to specify the filler character of the fields if it is not spaces (e.g., ‘~’).

Consider a typical fixed-width data file:

```
In [159]: print(open('bar.csv').read())
id8141    360.242940   149.910199   11950.7
id1594    444.953632   166.985655   11788.4
id1849    364.136849   183.628767   11806.2
id1230    413.836124   184.375703   11916.8
id1948    502.953953   173.237159   12468.3
```

In order to parse this file into a DataFrame, we simply need to supply the column specifications to the `read_fwf` function along with the file name:

```
# Column specifications are a list of half-intervals
In [160]: colspeccs = [(0, 6), (8, 20), (21, 33), (34, 43)]

In [161]: df = pd.read_fwf('bar.csv', colspeccs=colspeccs, header=None, index_col=0)

In [162]: df
Out[162]:
      1          2          3
0
id8141  360.242940  149.910199  11950.7
id1594  444.953632  166.985655  11788.4
id1849  364.136849  183.628767  11806.2
id1230  413.836124  184.375703  11916.8
id1948  502.953953  173.237159  12468.3
```

Note how the parser automatically picks column names X.<column number> when `header=None` argument is specified. Alternatively, you can supply just the column widths for contiguous columns:

```
# Widths are a list of integers
In [163]: widths = [6, 14, 13, 10]

In [164]: df = pd.read_fwf('bar.csv', widths=widths, header=None)

In [165]: df
Out[165]:
      0          1          2          3
0  id8141  360.242940  149.910199  11950.7
1  id1594  444.953632  166.985655  11788.4
2  id1849  364.136849  183.628767  11806.2
3  id1230  413.836124  184.375703  11916.8
4  id1948  502.953953  173.237159  12468.3
```

The parser will take care of extra white spaces around the columns so it's ok to have extra separation between the columns in the file.

By default, `read_fwf` will try to infer the file's `cols` by using the first 100 rows of the file. It can do it only in cases when the columns are aligned and correctly separated by the provided `delimiter` (default delimiter is whitespace).

```
In [166]: df = pd.read_fwf('bar.csv', header=None, index_col=0)

In [167]: df
Out[167]:
      1          2          3
0
id8141  360.242940  149.910199  11950.7
id1594  444.953632  166.985655  11788.4
id1849  364.136849  183.628767  11806.2
id1230  413.836124  184.375703  11916.8
id1948  502.953953  173.237159  12468.3
```

`read_fwf` supports the `dtype` parameter for specifying the types of parsed columns to be different from the inferred type.

```
In [168]: pd.read_fwf('bar.csv', header=None, index_col=0).dtypes
Out[168]:
1    float64
2    float64
3    float64
dtype: object

In [169]: pd.read_fwf('bar.csv', header=None, dtype={2: 'object'}).dtypes
Out[169]:
0    object
1    float64
2    object
3    float64
dtype: object
```

Indexes

Files with an “implicit” index column

Consider a file with one less entry in the header than the number of data column:

```
In [170]: print(open('foo.csv').read())
A,B,C
20090101,a,1,2
20090102,b,3,4
20090103,c,4,5
```

In this special case, `read_csv` assumes that the first column is to be used as the index of the DataFrame:

```
In [171]: pd.read_csv('foo.csv')
Out[171]:
      A   B   C
20090101  a   1   2
```

(continues on next page)

(continued from previous page)

20090102	b	3	4
20090103	c	4	5

Note that the dates weren't automatically parsed. In that case you would need to do as before:

```
In [172]: df = pd.read_csv('foo.csv', parse_dates=True)

In [173]: df.index
Out[173]: DatetimeIndex(['2009-01-01', '2009-01-02', '2009-01-03'], dtype='datetime64[ns]', freq=None)
```

Reading an index with a MultiIndex

Suppose you have data indexed by two columns:

```
In [174]: print(open('data/mindex_ex.csv').read())
year,indiv,zit,xit
1977, "A", 1.2,.6
1977, "B", 1.5,.5
1977, "C", 1.7,.8
1978, "A", .2,.06
1978, "B", .7,.2
1978, "C", .8,.3
1978, "D", .9,.5
1978, "E", 1.4,.9
1979, "C", .2,.15
1979, "D", .14,.05
1979, "E", .5,.15
1979, "F", 1.2,.5
1979, "G", 3.4,1.9
1979, "H", 5.4,2.7
1979, "I", 6.4,1.2
```

The `index_col` argument to `read_csv` can take a list of column numbers to turn multiple columns into a `MultiIndex` for the index of the returned object:

```
In [175]: df = pd.read_csv("data/mindex_ex.csv", index_col=[0, 1])

In [176]: df
Out[176]:
          zit    xit
year indiv
1977 A      1.20  0.60
      B      1.50  0.50
      C      1.70  0.80
1978 A      0.20  0.06
      B      0.70  0.20
      C      0.80  0.30
      D      0.90  0.50
      E      1.40  0.90
1979 C      0.20  0.15
      D      0.14  0.05
      E      0.50  0.15
      F      1.20  0.50
      G      3.40  1.90
```

(continues on next page)

(continued from previous page)

```
H      5.40  2.70
I      6.40  1.20

In [177]: df.loc[1978]
Out[177]:
      zit    xit
indiv
A      0.2   0.06
B      0.7   0.20
C      0.8   0.30
D      0.9   0.50
E      1.4   0.90
```

Reading columns with a MultiIndex

By specifying list of row locations for the header argument, you can read in a MultiIndex for the columns. Specifying non-consecutive rows will skip the intervening rows.

```
In [178]: from pandas._testing import makeCustomDataframe as mkdf

In [179]: df = mkdf(5, 3, r_idx_nlevels=2, c_idx_nlevels=4)

In [180]: df.to_csv('mi.csv')

In [181]: print(open('mi.csv').read())
C0,,C_10_g0,C_10_g1,C_10_g2
C1,,C_11_g0,C_11_g1,C_11_g2
C2,,C_12_g0,C_12_g1,C_12_g2
C3,,C_13_g0,C_13_g1,C_13_g2
R0,R1,,,
R_10_g0,R_11_g0,R0C0,R0C1,R0C2
R_10_g1,R_11_g1,R1C0,R1C1,R1C2
R_10_g2,R_11_g2,R2C0,R2C1,R2C2
R_10_g3,R_11_g3,R3C0,R3C1,R3C2
R_10_g4,R_11_g4,R4C0,R4C1,R4C2

In [182]: pd.read_csv('mi.csv', header=[0, 1, 2, 3], index_col=[0, 1])
Out[182]:
C0          C_10_g0  C_10_g1  C_10_g2
C1          C_11_g0  C_11_g1  C_11_g2
C2          C_12_g0  C_12_g1  C_12_g2
C3          C_13_g0  C_13_g1  C_13_g2
R0          R1
R_10_g0  R_11_g0    R0C0    R0C1    R0C2
R_10_g1  R_11_g1    R1C0    R1C1    R1C2
R_10_g2  R_11_g2    R2C0    R2C1    R2C2
R_10_g3  R_11_g3    R3C0    R3C1    R3C2
R_10_g4  R_11_g4    R4C0    R4C1    R4C2
```

`read_csv` is also able to interpret a more common format of multi-columns indices.

```
In [183]: print(open('mi2.csv').read())
,a,a,a,b,c,c
,q,r,s,t,u,v
```

(continues on next page)

(continued from previous page)

```
one,1,2,3,4,5,6
two,7,8,9,10,11,12

In [184]: pd.read_csv('mi2.csv', header=[0, 1], index_col=0)
Out[184]:
   a      b      c
   q    r    s    t    u    v
one  1    2    3    4    5    6
two  7    8    9   10   11   12
```

Note: If an `index_col` is not specified (e.g. you don't have an index, or wrote it with `df.to_csv(..., index=False)`), then any names on the columns index will be *lost*.

Automatically “sniffing” the delimiter

`read_csv` is capable of inferring delimited (not necessarily comma-separated) files, as pandas uses the `CSV.Sniffer` class of the `csv` module. For this, you have to specify `sep=None`.

```
In [185]: print(open('tmp2.sv').read())
:0:1:2:3

```

Reading multiple files to create a single DataFrame

It's best to use `concat()` to combine multiple files. See the [cookbook](#) for an example.

Iterating through files chunk by chunk

Suppose you wish to iterate through a (potentially very large) file lazily rather than reading the entire file into memory, such as the following:

```
In [187]: print(open('tmp.csv').read())
|0|1|2|3
0|1.1214905765122583|-1.1011663421613171|-1.2725711408453018|0.8434589457722285
1|0.8739661419816901|-1.1622548707272122|0.12618578996106738|0.5057848504967111
2|0.6695152369722812|0.4833977900441433|-0.4383565886430891|-0.13952146077085656
3|1.6678766138462109|0.906356209978661|0.8603041052486606|-0.009413710135323125
4|-0.8075485015292924|-0.7848128653629299|-1.3155155066668116|0.6875244729698119
5|-0.1572352664979729|0.30339976035788174|-0.36340691002502046|-0.5526511482544121
6|0.41442095212262187|0.17517103850750262|-0.5295157789486404|-0.06745694327155764
7|1.058814717443789|-0.11789792502832808|-1.8534207864364352|-0.7018494437516053

9|0.6352851164219758|-2.1785482358583024|0.3120437647651685|1.5723784501068536

In [188]: table = pd.read_csv('tmp.csv', sep='|')

In [189]: table
Out[189]:
   Unnamed: 0      0      1      2      3
0      0  1.121491 -1.101166 -1.272571  0.843459
1      1  0.873966 -1.162255  0.126186  0.505785
2      2  0.669515  0.483398 -0.438357 -0.139521
3      3  1.667877  0.906356  0.860304 -0.009414
4      4 -0.807549 -0.784813 -1.315516  0.687524
5      5 -0.157235  0.303400 -0.363407 -0.552651
6      6  0.414421  0.175171 -0.529516 -0.067457
7      7  1.058815 -0.117898 -1.853421 -0.701849
8      8  0.262396 -1.724596  0.276580  1.073024
9      9  0.635285 -2.178548  0.312044  1.572378
```

By specifying a `chunksize` to `read_csv`, the return value will be an iterable object of type `TextFileReader`:

```
In [190]: reader = pd.read_csv('tmp.csv', sep='|', chunksize=4)

In [191]: reader
Out[191]: <pandas.io.parsers.TextFileReader at 0x7f6d704e6f10>

In [192]: for chunk in reader:
.....:     print(chunk)
.....:
   Unnamed: 0      0      1      2      3
0      0  1.121491 -1.101166 -1.272571  0.843459
1      1  0.873966 -1.162255  0.126186  0.505785
2      2  0.669515  0.483398 -0.438357 -0.139521
3      3  1.667877  0.906356  0.860304 -0.009414
   Unnamed: 0      0      1      2      3
4      4 -0.807549 -0.784813 -1.315516  0.687524
5      5 -0.157235  0.303400 -0.363407 -0.552651
```

(continues on next page)

(continued from previous page)

6	6	0.414421	0.175171	-0.529516	-0.067457
7	7	1.058815	-0.117898	-1.853421	-0.701849
	Unnamed: 0	0	1	2	3
8	8	0.262396	-1.724596	0.276580	1.073024
9	9	0.635285	-2.178548	0.312044	1.572378

Specifying `iterator=True` will also return the `TextFileReader` object:

```
In [193]: reader = pd.read_csv('tmp.csv', sep='|', iterator=True)
```

```
In [194]: reader.get_chunk(5)
```

```
Out[194]:
```

	Unnamed: 0	0	1	2	3
0	0	1.121491	-1.101166	-1.272571	0.843459
1	1	0.873966	-1.162255	0.126186	0.505785
2	2	0.669515	0.483398	-0.438357	-0.139521
3	3	1.667877	0.906356	0.860304	-0.009414

Specifying the parser engine

Under the hood pandas uses a fast and efficient parser implemented in C as well as a Python implementation which is currently more feature-complete. Where possible pandas uses the C parser (specified as `engine='c'`), but may fall back to Python if C-unsupported options are specified. Currently, C-unsupported options include:

- `sep` other than a single character (e.g. regex separators)
- `skipfooter`
- `sep=None` with `delim_whitespace=False`

Specifying any of the above options will produce a `ParserWarning` unless the python engine is selected explicitly using `engine='python'`.

Reading remote files

You can pass in a URL to a CSV file:

```
df = pd.read_csv('https://download.bls.gov/pub/time.series/cu/cu.item',
                 sep='\t')
```

S3 URLs are handled as well but require installing the `S3Fs` library:

```
df = pd.read_csv('s3://pandas-test/tips.csv')
```

If your S3 bucket requires credentials you will need to set them as environment variables or in the `~/.aws/credentials` config file, refer to the `S3Fs` documentation on credentials.

Writing out data

Writing to CSV format

The `Series` and `DataFrame` objects have an instance method `to_csv` which allows storing the contents of the object as a comma-separated-values file. The function takes a number of arguments. Only the first is required.

- `path_or_buf`: A string path to the file to write or a file object. If a file object it must be opened with `newline=`
- `sep` : Field delimiter for the output file (default “,”)
- `na_rep`: A string representation of a missing value (default ‘’)
- `float_format`: Format string for floating point numbers
- `columns`: Columns to write (default None)
- `header`: Whether to write out the column names (default True)
- `index`: whether to write row (index) names (default True)
- `index_label`: Column label(s) for index column(s) if desired. If None (default), and `header` and `index` are True, then the index names are used. (A sequence should be given if the `DataFrame` uses MultiIndex).
- `mode` : Python write mode, default ‘w’
- `encoding`: a string representing the encoding to use if the contents are non-ASCII, for Python versions prior to 3
- `line_terminator`: Character sequence denoting line end (default `os.linesep`)
- `quoting`: Set quoting rules as in csv module (default `csv.QUOTE_MINIMAL`). Note that if you have set a `float_format` then floats are converted to strings and `csv.QUOTE_NONNUMERIC` will treat them as non-numeric
- `quotechar`: Character used to quote fields (default “””)
- `doublequote`: Control quoting of `quotechar` in fields (default True)
- `escapechar`: Character used to escape `sep` and `quotechar` when appropriate (default None)
- `chunksize`: Number of rows to write at a time
- `date_format`: Format string for datetime objects

Writing a formatted string

The `DataFrame` object has an instance method `to_string` which allows control over the string representation of the object. All arguments are optional:

- `buf` default None, for example a `StringIO` object
- `columns` default None, which columns to write
- `col_space` default None, minimum width of each column.
- `na_rep` default `NaN`, representation of NA value
- `formatters` default None, a dictionary (by column) of functions each of which takes a single argument and returns a formatted string
- `float_format` default None, a function which takes a single (float) argument and returns a formatted string; to be applied to floats in the `DataFrame`.

- `sparsify` default True, set to False for a DataFrame with a hierarchical index to print every MultiIndex key at each row.
- `index_names` default True, will print the names of the indices
- `index` default True, will print the index (ie, row labels)
- `header` default True, will print the column labels
- `justify` default left, will print column headers left- or right-justified

The Series object also has a `to_string` method, but with only the `buf`, `na_rep`, `float_format` arguments. There is also a `length` argument which, if set to True, will additionally output the length of the Series.

3.1.2 JSON

Read and write JSON format files and strings.

Writing JSON

A Series or DataFrame can be converted to a valid JSON string. Use `to_json` with optional parameters:

- `path_or_buf` : the pathname or buffer to write the output This can be None in which case a JSON string is returned
- `orient`:

Series:

- default is `index`
- allowed values are {`split`, `records`, `index`}

DataFrame:

- default is `columns`
- allowed values are {`split`, `records`, `index`, `columns`, `values`, `table`}

The format of the JSON string

<code>split</code>	dict like { <code>index</code> -> [<code>index</code>], <code>columns</code> -> [<code>columns</code>], <code>data</code> -> [<code>values</code>]}
<code>records</code>	list like [{ <code>column</code> -> <code>value</code> }, ..., { <code>column</code> -> <code>value</code> }]
<code>index</code>	dict like { <code>index</code> -> { <code>column</code> -> <code>value</code> }}
<code>columns</code>	dict like { <code>column</code> -> { <code>index</code> -> <code>value</code> }}
<code>values</code>	just the <code>values</code> array

- `date_format` : string, type of date conversion, ‘epoch’ for timestamp, ‘iso’ for ISO8601.
- `double_precision` : The number of decimal places to use when encoding floating point values, default 10.
- `force_ascii` : force encoded string to be ASCII, default True.
- `date_unit` : The time unit to encode to, governs timestamp and ISO8601 precision. One of ‘s’, ‘ms’, ‘us’ or ‘ns’ for seconds, milliseconds, microseconds and nanoseconds respectively. Default ‘ms’.
- `default_handler` : The handler to call if an object cannot otherwise be converted to a suitable format for JSON. Takes a single argument, which is the object to convert, and returns a serializable object.
- `lines` : If `records` orient, then will write each record per line as json.

Note NaN's, NaT's and None will be converted to null and datetime objects will be converted based on the date_format and date_unit parameters.

```
In [195]: dfj = pd.DataFrame(np.random.randn(5, 2), columns=list('AB'))  
  
In [196]: json = dfj.to_json()  
  
In [197]: json  
Out[197]: '{"A": {"0": 2.0027932898, "1": -1.1284197337, "2": -0.2671230751, "3": 0.  
    ↪ 0590811856, "4": 0.2126018166}, "B": {"0": 0.009310115, "1": -1.2591311739, "2": 1.  
    ↪ 7549089729, "3": 0.9464922966, "4": -0.5276761509}}'
```

Orient options

There are a number of different options for the format of the resulting JSON file / string. Consider the following DataFrame and Series:

```
In [198]: dfjo = pd.DataFrame(dict(A=range(1, 4), B=range(4, 7), C=range(7, 10)),  
    .....:  
    .....:  
  
In [199]: dfjo  
Out[199]:  
      A   B   C  
x   1   4   7  
y   2   5   8  
z   3   6   9  
  
In [200]: sjo = pd.Series(dict(x=15, y=16, z=17), name='D')  
  
In [201]: sjo  
Out[201]:  
x    15  
y    16  
z    17  
Name: D, dtype: int64
```

Column oriented (the default for DataFrame) serializes the data as nested JSON objects with column labels acting as the primary index:

```
In [202]: dfjo.to_json(orient="columns")  
Out[202]: '{"A": {"x": 1, "y": 2, "z": 3}, "B": {"x": 4, "y": 5, "z": 6}, "C": {"x": 7, "y": 8, "z": 9}}'  
  
# Not available for Series
```

Index oriented (the default for Series) similar to column oriented but the index labels are now primary:

```
In [203]: dfjo.to_json(orient="index")  
Out[203]: {'x': {"A": 1, "B": 4, "C": 7}, "y": {"A": 2, "B": 5, "C": 8}, "z": {"A": 3, "B": 6, "C": 9}}  
  
In [204]: sjo.to_json(orient="index")  
Out[204]: {'x': 15, 'y': 16, 'z': 17}'
```

Record oriented serializes the data to a JSON array of column -> value records, index labels are not included. This is useful for passing DataFrame data to plotting libraries, for example the JavaScript library d3.js:

```
In [205]: dfjo.to_json(orient="records")
Out[205]: '[{"A":1,"B":4,"C":7}, {"A":2,"B":5,"C":8}, {"A":3,"B":6,"C":9}]'

In [206]: sjo.to_json(orient="records")
Out[206]: '[15,16,17]'
```

Value oriented is a bare-bones option which serializes to nested JSON arrays of values only, column and index labels are not included:

```
In [207]: dfjo.to_json(orient="values")
Out[207]: '[[1,4,7], [2,5,8], [3,6,9]]'

# Not available for Series
```

Split oriented serializes to a JSON object containing separate entries for values, index and columns. Name is also included for Series:

```
In [208]: dfjo.to_json(orient="split")
Out[208]: {'columns': ["A", "B", "C"], "index": ["x", "y", "z"], "data": [[1, 4, 7], [2, 5, 8], [3, 6, 9]]}

In [209]: sjo.to_json(orient="split")
Out[209]: {'name': "D", "index": ["x", "y", "z"], "data": [15, 16, 17]}
```

Table oriented serializes to the JSON Table Schema, allowing for the preservation of metadata including but not limited to dtypes and index names.

Note: Any orient option that encodes to a JSON object will not preserve the ordering of index and column labels during round-trip serialization. If you wish to preserve label ordering use the *split* option as it uses ordered containers.

Date handling

Writing in ISO date format:

```
In [210]: dfd = pd.DataFrame(np.random.randn(5, 2), columns=list('AB'))

In [211]: dfd['date'] = pd.Timestamp('20130101')

In [212]: dfd = dfd.sort_index(1, ascending=False)

In [213]: json = dfd.to_json(date_format='iso')

In [214]: json
Out[214]: {"date": {"0": "2013-01-01T00:00:00.000Z", "1": "2013-01-01T00:00:00.000Z", "2": "2013-01-01T00:00:00.000Z", "3": "2013-01-01T00:00:00.000Z", "4": "2013-01-01T00:00:00.000Z"}, "B": {"0": 0.3903383957, "1": -0.5223681486, "2": 2.0249145293, "3": 2.1144885256, "4": 0.5337588359}, "A": {"0": -1.0954121534, "1": -0.147141856, "2": 0.6305826658, "3": 1.5730764249, "4": 0.6200376615}}
```

Writing in ISO date format, with microseconds:

```
In [215]: json = dfd.to_json(date_format='iso', date_unit='us')
```

(continues on next page)

(continued from previous page)

```
In [216]: json
Out[216]: '{"date": {"0": "2013-01-01T00:00:00.000000Z", "1": "2013-01-01T00:00:00.000000Z", "2": "2013-01-01T00:00:00.000000Z", "3": "2013-01-01T00:00:00.000000Z", "4": "2013-01-01T00:00:00.000000Z"}, "B": {"0": 0.3903383957, "1": -0.5223681486, "2": 2.0249145293, "3": 2.1144885256, "4": 0.5337588359}, "A": {"0": -1.0954121534, "1": -0.147141856, "2": 0.6305826658, "3": 1.5730764249, "4": 0.6200376615}}'
```

Epoch timestamps, in seconds:

```
In [217]: json = dfd.to_json(date_format='epoch', date_unit='s')

In [218]: json
Out[218]: '{"date": {"0": 1356998400, "1": 1356998400, "2": 1356998400, "3": 1356998400, "4": 1356998400}, "B": {"0": 0.3903383957, "1": -0.5223681486, "2": 2.0249145293, "3": 2.1144885256, "4": 0.5337588359}, "A": {"0": -1.0954121534, "1": -0.147141856, "2": 0.6305826658, "3": 1.5730764249, "4": 0.6200376615}}'
```

Writing to a file, with a date index and a date column:

```
In [219]: dfj2 = dfj.copy()

In [220]: dfj2['date'] = pd.Timestamp('20130101')

In [221]: dfj2['ints'] = list(range(5))

In [222]: dfj2['bools'] = True

In [223]: dfj2.index = pd.date_range('20130101', periods=5)

In [224]: dfj2.to_json('test.json')

In [225]: with open('test.json') as fh:
.....:     print(fh.read())
.....:
{"A": {"1356998400000": 2.0027932898, "1357084800000": -1.1284197337, "1357171200000": -0.2671230751, "1357257600000": 0.0590811856, "1357344000000": 0.2126018166}, "B": {"1356998400000": 0.009310115, "1357084800000": -1.2591311739, "1357171200000": 1.7549089729, "1357257600000": 0.9464922966, "1357344000000": -0.5276761509}, "date": {"1356998400000": 1356998400000, "1357084800000": 1356998400000, "1357171200000": 1356998400000, "1357257600000": 1356998400000, "1357344000000": 1356998400000}, "ints": {"1356998400000": 0, "1357084800000": 1, "1357171200000": 2, "1357257600000": 3, "1357344000000": 4}, "bools": {"1356998400000": true, "1357084800000": true, "1357171200000": true, "1357257600000": true, "1357344000000": true}}
```

Fallback behavior

If the JSON serializer cannot handle the container contents directly it will fall back in the following manner:

- if the dtype is unsupported (e.g. np.complex) then the `default_handler`, if provided, will be called for each value, otherwise an exception is raised.
- if an object is unsupported it will attempt the following:
 - check if the object has defined a `toDict` method and call it. A `toDict` method should return a dict which will then be JSON serialized.
 - invoke the `default_handler` if one was provided.

- convert the object to a dict by traversing its contents. However this will often fail with an `OverflowError` or give unexpected results.

In general the best approach for unsupported objects or dtypes is to provide a `default_handler`. For example:

```
>>> DataFrame([1.0, 2.0, complex(1.0, 2.0)]).to_json()    # raises
RuntimeError: Unhandled numpy dtype 15
```

can be dealt with by specifying a simple `default_handler`:

```
In [226]: pd.DataFrame([1.0, 2.0, complex(1.0, 2.0)]).to_json(default_handler=str)
Out[226]: '{"0":{"0":"(1+0j)", "1":"(2+0j)", "2":"(1+2j)"}}'
```

Reading JSON

Reading a JSON string to pandas object can take a number of parameters. The parser will try to parse a `DataFrame` if `typ` is not supplied or is `None`. To explicitly force `Series` parsing, pass `typ=series`

- `filepath_or_buffer` : a **VALID** JSON string or file handle / `StringIO`. The string could be a URL. Valid URL schemes include `http`, `ftp`, `S3`, and `file`. For file URLs, a host is expected. For instance, a local file could be file `://localhost/path/to/table.json`
- `typ` : type of object to recover (series or frame), default ‘frame’
- `orient` :

`Series` :

- default is `index`
- allowed values are {`split`, `records`, `index`}

`DataFrame`

- default is `columns`
- allowed values are {`split`, `records`, `index`, `columns`, `values`, `table`}

The format of the JSON string

<code>split</code>	dict like { <code>index</code> -> [<code>index</code>], <code>columns</code> -> [<code>columns</code>], <code>data</code> -> [<code>values</code>]}
<code>records</code>	list like [{ <code>column</code> -> <code>value</code> }, ..., { <code>column</code> -> <code>value</code> }]
<code>index</code>	dict like { <code>index</code> -> { <code>column</code> -> <code>value</code> }}
<code>columns</code>	dict like { <code>column</code> -> { <code>index</code> -> <code>value</code> }}
<code>values</code>	just the values array
<code>table</code>	adhering to the JSON <code>Table Schema</code>

- `dtype` : if `True`, infer dtypes, if a dict of column to `dtype`, then use those, if `False`, then don’t infer dtypes at all, `default` is `True`, apply only to the data.
- `convert_axes` : boolean, try to convert the axes to the proper dtypes, `default` is `True`
- `convert_dates` : a list of columns to parse for dates; If `True`, then try to parse date-like columns, `default` is `True`.
- `keep_default_dates` : boolean, `default True`. If parsing dates, then parse the default date-like columns.
- `numpy` : direct decoding to NumPy arrays. `default` is `False`; Supports numeric data only, although labels may be non-numeric. Also note that the JSON ordering **MUST** be the same for each term if `numpy=True`.

- `precise_float` : boolean, default `False`. Set to enable usage of higher precision (`strtod`) function when decoding string to double values. Default (`False`) is to use fast but less precise builtin functionality.
- `date_unit` : string, the timestamp unit to detect if converting dates. Default `None`. By default the timestamp precision will be detected, if this is not desired then pass one of `'s'`, `'ms'`, `'us'` or `'ns'` to force timestamp precision to seconds, milliseconds, microseconds or nanoseconds respectively.
- `lines` : reads file as one json object per line.
- `encoding` : The encoding to use to decode py3 bytes.
- `chunksize` : when used in combination with `lines=True`, return a `JsonReader` which reads in `chunksize` lines per iteration.

The parser will raise one of `ValueError`/`TypeError`/`AssertionError` if the JSON is not parseable.

If a non-default `orient` was used when encoding to JSON be sure to pass the same option here so that decoding produces sensible results, see [Orient Options](#) for an overview.

Data conversion

The default of `convert_axes=True`, `dtype=True`, and `convert_dates=True` will try to parse the axes, and all of the data into appropriate types, including dates. If you need to override specific dtypes, pass a dict to `dtype`. `convert_axes` should only be set to `False` if you need to preserve string-like numbers (e.g. `'1'`, `'2'`) in an axes.

Note: Large integer values may be converted to dates if `convert_dates=True` and the data and / or column labels appear ‘date-like’. The exact threshold depends on the `date_unit` specified. ‘date-like’ means that the column label meets one of the following criteria:

- it ends with `'_at'`
 - it ends with `'_time'`
 - it begins with `'timestamp'`
 - it is `'modified'`
 - it is `'date'`
-

Warning: When reading JSON data, automatic coercing into dtypes has some quirks:

- an index can be reconstructed in a different order from serialization, that is, the returned order is not guaranteed to be the same as before serialization
- a column that was `float` data will be converted to `integer` if it can be done safely, e.g. a column of `1`.
- `bool` columns will be converted to `integer` on reconstruction

Thus there are times where you may want to specify specific dtypes via the `dtype` keyword argument.

Reading from a JSON string:

```
In [227]: pd.read_json(json)
Out[227]:
```

	date	B	A
0	2013-01-01	0.390338	-1.095412
1	2013-01-01	-0.522368	-0.147142

(continues on next page)

(continued from previous page)

2	2013-01-01	2.024915	0.630583
3	2013-01-01	2.114489	1.573076
4	2013-01-01	0.533759	0.620038

Reading from a file:

```
In [228]: pd.read_json('test.json')
Out[228]:
      A          B      date  ints  bools
2013-01-01  2.002793  0.009310 2013-01-01      0   True
2013-01-02 -1.128420 -1.259131 2013-01-01      1   True
2013-01-03 -0.267123  1.754909 2013-01-01      2   True
2013-01-04  0.059081  0.946492 2013-01-01      3   True
2013-01-05  0.212602 -0.527676 2013-01-01      4   True
```

Don't convert any data (but still convert axes and dates):

```
In [229]: pd.read_json('test.json', dtype=object).dtypes
Out[229]:
A        object
B        object
date    object
ints    object
bools   object
dtype: object
```

Specify dtypes for conversion:

```
In [230]: pd.read_json('test.json', dtype={'A': 'float32', 'bools': 'int8'}).dtypes
Out[230]:
A            float32
B            float64
date      datetime64[ns]
ints         int64
bools          int8
dtype: object
```

Preserve string indices:

```
In [231]: si = pd.DataFrame(np.zeros((4, 4)), columns=list(range(4)),
.....:                         index=[str(i) for i in range(4)])
.....:

In [232]: si
Out[232]:
      0    1    2    3
0  0.0  0.0  0.0  0.0
1  0.0  0.0  0.0  0.0
2  0.0  0.0  0.0  0.0
3  0.0  0.0  0.0  0.0

In [233]: si.index
Out[233]: Index(['0', '1', '2', '3'], dtype='object')

In [234]: si.columns
Out[234]: Int64Index([0, 1, 2, 3], dtype='int64')
```

(continues on next page)

(continued from previous page)

```
In [235]: json = si.to_json()

In [236]: sij = pd.read_json(json, convert_axes=False)

In [237]: sij
Out[237]:
   0   1   2   3
0   0   0   0   0
1   0   0   0   0
2   0   0   0   0
3   0   0   0   0

In [238]: sij.index
Out[238]: Index(['0', '1', '2', '3'], dtype='object')

In [239]: sij.columns
Out[239]: Index(['0', '1', '2', '3'], dtype='object')
```

Dates written in nanoseconds need to be read back in nanoseconds:

```
In [240]: json = dfj2.to_json(date_unit='ns')

# Try to parse timestamps as milliseconds -> Won't Work
In [241]: dfju = pd.read_json(json, date_unit='ms')

In [242]: dfju
Out[242]:

The Numpy parameter

Note: This param has been deprecated as of version 1.0.0 and will raise a `FutureWarning`.

This supports numeric data only. Index and columns labels may be non-numeric, e.g. strings, dates etc.

If `numpy=True` is passed to `read_json` an attempt will be made to sniff an appropriate `dtype` during deserialization and to subsequently decode directly to NumPy arrays, bypassing the need for intermediate Python objects.

This can provide speedups if you are deserialising a large amount of numeric data:

```
In [247]: randfloats = np.random.uniform(-100, 1000, 10000)

In [248]: randfloats.shape = (1000, 10)

In [249]: dffloats = pd.DataFrame(randfloats, columns=list('ABCDEFGHIJ'))

In [250]: jsonfloats = dffloats.to_json()
```

```
In [251]: %timeit pd.read_json(jsonfloats)
14 ms +- 569 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

```
In [252]: %timeit pd.read_json(jsonfloats, numpy=True)
11.4 ms +- 740 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

The speedup is less noticeable for smaller datasets:

```
In [253]: jsonfloats = dffloats.head(100).to_json()
```

```
In [254]: %timeit pd.read_json(jsonfloats)
8.26 ms +- 396 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

```
In [255]: %timeit pd.read_json(jsonfloats, numpy=True)
7.28 ms +- 432 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

Warning: Direct NumPy decoding makes a number of assumptions and may fail or produce unexpected output if these assumptions are not satisfied:

- data is numeric.
- data is uniform. The `dtype` is sniffed from the first value decoded. A `ValueError` may be raised, or incorrect output may be produced if this condition is not satisfied.
- labels are ordered. Labels are only read from the first container, it is assumed that each subsequent row / column has been encoded in the same order. This should be satisfied if the data was encoded using `to_json` but may not be the case if the JSON is from another source.

Normalization

pandas provides a utility function to take a dict or list of dicts and *normalize* this semi-structured data into a flat table.

```
In [256]: data = [{"id": 1, "name": {"first": "Coleen", "last": "Volk"}},
.....:             {"name": {"given": "Mose", "family": "Regner"}},
.....:             {"id": 2, "name": "Faye Raker"}]
```

```
In [257]: pd.json_normalize(data)
```

```
Out[257]:
```

	id	name.first	name.last	name.given	name.family	name
0	1.0	Coleen	Volk	NaN	NaN	NaN
1	NaN	NaN	NaN	Mose	Regner	NaN
2	2.0	NaN	NaN	NaN	NaN	Faye Raker

```
In [258]: data = [{"state": "Florida",
.....:                 "shortname": "FL",
.....:                 "info": {"governor": "Rick Scott"},
.....:                 "county": [{"name": "Dade", "population": 12345},
.....:                           {"name": "Broward", "population": 40000},
.....:                           {"name": "Palm Beach", "population": 60000}],
.....:                 {"state": "Ohio",
.....:                  "shortname": "OH",
.....:                  "info": {"governor": "John Kasich"},
.....:                  "county": [{"name": "Summit", "population": 1234},
.....:                            {"name": "Cuyahoga", "population": 1337}]}]
```

```
In [259]: pd.json_normalize(data, 'county', ['state', 'shortname', ['info', 'governor']])
```

```
Out[259]:
```

	name	population	state	shortname	info.governor
0	Dade	12345	Florida	FL	Rick Scott
1	Broward	40000	Florida	FL	Rick Scott
2	Palm Beach	60000	Florida	FL	Rick Scott
3	Summit	1234	Ohio	OH	John Kasich
4	Cuyahoga	1337	Ohio	OH	John Kasich

The max_level parameter provides more control over which level to end normalization. With max_level=1 the following snippet normalizes until 1st nesting level of the provided dict.

```
In [260]: data = [{"CreatedBy": {"Name": "User001"},
.....:                 "Lookup": {"TextField": "Some text",
.....:                           "UserField": {"Id": "ID001",
.....:                                         "Name": "Name001"}},
.....:                 "Image": {"a": "b"}}
.....:             }]
```

```
In [261]: pd.json_normalize(data, max_level=1)
```

```
Out[261]:
```

	CreatedBy.Name	Lookup.TextField	Lookup.UserField.Id	Lookup.UserField.Name	Image.a
0	User001	Some text	ID001	Name001	b

Line delimited json

pandas is able to read and write line-delimited json files that are common in data processing pipelines using Hadoop or Spark.

New in version 0.21.0.

For line-delimited json files, pandas can also return an iterator which reads in `chunksize` lines at a time. This can be useful for large files or to read from a stream.

```
In [262]: jsonl = '''
.....:     {"a": 1, "b": 2}
.....:     {"a": 3, "b": 4}
.....: '''
.....:

In [263]: df = pd.read_json(jsonl, lines=True)

In [264]: df
Out[264]:
   a   b
0  1   2
1  3   4

In [265]: df.to_json(orient='records', lines=True)
Out[265]: '{"a":1,"b":2}\n{"a":3,"b":4}'

# reader is an iterator that returns `chunksize` lines each iteration
In [266]: reader = pd.read_json(StringIO(jsonl), lines=True, chunksize=1)

In [267]: reader
Out[267]: <pandas.io.json.JsonReader at 0x7f6da59f3a10>

In [268]: for chunk in reader:
.....:     print(chunk)
.....:
Empty DataFrame
Columns: []
Index: []
   a   b
0  1   2
   a   b
1  3   4
```

Table schema

Table Schema is a spec for describing tabular datasets as a JSON object. The JSON includes information on the field names, types, and other attributes. You can use the `orient=table` to build a JSON string with two fields, `schema` and `data`.

```
In [269]: df = pd.DataFrame({'A': [1, 2, 3],
.....:                     'B': ['a', 'b', 'c'],
.....:                     'C': pd.date_range('2016-01-01', freq='d', periods=3)},
.....:                     index=pd.Index(range(3), name='idx'))
.....:

In [270]: df
```

(continues on next page)

(continued from previous page)

Out[270]:

	A	B	C
idx			
0	1	a	2016-01-01
1	2	b	2016-01-02
2	3	c	2016-01-03

In [271]: df.to_json(orient='table', date_format="iso")

```
Out[271]: {"schema": {"fields": [{"name": "idx", "type": "integer"}, {"name": "A", "type": "integer"}, {"name": "B", "type": "string"}, {"name": "C", "type": "datetime"}], "primaryKey": ["idx"], "pandas_version": "0.20.0"}, "data": [{"idx": 0, "A": 1, "B": "a", "C": "2016-01-01T00:00:00.000Z"}, {"idx": 1, "A": 2, "B": "b", "C": "2016-01-02T00:00:00.000Z"}, {"idx": 2, "A": 3, "B": "c", "C": "2016-01-03T00:00:00.000Z"}]}
```

The schema field contains the fields key, which itself contains a list of column name to type pairs, including the Index or MultiIndex (see below for a list of types). The schema field also contains a primaryKey field if the (Multi)index is unique.

The second field, data, contains the serialized data with the records orient. The index is included, and any datetimes are ISO 8601 formatted, as required by the Table Schema spec.

The full list of types supported are described in the Table Schema spec. This table shows the mapping from pandas types:

Pandas type	Table Schema type
int64	integer
float64	number
bool	boolean
datetime64[ns]	datetime
timedelta64[ns]	duration
categorical	any
object	str

A few notes on the generated table schema:

- The schema object contains a pandas_version field. This contains the version of pandas' dialect of the schema, and will be incremented with each revision.
- All dates are converted to UTC when serializing. Even timezone naive values, which are treated as UTC with an offset of 0.

In [272]: from pandas.io.json import build_table_schema**In [273]:** s = pd.Series(pd.date_range('2016', periods=4))**In [274]:** build_table_schema(s)**Out[274]:**

```
{"fields": [{"name": "index", "type": "integer"}, {"name": "values", "type": "datetime"}], "primaryKey": ["index"], "pandas_version": "0.20.0"}
```

- datetimes with a timezone (before serializing), include an additional field tz with the time zone name (e.g. 'US/Central').

```
In [275]: s_tz = pd.Series(pd.date_range('2016', periods=12,
.....:                                     tz='US/Central'))
.....:

In [276]: build_table_schema(s_tz)
Out[276]:
{'fields': [{name: 'index', type: 'integer'},
 {name: 'values', type: 'datetime', tz: 'US/Central'}],
'primaryKey': ['index'],
'pandas_version': '0.20.0'}
```

- Periods are converted to timestamps before serialization, and so have the same behavior of being converted to UTC. In addition, periods will contain an additional field freq with the period's frequency, e.g. 'A-DEC'.

```
In [277]: s_per = pd.Series(1, index=pd.period_range('2016', freq='A-DEC',
.....:                                         periods=4))
.....:

In [278]: build_table_schema(s_per)
Out[278]:
{'fields': [{name: 'index', type: 'datetime', freq: 'A-DEC'},
 {name: 'values', type: 'integer'}],
'primaryKey': ['index'],
'pandas_version': '0.20.0'}
```

- Categoricals use the any type and an enum constraint listing the set of possible values. Additionally, an ordered field is included:

```
In [279]: s_cat = pd.Series(pd.Categorical(['a', 'b', 'a']))

In [280]: build_table_schema(s_cat)
Out[280]:
{'fields': [{name: 'index', type: 'integer'},
 {name: 'values',
 'type': 'any',
 'constraints': {enum: ['a', 'b']},
 'ordered': False}],
'primaryKey': ['index'],
'pandas_version': '0.20.0'}
```

- A primaryKey field, containing an array of labels, is included *if the index is unique*:

```
In [281]: s_dupe = pd.Series([1, 2], index=[1, 1])

In [282]: build_table_schema(s_dupe)
Out[282]:
{'fields': [{name: 'index', type: 'integer'},
 {name: 'values', type: 'integer'}],
'pandas_version': '0.20.0'}
```

- The primaryKey behavior is the same with MultiIndexes, but in this case the primaryKey is an array:

```
In [283]: s_multi = pd.Series(1, index=pd.MultiIndex.from_product([('a', 'b'),
.....:                                         (0, 1)]))

In [284]: build_table_schema(s_multi)
```

(continues on next page)

(continued from previous page)

```
Out[284]: {'fields': [{name: 'level_0', type: 'string'}, {name: 'level_1', type: 'integer'}, {name: 'values', type: 'integer'}], primaryKey: FrozenList(['level_0', 'level_1']), pandas_version: '0.20.0'}
```

- The default naming roughly follows these rules:
 - For series, the object.name is used. If that's none, then the name is values
 - For DataFrames, the stringified version of the column name is used
 - For Index (not MultiIndex), index.name is used, with a fallback to index if that is None.
 - For MultiIndex, mi.names is used. If any level has no name, then level_<i> is used.

New in version 0.23.0.

read_json also accepts orient='table' as an argument. This allows for the preservation of metadata such as dtypes and index names in a round-trippable manner.

```
In [285]: df = pd.DataFrame({'foo': [1, 2, 3, 4],  
.....: 'bar': ['a', 'b', 'c', 'd'],  
.....: 'baz': pd.date_range('2018-01-01', freq='d', periods=4),  
.....: 'qux': pd.Categorical(['a', 'b', 'c', 'c'])  
.....: }, index=pd.Index(range(4), name='idx'))  
.....:  
  
In [286]: df  
Out[286]:  
      foo   bar       baz   qux  
idx  
0      1     a 2018-01-01     a  
1      2     b 2018-01-02     b  
2      3     c 2018-01-03     c  
3      4     d 2018-01-04     c  
  
In [287]: df.dtypes  
Out[287]:  
foo          int64  
bar         object  
baz    datetime64[ns]  
qux        category  
dtype: object  
  
In [288]: df.to_json('test.json', orient='table')  
  
In [289]: new_df = pd.read_json('test.json', orient='table')  
  
In [290]: new_df  
Out[290]:  
      foo   bar       baz   qux  
idx  
0      1     a 2018-01-01     a  
1      2     b 2018-01-02     b  
2      3     c 2018-01-03     c  
3      4     d 2018-01-04     c
```

(continues on next page)

(continued from previous page)

```
In [291]: new_df.dtypes
Out[291]:
foo           int64
bar          object
baz   datetime64[ns]
qux      category
dtype: object
```

Please note that the literal string ‘index’ as the name of an `Index` is not round-trippable, nor are any names beginning with `'level_'` within a `MultiIndex`. These are used by default in `DataFrame.to_json()` to indicate missing values and the subsequent read cannot distinguish the intent.

```
In [292]: df.index.name = 'index'

In [293]: df.to_json('test.json', orient='table')

In [294]: new_df = pd.read_json('test.json', orient='table')

In [295]: print(new_df.index.name)
None
```

3.1.3 HTML

Reading HTML content

Warning: We **highly encourage** you to read the [HTML Table Parsing gotchas](#) below regarding the issues surrounding the BeautifulSoup/html5lib/lxml parsers.

The top-level `read_html()` function can accept an HTML string/file/URL and will parse HTML tables into list of pandas DataFrames. Let’s look at a few examples.

Note: `read_html` returns a list of DataFrame objects, even if there is only a single table contained in the HTML content.

Read a URL with no options:

```
In [296]: url = 'https://www.fdic.gov/bank/individual/failed/banklist.html'

In [297]: dfs = pd.read_html(url)

In [298]: dfs
Out[298]:
[{'Acquiring Institution': 'Ericson State Bank', 'Bank Name': 'Ericson', 'City': 'Ericson', 'CERT': '18265', 'ST': 'NE', 'text_1': 'Farmers and', 'text_2': 'Merchants Bank', 'text_3': 'February 14, 2020', 'text_4': '1', 'text_5': 'City National Bank of New Jersey', 'text_6': 'Newark', 'text_7': '21111', 'text_8': 'Industrial Bank', 'text_9': 'November 1, 2019', 'text_10': 'Resolute Bank', 'text_11': 'Maumee', 'text_12': '58317', 'text_13': 'Buckeye State Bank', 'text_14': 'October 25, 2019'}]
```

[505 rows x 7 columns]]]
```

Note: The following examples are not run by the IPython evaluator due to the fact that having so many network-accessing functions slows down the documentation build. If you spot an error or an example that doesn't run, please do not hesitate to report it over on [pandas GitHub issues page](#).

Read a URL and match a table that contains specific text:

```
match = 'Metcalf Bank'
df_list = pd.read_html(url, match=match)
```

Specify a header row (by default `<th>` or `<td>` elements located within a `<thead>` are used to form the column index, if multiple rows are contained within `<thead>` then a MultiIndex is created); if specified, the header row is taken from the data minus the parsed header elements (`<th>` elements).

```
dfs = pd.read_html(url, header=0)
```

Specify an index column:

```
dfs = pd.read_html(url, index_col=0)
```

Specify a number of rows to skip:

```
dfs = pd.read_html(url, skiprows=0)
```

Specify a number of rows to skip using a list (xrange (Python 2 only) works as well):

```
dfs = pd.read_html(url, skiprows=range(2))
```

Specify an HTML attribute:

```
dfs1 = pd.read_html(url, attrs={'id': 'table'})  
dfs2 = pd.read_html(url, attrs={'class': 'sortable'})  
print(np.array_equal(dfs1[0], dfs2[0])) # Should be True
```

Specify values that should be converted to NaN:

```
dfs = pd.read_html(url, na_values=['No Acquirer'])
```

Specify whether to keep the default set of NaN values:

```
dfs = pd.read_html(url, keep_default_na=False)
```

Specify converters for columns. This is useful for numerical text data that has leading zeros. By default columns that are numerical are cast to numeric types and the leading zeros are lost. To avoid this, we can convert these columns to strings.

```
url_mcc = 'https://en.wikipedia.org/wiki/Mobile_country_code'  
dfs = pd.read_html(url_mcc, match='Telekom Albania', header=0,  
converters={'MNC': str})
```

Use some combination of the above:

```
dfs = pd.read_html(url, match='Metcalf Bank', index_col=0)
```

Read in pandas to_html output (with some loss of floating point precision):

```
df = pd.DataFrame(np.random.randn(2, 2))  
s = df.to_html(float_format='{0:.40g}'.format)  
dfin = pd.read_html(s, index_col=0)
```

The lxml backend will raise an error on a failed parse if that is the only parser you provide. If you only have a single parser you can provide just a string, but it is considered good practice to pass a list with one string if, for example, the function expects a sequence of strings. You may use:

```
dfs = pd.read_html(url, 'Metcalf Bank', index_col=0, flavor=['lxml'])
```

Or you could pass flavor='lxml' without a list:

```
dfs = pd.read_html(url, 'Metcalf Bank', index_col=0, flavor='lxml')
```

However, if you have bs4 and html5lib installed and pass None or ['lxml', 'bs4'] then the parse will most likely succeed. Note that *as soon as a parse succeeds, the function will return*.

```
dfs = pd.read_html(url, 'Metcalf Bank', index_col=0, flavor=['lxml', 'bs4'])
```

Writing to HTML files

DataFrame objects have an instance method `to_html` which renders the contents of the DataFrame as an HTML table. The function arguments are as in the method `to_string` described above.

Note: Not all of the possible options for `DataFrame.to_html` are shown here for brevity's sake. See `to_html()` for the full set of options.

```
In [304]: df = pd.DataFrame(np.random.randn(2, 2))

In [305]: df
Out[305]:
   0      1
0 -1.050304  1.131622
1 -0.692581 -1.174172

In [306]: print(df.to_html())  # raw html
<table border="1" class="dataframe">
  <thead>
    <tr style="text-align: right;">
      <th></th>
      <th>0</th>
      <th>1</th>
    </tr>
  </thead>
  <tbody>
    <tr>
      <th>0</th>
      <td>-1.050304</td>
      <td>1.131622</td>
    </tr>
    <tr>
      <th>1</th>
      <td>-0.692581</td>
      <td>-1.174172</td>
    </tr>
  </tbody>
</table>
```

HTML:

The `columns` argument will limit the columns shown:

```
In [307]: print(df.to_html(columns=[0]))
<table border="1" class="dataframe">
  <thead>
    <tr style="text-align: right;">
      <th></th>
      <th>0</th>
    </tr>
  </thead>
  <tbody>
    <tr>
      <th>0</th>
      <td>-1.050304</td>
    </tr>
  </tbody>
</table>
```

(continues on next page)

(continued from previous page)

```
<tr>
    <th>1</th>
    <td>-0.692581</td>
</tr>
</tbody>
</table>
```

HTML:

`float_format` takes a Python callable to control the precision of floating point values:

```
In [308]: print(df.to_html(float_format='{:,.10f}'.format))
<table border="1" class="dataframe">
    <thead>
        <tr style="text-align: right;">
            <th></th>
            <th>0</th>
            <th>1</th>
        </tr>
    </thead>
    <tbody>
        <tr>
            <th>0</th>
            <td>-1.0503044154</td>
            <td>1.1316218324</td>
        </tr>
        <tr>
            <th>1</th>
            <td>-0.6925807265</td>
            <td>-1.1741715747</td>
        </tr>
    </tbody>
</table>
```

HTML:

`bold_rows` will make the row labels bold by default, but you can turn that off:

```
In [309]: print(df.to_html(bold_rows=False))
<table border="1" class="dataframe">
    <thead>
        <tr style="text-align: right;">
            <th></th>
            <th>0</th>
            <th>1</th>
        </tr>
    </thead>
    <tbody>
        <tr>
            <td>0</td>
            <td>-1.050304</td>
            <td>1.131622</td>
        </tr>
        <tr>
            <td>1</td>
            <td>-0.692581</td>
            <td>-1.174172</td>
        </tr>
    </tbody>
</table>
```

(continues on next page)

(continued from previous page)

```
</tr>
</tbody>
</table>
```

The `classes` argument provides the ability to give the resulting HTML table CSS classes. Note that these classes are *appended* to the existing '`dataframe`' class.

```
In [310]: print(df.to_html(classes=['awesome_table_class', 'even_more_awesome_class
˓→']))
<table border="1" class="dataframe awesome_table_class even_more_awesome_class">
  <thead>
    <tr style="text-align: right;">
      <th></th>
      <th>0</th>
      <th>1</th>
    </tr>
  </thead>
  <tbody>
    <tr>
      <th>0</th>
      <td>-1.050304</td>
      <td>1.131622</td>
    </tr>
    <tr>
      <th>1</th>
      <td>-0.692581</td>
      <td>-1.174172</td>
    </tr>
  </tbody>
</table>
```

The `render_links` argument provides the ability to add hyperlinks to cells that contain URLs.

New in version 0.24.

```
In [311]: url_df = pd.DataFrame({
  ....:     'name': ['Python', 'Pandas'],
  ....:     'url': ['https://www.python.org/', 'https://pandas.pydata.org'])}
....:

In [312]: print(url_df.to_html(render_links=True))
<table border="1" class="dataframe">
  <thead>
    <tr style="text-align: right;">
      <th></th>
      <th>name</th>
      <th>url</th>
    </tr>
  </thead>
  <tbody>
    <tr>
      <th>0</th>
      <td>Python</td>
      <td><a href="https://www.python.org/" target="_blank">https://www.python.org/<
˓→a></td>
    </tr>
    <tr>
```

(continues on next page)

(continued from previous page)

```
<th>1</th>
<td>Pandas</td>
<td><a href="https://pandas.pydata.org" target="_blank">https://pandas.pydata.
↪org</a></td>
</tr>
</tbody>
</table>
```

HTML:

Finally, the `escape` argument allows you to control whether the “<”, “>” and “&” characters escaped in the resulting HTML (by default it is `True`). So to get the HTML without escaped characters pass `escape=False`

```
In [313]: df = pd.DataFrame({'a': list('&<>'), 'b': np.random.randn(3)})
```

Escaped:

```
In [314]: print(df.to_html())
<table border="1" class="dataframe">
<thead>
<tr style="text-align: right;">
<th></th>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<th>0</th>
<td>&amp;lt;</td>
<td>1.254800</td>
</tr>
<tr>
<th>1</th>
<td>&lt;</td>
<td>1.131996</td>
</tr>
<tr>
<th>2</th>
<td>&gt;</td>
<td>-1.311021</td>
</tr>
</tbody>
</table>
```

Not escaped:

```
In [315]: print(df.to_html(escape=False))
<table border="1" class="dataframe">
<thead>
<tr style="text-align: right;">
<th></th>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
```

(continues on next page)

(continued from previous page)

```

<tr>
    <th>0</th>
    <td>&</td>
    <td>1.254800</td>
</tr>
<tr>
    <th>1</th>
    <td><</td>
    <td>1.131996</td>
</tr>
<tr>
    <th>2</th>
    <td>></td>
    <td>-1.311021</td>
</tr>
</tbody>
</table>

```

Note: Some browsers may not show a difference in the rendering of the previous two HTML tables.

HTML Table Parsing Gotchas

There are some versioning issues surrounding the libraries that are used to parse HTML tables in the top-level pandas io function `read_html`.

Issues with `lxml`

- Benefits
 - `lxml` is very fast.
 - `lxml` requires Cython to install correctly.
- Drawbacks
 - `lxml` does *not* make any guarantees about the results of its parse *unless* it is given **strictly valid markup**.
 - In light of the above, we have chosen to allow you, the user, to use the `lxml` backend, but **this backend will use `html5lib` if `lxml` fails to parse**
 - It is therefore *highly recommended* that you install both `BeautifulSoup4` and `html5lib`, so that you will still get a valid result (provided everything else is valid) even if `lxml` fails.

Issues with `BeautifulSoup4` using `lxml` as a backend

- The above issues hold here as well since `BeautifulSoup4` is essentially just a wrapper around a parser backend.

Issues with `BeautifulSoup4` using `html5lib` as a backend

- Benefits
 - `html5lib` is far more lenient than `lxml` and consequently deals with *real-life markup* in a much saner way rather than just, e.g., dropping an element without notifying you.
 - `html5lib` generates valid HTML5 markup from invalid markup automatically. This is extremely important for parsing HTML tables, since it guarantees a valid document. However, that does NOT mean that it is “correct”, since the process of fixing markup does not have a single definition.
 - `html5lib` is pure Python and requires no additional build steps beyond its own installation.

- Drawbacks

- The biggest drawback to using `html5lib` is that it is slow as molasses. However consider the fact that many tables on the web are not big enough for the parsing algorithm runtime to matter. It is more likely that the bottleneck will be in the process of reading the raw text from the URL over the web, i.e., IO (input-output). For very large tables, this might not be true.

3.1.4 Excel files

The `read_excel()` method can read Excel 2003 (.xls) files using the `xlrd` Python module. Excel 2007+ (.xlsx) files can be read using either `xlrd` or `openpyxl`. Binary Excel (.xlsb) files can be read using `pyxlsb`. The `to_excel()` instance method is used for saving a DataFrame to Excel. Generally the semantics are similar to working with `csv` data. See the `cookbook` for some advanced strategies.

Reading Excel files

In the most basic use-case, `read_excel` takes a path to an Excel file, and the `sheet_name` indicating which sheet to parse.

```
# Returns a DataFrame
pd.read_excel('path_to_file.xls', sheet_name='Sheet1')
```

ExcelFile class

To facilitate working with multiple sheets from the same file, the `ExcelFile` class can be used to wrap the file and can be passed into `read_excel`. There will be a performance benefit for reading multiple sheets as the file is read into memory only once.

```
xlsx = pd.ExcelFile('path_to_file.xls')
df = pd.read_excel(xlsx, 'Sheet1')
```

The `ExcelFile` class can also be used as a context manager.

```
with pd.ExcelFile('path_to_file.xls') as xls:
    df1 = pd.read_excel(xls, 'Sheet1')
    df2 = pd.read_excel(xls, 'Sheet2')
```

The `sheet_names` property will generate a list of the sheet names in the file.

The primary use-case for an `ExcelFile` is parsing multiple sheets with different parameters:

```
data = {}
# For when Sheet1's format differs from Sheet2
with pd.ExcelFile('path_to_file.xls') as xls:
    data['Sheet1'] = pd.read_excel(xls, 'Sheet1', index_col=None,
                                   na_values=['NA'])
    data['Sheet2'] = pd.read_excel(xls, 'Sheet2', index_col=1)
```

Note that if the same parsing parameters are used for all sheets, a list of sheet names can simply be passed to `read_excel` with no loss in performance.

```
# using the ExcelFile class
data = {}
with pd.ExcelFile('path_to_file.xls') as xls:
    data['Sheet1'] = pd.read_excel(xls, 'Sheet1', index_col=None,
                                   na_values=['NA'])
    data['Sheet2'] = pd.read_excel(xls, 'Sheet2', index_col=None,
                                   na_values=['NA'])

# equivalent using the read_excel function
data = pd.read_excel('path_to_file.xls', ['Sheet1', 'Sheet2'],
                     index_col=None, na_values=['NA'])
```

`ExcelFile` can also be called with a `xlrd.book.Book` object as a parameter. This allows the user to control how the excel file is read. For example, sheets can be loaded on demand by calling `xlrd.open_workbook()` with `on_demand=True`.

```
import xlrd
xlrd_book = xlrd.open_workbook('path_to_file.xls', on_demand=True)
with pd.ExcelFile(xlrd_book) as xls:
    df1 = pd.read_excel(xls, 'Sheet1')
    df2 = pd.read_excel(xls, 'Sheet2')
```

Specifying sheets

Note: The second argument is `sheet_name`, not to be confused with `ExcelFile.sheet_names`.

Note: An `ExcelFile`'s attribute `sheet_names` provides access to a list of sheets.

- The arguments `sheet_name` allows specifying the sheet or sheets to read.
- The default value for `sheet_name` is 0, indicating to read the first sheet
- Pass a string to refer to the name of a particular sheet in the workbook.
- Pass an integer to refer to the index of a sheet. Indices follow Python convention, beginning at 0.
- Pass a list of either strings or integers, to return a dictionary of specified sheets.
- Pass a `None` to return a dictionary of all available sheets.

```
# Returns a DataFrame
pd.read_excel('path_to_file.xls', 'Sheet1', index_col=None, na_values=['NA'])
```

Using the sheet index:

```
# Returns a DataFrame
pd.read_excel('path_to_file.xls', 0, index_col=None, na_values=['NA'])
```

Using all default values:

```
# Returns a DataFrame
pd.read_excel('path_to_file.xls')
```

Using `None` to get all sheets:

```
# Returns a dictionary of DataFrames
pd.read_excel('path_to_file.xls', sheet_name=None)
```

Using a list to get multiple sheets:

```
# Returns the 1st and 4th sheet, as a dictionary of DataFrames.
pd.read_excel('path_to_file.xls', sheet_name=['Sheet1', 3])
```

`read_excel` can read more than one sheet, by setting `sheet_name` to either a list of sheet names, a list of sheet positions, or `None` to read all sheets. Sheets can be specified by sheet index or sheet name, using an integer or string, respectively.

Reading a MultiIndex

`read_excel` can read a `MultiIndex` index, by passing a list of columns to `index_col` and a `MultiIndex` column by passing a list of rows to `header`. If either the `index` or `columns` have serialized level names those will be read in as well by specifying the rows/columns that make up the levels.

For example, to read in a `MultiIndex` index without names:

```
In [316]: df = pd.DataFrame({'a': [1, 2, 3, 4], 'b': [5, 6, 7, 8]},
.....:                               index=pd.MultiIndex.from_product([['a', 'b'], ['c', 'd',
↔']])
.....:

In [317]: df.to_excel('path_to_file.xlsx')

In [318]: df = pd.read_excel('path_to_file.xlsx', index_col=[0, 1])

In [319]: df
Out[319]:
      a   b
a c  1  5
  d  2  6
b c  3  7
  d  4  8
```

If the index has level names, they will parsed as well, using the same parameters.

```
In [320]: df.index = df.index.set_names(['lvl1', 'lvl2'])

In [321]: df.to_excel('path_to_file.xlsx')

In [322]: df = pd.read_excel('path_to_file.xlsx', index_col=[0, 1])

In [323]: df
Out[323]:
      a   b
lvl1 lvl2
a     c  1  5
      d  2  6
b     c  3  7
      d  4  8
```

If the source file has both `MultiIndex` index and columns, lists specifying each should be passed to `index_col` and `header`:

```
In [324]: df.columns = pd.MultiIndex.from_product([[['a'], ['b', 'd']]],
.....:
.....:

In [325]: df.to_excel('path_to_file.xlsx')

In [326]: df = pd.read_excel('path_to_file.xlsx', index_col=[0, 1], header=[0, 1])

In [327]: df
Out[327]:
c1      a
c2      b  d
lvl1 lvl2
a    c    1  5
     d    2  6
b    c    3  7
     d    4  8
```

Parsing specific columns

It is often the case that users will insert columns to do temporary computations in Excel and you may not want to read in those columns. `read_excel` takes a `usecols` keyword to allow you to specify a subset of columns to parse.

Deprecated since version 0.24.0.

Passing in an integer for `usecols` has been deprecated. Please pass in a list of ints from 0 to `usecols` inclusive instead.

If `usecols` is an integer, then it is assumed to indicate the last column to be parsed.

```
pd.read_excel('path_to_file.xls', 'Sheet1', usecols=2)
```

You can also specify a comma-delimited set of Excel columns and ranges as a string:

```
pd.read_excel('path_to_file.xls', 'Sheet1', usecols='A,C:E')
```

If `usecols` is a list of integers, then it is assumed to be the file column indices to be parsed.

```
pd.read_excel('path_to_file.xls', 'Sheet1', usecols=[0, 2, 3])
```

Element order is ignored, so `usecols=[0, 1]` is the same as `[1, 0]`.

New in version 0.24.

If `usecols` is a list of strings, it is assumed that each string corresponds to a column name provided either by the user in `names` or inferred from the document header row(s). Those strings define which columns will be parsed:

```
pd.read_excel('path_to_file.xls', 'Sheet1', usecols=['foo', 'bar'])
```

Element order is ignored, so `usecols=['baz', 'joe']` is the same as `['joe', 'baz']`.

New in version 0.24.

If `usecols` is callable, the callable function will be evaluated against the column names, returning names where the callable function evaluates to `True`.

```
pd.read_excel('path_to_file.xls', 'Sheet1', usecols=lambda x: x.isalpha())
```

Parsing dates

Datetime-like values are normally automatically converted to the appropriate dtype when reading the excel file. But if you have a column of strings that *look* like dates (but are not actually formatted as dates in excel), you can use the `parse_dates` keyword to parse those strings to datetimes:

```
pd.read_excel('path_to_file.xls', 'Sheet1', parse_dates=['date_strings'])
```

Cell converters

It is possible to transform the contents of Excel cells via the `converters` option. For instance, to convert a column to boolean:

```
pd.read_excel('path_to_file.xls', 'Sheet1', converters={'MyBools': bool})
```

This options handles missing values and treats exceptions in the converters as missing data. Transformations are applied cell by cell rather than to the column as a whole, so the array dtype is not guaranteed. For instance, a column of integers with missing values cannot be transformed to an array with integer dtype, because NaN is strictly a float. You can manually mask missing data to recover integer dtype:

```
def cfun(x):
    return int(x) if x else -1
```

```
pd.read_excel('path_to_file.xls', 'Sheet1', converters={'MyInts': cfun})
```

Dtype specifications

As an alternative to converters, the type for an entire column can be specified using the `dtype` keyword, which takes a dictionary mapping column names to types. To interpret data with no type inference, use the type `str` or `object`.

```
pd.read_excel('path_to_file.xls', dtype={'MyInts': 'int64', 'MyText': str})
```

Writing Excel files

Writing Excel files to disk

To write a `DataFrame` object to a sheet of an Excel file, you can use the `to_excel` instance method. The arguments are largely the same as `to_csv` described above, the first argument being the name of the excel file, and the optional second argument the name of the sheet to which the `DataFrame` should be written. For example:

```
df.to_excel('path_to_file.xlsx', sheet_name='Sheet1')
```

Files with a `.xls` extension will be written using `xlwt` and those with a `.xlsx` extension will be written using `xlsxwriter` (if available) or `openpyxl`.

The `DataFrame` will be written in a way that tries to mimic the REPL output. The `index_label` will be placed in the second row instead of the first. You can place it in the first row by setting the `merge_cells` option in `to_excel()` to `False`:

```
df.to_excel('path_to_file.xlsx', index_label='label', merge_cells=False)
```

In order to write separate DataFrames to separate sheets in a single Excel file, one can pass an ExcelWriter.

```
with pd.ExcelWriter('path_to_file.xlsx') as writer:
    df1.to_excel(writer, sheet_name='Sheet1')
    df2.to_excel(writer, sheet_name='Sheet2')
```

Note: Wringing a little more performance out of `read_excel` Internally, Excel stores all numeric data as floats. Because this can produce unexpected behavior when reading in data, pandas defaults to trying to convert integers to floats if it doesn't lose information (`1.0 --> 1`). You can pass `convert_float=False` to disable this behavior, which may give a slight performance improvement.

Writing Excel files to memory

Pandas supports writing Excel files to buffer-like objects such as `StringIO` or `BytesIO` using `ExcelWriter`.

```
# Safe import for either Python 2.x or 3.x
try:
    from io import BytesIO
except ImportError:
    from cStringIO import StringIO as BytesIO

bio = BytesIO()

# By setting the 'engine' in the ExcelWriter constructor.
writer = pd.ExcelWriter(bio, engine='xlsxwriter')
df.to_excel(writer, sheet_name='Sheet1')

# Save the workbook
writer.save()

# Seek to the beginning and read to copy the workbook to a variable in memory
bio.seek(0)
workbook = bio.read()
```

Note: `engine` is optional but recommended. Setting the `engine` determines the version of workbook produced. Setting `engine='xlrd'` will produce an Excel 2003-format workbook (xls). Using either '`openpyxl`' or '`xlsxwriter`' will produce an Excel 2007-format workbook (xlsx). If omitted, an Excel 2007-formatted workbook is produced.

Excel writer engines

Pandas chooses an Excel writer via two methods:

1. the engine keyword argument
2. the filename extension (via the default specified in config options)

By default, pandas uses the `XlsxWriter` for `.xlsx`, `openpyxl` for `.xslm`, and `xlwt` for `.xls` files. If you have multiple engines installed, you can set the default engine through *setting the config options* `io.excel.xlsx.writer` and `io.excel.xls.writer`. pandas will fall back on `openpyxl` for `.xlsx` files if `Xlsxwriter` is not available.

To specify which writer you want to use, you can pass an engine keyword argument to `to_excel` and to `ExcelWriter`. The built-in engines are:

- `openpyxl`: version 2.4 or higher is required
- `xlsxwriter`
- `xlwt`

```
# By setting the 'engine' in the DataFrame 'to_excel()' methods.
df.to_excel('path_to_file.xlsx', sheet_name='Sheet1', engine='xlsxwriter')

# By setting the 'engine' in the ExcelWriter constructor.
writer = pd.ExcelWriter('path_to_file.xlsx', engine='xlsxwriter')

# Or via pandas configuration.
from pandas import options # noqa: E402
options.io.excel.xlsx.writer = 'xlsxwriter'

df.to_excel('path_to_file.xlsx', sheet_name='Sheet1')
```

Style and formatting

The look and feel of Excel worksheets created from pandas can be modified using the following parameters on the `DataFrame`'s `to_excel` method.

- `float_format` : Format string for floating point numbers (default `None`).
- `freeze_panes` : A tuple of two integers representing the bottommost row and rightmost column to freeze. Each of these parameters is one-based, so `(1, 1)` will freeze the first row and first column (default `None`).

Using the `Xlsxwriter` engine provides many options for controlling the format of an Excel worksheet created with the `to_excel` method. Excellent examples can be found in the `Xlsxwriter` documentation here: https://xlsxwriter.readthedocs.io/working_with_pandas.html

3.1.5 OpenDocument Spreadsheets

New in version 0.25.

The `read_excel()` method can also read OpenDocument spreadsheets using the `odfpy` module. The semantics and features for reading OpenDocument spreadsheets match what can be done for `Excel files` using `engine='odf'`.

```
# Returns a DataFrame
pd.read_excel('path_to_file.ods', engine='odf')
```

Note: Currently pandas only supports *reading* OpenDocument spreadsheets. Writing is not implemented.

3.1.6 Binary Excel (.xlsb) files

New in version 1.0.0.

The `read_excel()` method can also read binary Excel files using the `pyxlsb` module. The semantics and features for reading binary Excel files mostly match what can be done for *Excel files* using `engine='pyxlsb'`. `pyxlsb` does not recognize datetime types in files and will return floats instead.

```
# Returns a DataFrame
pd.read_excel('path_to_file.xlsb', engine='pyxlsb')
```

Note: Currently pandas only supports *reading* binary Excel files. Writing is not implemented.

3.1.7 Clipboard

A handy way to grab data is to use the `read_clipboard()` method, which takes the contents of the clipboard buffer and passes them to the `read_csv` method. For instance, you can copy the following text to the clipboard (CTRL-C on many operating systems):

```
A B C
x 1 4 p
y 2 5 q
z 3 6 r
```

And then import the data directly to a `DataFrame` by calling:

```
>>> clipdf = pd.read_clipboard()
>>> clipdf
   A B C
x 1 4 p
y 2 5 q
z 3 6 r
```

The `to_clipboard` method can be used to write the contents of a `DataFrame` to the clipboard. Following which you can paste the clipboard contents into other applications (CTRL-V on many operating systems). Here we illustrate writing a `DataFrame` into clipboard and reading it back.

```
>>> df = pd.DataFrame({'A': [1, 2, 3],
...                     'B': [4, 5, 6],
...                     'C': ['p', 'q', 'r']},
...                     index=['x', 'y', 'z'])
>>> df
   A B C
x 1 4 p
y 2 5 q
z 3 6 r
>>> df.to_clipboard()
>>> pd.read_clipboard()
   A B C
```

(continues on next page)

(continued from previous page)

```
x 1 4 p  
y 2 5 q  
z 3 6 r
```

We can see that we got the same content back, which we had earlier written to the clipboard.

Note: You may need to install xclip or xsel (with PyQt5, PyQt4 or qtpy) on Linux to use these methods.

3.1.8 Pickling

All pandas objects are equipped with `to_pickle` methods which use Python's `cPickle` module to save data structures to disk using the pickle format.

```
In [328]: df  
Out[328]:  
c1      a  
c2      b  d  
lvl1 lvl2  
a    c    1  5  
     d    2  6  
b    c    3  7  
     d    4  8  
  
In [329]: df.to_pickle('foo.pkl')
```

The `read_pickle` function in the `pandas` namespace can be used to load any pickled pandas object (or any other pickled object) from file:

```
In [330]: pd.read_pickle('foo.pkl')  
Out[330]:  
c1      a  
c2      b  d  
lvl1 lvl2  
a    c    1  5  
     d    2  6  
b    c    3  7  
     d    4  8
```

Warning: Loading pickled data received from untrusted sources can be unsafe.

See: <https://docs.python.org/3/library/pickle.html>

Warning: `read_pickle()` is only guaranteed backwards compatible back to pandas version 0.20.3

Compressed pickle files

`read_pickle()`, `DataFrame.to_pickle()` and `Series.to_pickle()` can read and write compressed pickle files. The compression types of gzip, bz2, xz are supported for reading and writing. The zip file format only supports reading and must contain only one data file to be read.

The compression type can be an explicit parameter or be inferred from the file extension. If ‘infer’, then use gzip, bz2, zip, or xz if filename ends in ‘.gz’, ‘.bz2’, ‘.zip’, or ‘.xz’, respectively.

```
In [331]: df = pd.DataFrame({
.....:     'A': np.random.randn(1000),
.....:     'B': 'foo',
.....:     'C': pd.date_range('20130101', periods=1000, freq='s')})
.....:

In [332]: df
Out[332]:
      A      B          C
0 -0.053113  foo 2013-01-01 00:00:00
1  0.348832  foo 2013-01-01 00:00:01
2 -0.162729  foo 2013-01-01 00:00:02
3 -1.269943  foo 2013-01-01 00:00:03
4 -0.481824  foo 2013-01-01 00:00:04
...
995 -1.001718  foo 2013-01-01 00:16:35
996 -0.471336  foo 2013-01-01 00:16:36
997 -0.071712  foo 2013-01-01 00:16:37
998  0.578273  foo 2013-01-01 00:16:38
999  0.595708  foo 2013-01-01 00:16:39

[1000 rows x 3 columns]
```

Using an explicit compression type:

```
In [333]: df.to_pickle("data.pkl.compress", compression="gzip")

In [334]: rt = pd.read_pickle("data.pkl.compress", compression="gzip")

In [335]: rt
Out[335]:
      A      B          C
0 -0.053113  foo 2013-01-01 00:00:00
1  0.348832  foo 2013-01-01 00:00:01
2 -0.162729  foo 2013-01-01 00:00:02
3 -1.269943  foo 2013-01-01 00:00:03
4 -0.481824  foo 2013-01-01 00:00:04
...
995 -1.001718  foo 2013-01-01 00:16:35
996 -0.471336  foo 2013-01-01 00:16:36
997 -0.071712  foo 2013-01-01 00:16:37
998  0.578273  foo 2013-01-01 00:16:38
999  0.595708  foo 2013-01-01 00:16:39

[1000 rows x 3 columns]
```

Inferring compression type from the extension:

```
In [336]: df.to_pickle("data.pkl.xz", compression="infer")

In [337]: rt = pd.read_pickle("data.pkl.xz", compression="infer")

In [338]: rt
Out[338]:
      A      B      C
0 -0.053113  foo 2013-01-01 00:00:00
1  0.348832  foo 2013-01-01 00:00:01
2 -0.162729  foo 2013-01-01 00:00:02
3 -1.269943  foo 2013-01-01 00:00:03
4 -0.481824  foo 2013-01-01 00:00:04
...
995 -1.001718  foo 2013-01-01 00:16:35
996 -0.471336  foo 2013-01-01 00:16:36
997 -0.071712  foo 2013-01-01 00:16:37
998  0.578273  foo 2013-01-01 00:16:38
999  0.595708  foo 2013-01-01 00:16:39

[1000 rows x 3 columns]
```

The default is to ‘infer’:

```
In [339]: df.to_pickle("data.pkl.gz")

In [340]: rt = pd.read_pickle("data.pkl.gz")

In [341]: rt
Out[341]:
      A      B      C
0 -0.053113  foo 2013-01-01 00:00:00
1  0.348832  foo 2013-01-01 00:00:01
2 -0.162729  foo 2013-01-01 00:00:02
3 -1.269943  foo 2013-01-01 00:00:03
4 -0.481824  foo 2013-01-01 00:00:04
...
995 -1.001718  foo 2013-01-01 00:16:35
996 -0.471336  foo 2013-01-01 00:16:36
997 -0.071712  foo 2013-01-01 00:16:37
998  0.578273  foo 2013-01-01 00:16:38
999  0.595708  foo 2013-01-01 00:16:39

[1000 rows x 3 columns]

In [342]: df["A"].to_pickle("s1.pkl.bz2")

In [343]: rt = pd.read_pickle("s1.pkl.bz2")

In [344]: rt
Out[344]:
0      -0.053113
1       0.348832
2      -0.162729
3      -1.269943
4      -0.481824
...
995   -1.001718
```

(continues on next page)

(continued from previous page)

```

996    -0.471336
997    -0.071712
998     0.578273
999     0.595708
Name: A, Length: 1000, dtype: float64

```

3.1.9 msgpack

pandas support for msgpack has been removed in version 1.0.0. It is recommended to use pyarrow for on-the-wire transmission of pandas objects.

Example pyarrow usage:

```

>>> import pandas as pd
>>> import pyarrow as pa
>>> df = pd.DataFrame({'A': [1, 2, 3]})
>>> context = pa.default_serialization_context()
>>> df_bytestring = context.serialize(df).to_buffer().to_pybytes()

```

For documentation on pyarrow, see [here](#).

3.1.10 HDF5 (PyTables)

HDFStore is a dict-like object which reads and writes pandas using the high performance HDF5 format using the excellent [PyTables](#) library. See the [cookbook](#) for some advanced strategies

Warning: pandas requires PyTables $\geq 3.0.0$. There is a indexing bug in PyTables < 3.2 which may appear when querying stores using an index. If you see a subset of results being returned, upgrade to PyTables ≥ 3.2 . Stores created previously will need to be rewritten using the updated version.

```

In [345]: store = pd.HDFStore('store.h5')

In [346]: print(store)
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5

```

Objects can be written to the file just like adding key-value pairs to a dict:

```

In [347]: index = pd.date_range('1/1/2000', periods=8)

In [348]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])

In [349]: df = pd.DataFrame(np.random.randn(8, 3), index=index,
   .....:             columns=['A', 'B', 'C'])
   ......

# store.put('s', s) is an equivalent method
In [350]: store['s'] = s

In [351]: store['df'] = df

```

(continues on next page)

(continued from previous page)

```
In [352]: store
Out[352]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5
```

In a current or later Python session, you can retrieve stored objects:

```
# store.get('df') is an equivalent method
In [353]: store['df']
Out[353]:
      A          B          C
2000-01-01  1.035711  0.940561 -0.591538
2000-01-02  0.190712  0.790743  1.139717
2000-01-03 -0.219782  0.578579  0.681221
2000-01-04  0.145058  2.277060 -1.684582
2000-01-05  0.118277  0.272245  1.207869
2000-01-06  0.093969 -0.024955 -1.266740
2000-01-07 -0.944512  0.834847  0.238307
2000-01-08 -1.613737  1.625981  0.378385

# dotted (attribute) access provides get as well
In [354]: store.df
Out[354]:
      A          B          C
2000-01-01  1.035711  0.940561 -0.591538
2000-01-02  0.190712  0.790743  1.139717
2000-01-03 -0.219782  0.578579  0.681221
2000-01-04  0.145058  2.277060 -1.684582
2000-01-05  0.118277  0.272245  1.207869
2000-01-06  0.093969 -0.024955 -1.266740
2000-01-07 -0.944512  0.834847  0.238307
2000-01-08 -1.613737  1.625981  0.378385
```

Deletion of the object specified by the key:

```
# store.remove('df') is an equivalent method
In [355]: del store['df']

In [356]: store
Out[356]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5
```

Closing a Store and using a context manager:

```
In [357]: store.close()

In [358]: store
Out[358]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5

In [359]: store.is_open
Out[359]: False

# Working with, and automatically closing the store using a context manager
In [360]: with pd.HDFStore('store.h5') as store:
```

(continues on next page)

(continued from previous page)

```
.....:     store.keys()
.....:
```

Read/write API

HDFStore supports a top-level API using `read_hdf` for reading and `to_hdf` for writing, similar to how `read_csv` and `to_csv` work.

```
In [361]: df_t1 = pd.DataFrame({'A': list(range(5)), 'B': list(range(5))})

In [362]: df_t1.to_hdf('store_t1.h5', 'table', append=True)

In [363]: pd.read_hdf('store_t1.h5', 'table', where=['index>2'])
Out[363]:
   A   B
3  3  3
4  4  4
```

HDFStore will by default not drop rows that are all missing. This behavior can be changed by setting `dropna=True`.

```
In [364]: df_with_missing = pd.DataFrame({'col1': [0, np.nan, 2],
                                         'col2': [1, np.nan, np.nan]})

In [365]: df_with_missing
Out[365]:
   col1  col2
0    0.0   1.0
1    NaN   NaN
2    2.0   NaN

In [366]: df_with_missing.to_hdf('file.h5', 'df_with_missing',
                               format='table', mode='w')
.....:

In [367]: pd.read_hdf('file.h5', 'df_with_missing')
Out[367]:
   col1  col2
0    0.0   1.0
1    NaN   NaN
2    2.0   NaN

In [368]: df_with_missing.to_hdf('file.h5', 'df_with_missing',
                               format='table', mode='w', dropna=True)
.....:

In [369]: pd.read_hdf('file.h5', 'df_with_missing')
Out[369]:
   col1  col2
0    0.0   1.0
1    NaN   NaN
2    2.0   NaN
```

Fixed format

The examples above show storing using `put`, which write the HDF5 to PyTables in a fixed array format, called the `fixed` format. These types of stores are **not** appendable once written (though you can simply remove them and rewrite). Nor are they `queryable`; they must be retrieved in their entirety. They also do not support dataframes with non-unique column names. The `fixed` format stores offer very fast writing and slightly faster reading than `table` stores. This format is specified by default when using `put` or `to_hdf` or by `format='fixed'` or `format='f'`.

Warning: A fixed format will raise a `TypeError` if you try to retrieve using a `where`:

```
>>> pd.DataFrame(np.random.randn(10, 2)).to_hdf('test_fixed.h5', 'df')
>>> pd.read_hdf('test_fixed.h5', 'df', where='index>5')
TypeError: cannot pass a where specification when reading a fixed format.
      this store must be selected in its entirety
```

Table format

HDFStore supports another PyTables format on disk, the `table` format. Conceptually a `table` is shaped very much like a DataFrame, with rows and columns. A `table` may be appended to in the same or other sessions. In addition, delete and query type operations are supported. This format is specified by `format='table'` or `format='t'` to append or `put` or `to_hdf`.

This format can be set as an option as well `pd.set_option('io.hdf.default_format', 'table')` to enable `put/append/to_hdf` to by default store in the `table` format.

```
In [370]: store = pd.HDFStore('store.h5')

In [371]: df1 = df[0:4]

In [372]: df2 = df[4:]

# append data (creates a table automatically)
In [373]: store.append('df', df1)

In [374]: store.append('df', df2)

In [375]: store
Out[375]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5

# select the entire object
In [376]: store.select('df')
Out[376]:
   A          B          C
2000-01-01  1.035711  0.940561 -0.591538
2000-01-02  0.190712  0.790743  1.139717
2000-01-03 -0.219782  0.578579  0.681221
2000-01-04  0.145058  2.277060 -1.684582
2000-01-05  0.118277  0.272245  1.207869
2000-01-06  0.093969 -0.024955 -1.266740
2000-01-07 -0.944512  0.834847  0.238307
2000-01-08 -1.613737  1.625981  0.378385

# the type of stored data
```

(continues on next page)

(continued from previous page)

```
In [377]: store.root.df._v_attrs.pandas_type
Out[377]: 'frame_table'
```

Note: You can also create a table by passing `format='table'` or `format='t'` to a put operation.

Hierarchical keys

Keys to a store can be specified as a string. These can be in a hierarchical path-name like format (e.g. `foo/bar/bah`), which will generate a hierarchy of sub-stores (or Groups in PyTables parlance). Keys can be specified without the leading `'/'` and are **always** absolute (e.g. `'foo'` refers to `'/foo'`). Removal operations can remove everything in the sub-store and **below**, so be *careful*.

```
In [378]: store.put('foo/bar/bah', df)

In [379]: store.append('food/orange', df)

In [380]: store.append('food/apple', df)

In [381]: store
Out[381]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5

# a list of keys are returned
In [382]: store.keys()
Out[382]: ['/df', '/food/apple', '/food/orange', '/foo/bar/bah']

# remove all nodes under this level
In [383]: store.remove('food')

In [384]: store
Out[384]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5
```

You can walk through the group hierarchy using the `walk` method which will yield a tuple for each group key along with the relative keys of its contents.

New in version 0.24.0.

```
In [385]: for (path, subgroups, subkeys) in store.walk():
....:     for subgroup in subgroups:
....:         print('GROUP: {}//{}'.format(path, subgroup))
....:         for subkey in subkeys:
....:             key = '/'.join([path, subkey])
....:             print('KEY: {}'.format(key))
....:             print(store.get(key))
....:
GROUP: /foo
KEY: /df
          A           B           C
2000-01-01  1.035711  0.940561 -0.591538
2000-01-02  0.190712  0.790743  1.139717
```

2000-01-08 -1.613737  1.625981  0.378385

```

Storing types

Storing mixed types in a table

Storing mixed-dtype data is supported. Strings are stored as a fixed-width using the maximum size of the appended column. Subsequent attempts at appending longer strings will raise a `ValueError`.

Passing `min_itemsizes={'values': size}` as a parameter to append will set a larger minimum for the string columns. Storing floats, strings, ints, bools, `datetime64` are currently supported. For string columns, passing `nan_rep = 'nan'` to append will change the default nan representation on disk (which converts to/from `np.nan`), this defaults to `nan`.

```
In [387]: df_mixed = pd.DataFrame({'A': np.random.randn(8),
.....:                               'B': np.random.randn(8),
.....:                               'C': np.array(np.random.randn(8), dtype='float32'),
.....:                               'string': 'string',
.....:                               'int': 1,
.....:                               'bool': True,
.....:                               'datetime64': pd.Timestamp('20010102')},
.....:                               index=list(range(8)))
.....:

In [388]: df_mixed.loc[df_mixed.index[3:5],
.....:                         ['A', 'B', 'string', 'datetime64']] = np.nan
.....:

In [389]: store.append('df_mixed', df_mixed, min_itemsizes={'values': 50})

In [390]: df_mixed1 = store.select('df_mixed')

In [391]: df_mixed1
Out[391]:
      A          B          C    string  int  bool  datetime64

Storing MultiIndex DataFrames

Storing MultiIndex DataFrames as tables is very similar to storing/selecting from homogeneous index DataFrames.

```

In [394]: index = pd.MultiIndex(levels=[['foo', 'bar', 'baz', 'qux'],
.....:                               ['one', 'two', 'three']],
.....:                               codes=[[0, 0, 0, 1, 1, 2, 2, 3, 3, 3],
.....:                                     [0, 1, 2, 0, 1, 1, 2, 0, 1, 2]],
.....:                               names=['foo', 'bar'])

In [395]: df_mi = pd.DataFrame(np.random.randn(10, 3), index=index,
.....:                           columns=['A', 'B', 'C'])
.....:

In [396]: df_mi
Out[396]:
          A         B         C
foo bar
foo one   -0.517581 -0.228428 -0.530004
          two   -0.980945 -1.844524 -0.064262
          three  1.023293  0.381220  0.986027

          two   -0.980945 -1.844524 -0.064262
          three  1.023293  0.381220  0.986027
bar one   1.450758 -0.529213  0.466885
          two   2.017039 -0.580386  0.336713

```

(continues on next page)

(continued from previous page)

```

baz two    -1.033958 -0.667998  0.053097
      three   1.451046  1.686829  1.378093
qux one    0.072875 -1.650570  1.020607
      two     1.979554  1.483921 -1.315492
      three   -2.224111 -1.913970  0.826827

# the levels are automatically included as data columns
In [399]: store.select('df_mi', 'foo=bar')
Out[399]:
          A         B         C
foo bar
bar one  1.450758 -0.529213  0.466885
      two  2.017039 -0.580386  0.336713

```

Note: The `index` keyword is reserved and cannot be used as a level name.

Querying

Querying a table

`select` and `delete` operations have an optional criterion that can be specified to select/delete only a subset of the data. This allows one to have a very large on-disk table and retrieve only a portion of the data.

A query is specified using the `Term` class under the hood, as a boolean expression.

- `index` and `columns` are supported indexers of DataFrames.
- if `data_columns` are specified, these can be used as additional indexers.
- level name in a MultiIndex, with default name `level_0`, `level_1`, ... if not provided.

Valid comparison operators are:

`=, ==, !=, >, >=, <, <=`

Valid boolean expressions are combined with:

- `|` : or
- `&` : and
- `(and)` : for grouping

These rules are similar to how boolean expressions are used in pandas for indexing.

Note:

- `=` will be automatically expanded to the comparison operator `==`
- `~` is the not operator, but can only be used in very limited circumstances
- If a list/tuple of expressions is passed they will be combined via `&`

The following are valid expressions:

- `'index >= date'`
- `"columns = ['A', 'D']"`

- "columns in ['A', 'D']"
- 'columns = A'
- 'columns == A'
- "~(columns = ['A', 'B'])"
- 'index > df.index[3] & string = "bar"'
- '(index > df.index[3] & index <= df.index[6]) | string = "bar"'
- "ts >= Timestamp('2012-02-01')"
- "major_axis>=20130101"

The `indexers` are on the left-hand side of the sub-expression:

`columns, major_axis, ts`

The right-hand side of the sub-expression (after a comparison operator) can be:

- functions that will be evaluated, e.g. `Timestamp('2012-02-01')`
- strings, e.g. `"bar"`
- date-like, e.g. `20130101`, or `"20130101"`
- lists, e.g. `['A', 'B']"`
- variables that are defined in the local names space, e.g. `date`

Note: Passing a string to a query by interpolating it into the query expression is not recommended. Simply assign the string of interest to a variable and use that variable in an expression. For example, do this

```
string = "HolyMoly"
store.select('df', 'index == string')
```

instead of this

```
string = "HolyMoly"
store.select('df', 'index == %s' % string)
```

The latter will **not** work and will raise a `SyntaxError`. Note that there's a single quote followed by a double quote in the `string` variable.

If you *must* interpolate, use the '`%r`' format specifier

```
store.select('df', 'index == %r' % string)
```

which will quote `string`.

Here are some examples:

```
In [400]: dfq = pd.DataFrame(np.random.randn(10, 4), columns=list('ABCD'),
.....:                               index=pd.date_range('20130101', periods=10))
.....:

In [401]: store.append('dfq', dfq, format='table', data_columns=True)
```

Use boolean expressions, with in-line function evaluation.

```
In [402]: store.select('dfq', "index>pd.Timestamp('20130104') & columns=['A', 'B']")
Out[402]:
```

	A	B
2013-01-05	0.513430	-1.804326
2013-01-06	-0.263806	-0.092597
2013-01-07	1.254664	0.067248
2013-01-08	1.145178	1.091743
2013-01-09	-0.304281	-0.164389
2013-01-10	-0.105767	0.972967

Use inline column reference.

```
In [403]: store.select('dfq', where="A>0 or C>0")
Out[403]:
```

	A	B	C	D
2013-01-01	-0.418406	0.439398	0.749766	-1.061173
2013-01-02	0.565172	0.859422	1.419105	0.598812
2013-01-04	0.609340	-0.837656	1.771917	-0.240180
2013-01-05	0.513430	-1.804326	-0.198967	-0.847306
2013-01-07	1.254664	0.067248	0.301278	0.786785
2013-01-08	1.145178	1.091743	-1.821309	1.496961
2013-01-09	-0.304281	-0.164389	0.212444	-0.335387
2013-01-10	-0.105767	0.972967	0.891833	0.154405

The `columns` keyword can be supplied to select a list of columns to be returned, this is equivalent to passing a '`columns=list_of_columns_to_filter`':

```
In [404]: store.select('df', "columns=['A', 'B']")
Out[404]:
```

	A	B
2000-01-01	1.035711	0.940561
2000-01-02	0.190712	0.790743
2000-01-03	-0.219782	0.578579
2000-01-04	0.145058	2.277060
2000-01-05	0.118277	0.272245
2000-01-06	0.093969	-0.024955
2000-01-07	-0.944512	0.834847
2000-01-08	-1.613737	1.625981

`start` and `stop` parameters can be specified to limit the total search space. These are in terms of the total number of rows in a table.

Note: `select` will raise a `ValueError` if the query expression has an unknown variable reference. Usually this means that you are trying to select on a column that is **not** a `data_column`.

`select` will raise a `SyntaxError` if the query expression is not valid.

Query timedelta64[ns]

You can store and query using the `timedelta64[ns]` type. Terms can be specified in the format: `<float>(<unit>)`, where float may be signed (and fractional), and unit can be `D`, `s`, `ms`, `us`, `ns` for the `timedelta`. Here's an example:

```
In [405]: from datetime import timedelta

In [406]: dftd = pd.DataFrame({ 'A': pd.Timestamp('20130101'),
.....:                               'B': [pd.Timestamp('20130101') + timedelta(days=i,
.....:                                               seconds=10)
.....:                               for i in range(10)]})
.....:

In [407]: dftd['C'] = dftd['A'] - dftd['B']

In [408]: dftd
Out[408]:
      A            B            C
0 2013-01-01 00:00:10 -1 days +23:59:50
1 2013-01-01 00:00:10 -2 days +23:59:50
2 2013-01-01 00:00:10 -3 days +23:59:50
3 2013-01-01 00:00:10 -4 days +23:59:50

```

Query MultiIndex

Selecting from a MultiIndex can be achieved by using the name of the level.

```
In [411]: df_mi.index.names
Out[411]: FrozenList(['foo', 'bar'])

In [412]: store.select('df_mi', "foo=bar and bar=two")
Out[412]:
      A            B            C
foo bar
baz two -1.033958 -0.667998  0.053097
```

If the MultiIndex levels names are `None`, the levels are automatically made available via the `level_n` keyword

with `n` the level of the MultiIndex you want to select from.

```
In [413]: index = pd.MultiIndex(
.....:     levels=[["foo", "bar", "baz", "qux"], ["one", "two", "three"]],
.....:     codes=[[0, 0, 0, 1, 1, 2, 2, 3, 3, 3], [0, 1, 2, 0, 1, 1, 2, 0, 1, 2]],
.....: )
.....:

In [414]: df_mi_2 = pd.DataFrame(np.random.randn(10, 3),
.....:                           index=index, columns=["A", "B", "C"])
.....:

In [415]: df_mi_2
Out[415]:
      A          B          C
foo one  0.305697 -0.034129  0.406960
       two  1.686468 -0.335278  0.022043
       three  0.659023  0.233250  0.539565
bar one  -2.207606  0.062355 -0.216954
       two  1.273459  0.535017  0.642836
baz two  -0.905166 -1.057972 -1.660837
       three  0.951853  0.410201  1.177667
qux one   1.399153 -0.427863  0.321643
       two   2.233833  0.030886 -1.462611
       three -0.758710 -0.314791 -0.067256

In [416]: store.append("df_mi_2", df_mi_2)

# the levels are automatically included as data columns with keyword level_n
In [417]: store.select("df_mi_2", "level_0=foo and level_1=two")
Out[417]:
      A          B          C
foo two  1.686468 -0.335278  0.022043
```

Indexing

You can create/modify an index for a table with `create_table_index` after data is already in the table (after and `append/put` operation). Creating a table index is **highly** encouraged. This will speed your queries a great deal when you use a `select` with the indexed dimension as the `where`.

Note: Indexes are automagically created on the indexables and any data columns you specify. This behavior can be turned off by passing `index=False` to `append`.

```
# we have automagically already created an index (in the first section)
In [418]: i = store.root.df.table.cols.index.index

In [419]: i.optlevel, i.kind
Out[419]: (6, 'medium')

# change an index by passing new parameters
In [420]: store.create_table_index('df', optlevel=9, kind='full')

In [421]: i = store.root.df.table.cols.index.index
```

(continues on next page)

(continued from previous page)

```
In [422]: i.optlevel, i.kind
Out[422]: (9, 'full')
```

Oftentimes when appending large amounts of data to a store, it is useful to turn off index creation for each append, then recreate at the end.

```
In [423]: df_1 = pd.DataFrame(np.random.randn(10, 2), columns=list('AB'))

In [424]: df_2 = pd.DataFrame(np.random.randn(10, 2), columns=list('AB'))

In [425]: st = pd.HDFStore('appends.h5', mode='w')

In [426]: st.append('df', df_1, data_columns=['B'], index=False)

In [427]: st.append('df', df_2, data_columns=['B'], index=False)

In [428]: st.get_storer('df').table
Out[428]:
/df/table (Table(20,)) ''
description := {
    "index": Int64Col(shape=(), dflt=0, pos=0),
    "values_block_0": Float64Col(shape=(1,), dflt=0.0, pos=1),
    "B": Float64Col(shape=(), dflt=0.0, pos=2)}
byteorder := 'little'
chunkshape := (2730,)
```

Then create the index when finished appending.

```
In [429]: st.create_table_index('df', columns=['B'], optlevel=9, kind='full')

In [430]: st.get_storer('df').table
Out[430]:
/df/table (Table(20,)) ''
description := {
    "index": Int64Col(shape=(), dflt=0, pos=0),
    "values_block_0": Float64Col(shape=(1,), dflt=0.0, pos=1),
    "B": Float64Col(shape=(), dflt=0.0, pos=2)}
byteorder := 'little'
chunkshape := (2730,)
autoindex := True
colindexes := {
    "B": Index(9, full, shuffle, zlib(1)).is_csi=True}

In [431]: st.close()
```

See [here](#) for how to create a completely-sorted-index (CSI) on an existing store.

Query via data columns

You can designate (and index) certain columns that you want to be able to perform queries (other than the *indexable* columns, which you can always query). For instance say you want to perform this common operation, on-disk, and return just the frame that matches this query. You can specify `data_columns = True` to force all columns to be `data_columns`.

```
In [432]: df_dc = df.copy()

In [433]: df_dc['string'] = 'foo'

In [434]: df_dc.loc[df_dc.index[4:6], 'string'] = np.nan

In [435]: df_dc.loc[df_dc.index[7:9], 'string'] = 'bar'

In [436]: df_dc['string2'] = 'cool'

In [437]: df_dc.loc[df_dc.index[1:3], ['B', 'C']] = 1.0

In [438]: df_dc
Out[438]:
          A         B         C  string string2

    "B": Index(6, medium, shuffle, zlib(1)).is_csi=False,
    "C": Index(6, medium, shuffle, zlib(1)).is_csi=False,
    "string": Index(6, medium, shuffle, zlib(1)).is_csi=False,
    "string2": Index(6, medium, shuffle, zlib(1)).is_csi=False}

```

There is some performance degradation by making lots of columns into *data columns*, so it is up to the user to designate these. In addition, you cannot change data columns (nor indexables) after the first append/put operation (Of course you can simply read in the data and create a new table!).

Iterator

You can pass iterator=True or chunksize=number_in_a_chunk to select and select_as_multiple to return an iterator on the results. The default is 50,000 rows returned in a chunk.

```

In [444]: for df in store.select('df', chunksize=3):
.....:     print(df)
.....:
          A           B           C
2000-01-01  1.035711  0.940561 -0.591538
2000-01-02  0.190712  0.790743  1.139717
2000-01-03 -0.219782  0.578579  0.681221
          A           B           C
2000-01-04  0.145058  2.277060 -1.684582
2000-01-05  0.118277  0.272245  1.207869
2000-01-06  0.093969 -0.024955 -1.266740
          A           B           C
2000-01-07 -0.944512  0.834847  0.238307
2000-01-08 -1.613737  1.625981  0.378385

```

Note: You can also use the iterator with read_hdf which will open, then automatically close the store when finished iterating.

```
for df in pd.read_hdf('store.h5', 'df', chunkszie=3):
    print(df)
```

Note, that the `chunksize` keyword applies to the `source` rows. So if you are doing a query, then the `chunksize` will subdivide the total rows in the table and the query applied, returning an iterator on potentially unequal sized chunks.

Here is a recipe for generating a query and using it to create equal sized return chunks.

```
In [445]: dfeq = pd.DataFrame({'number': np.arange(1, 11)})

In [446]: dfeq
Out[446]:
   number
0        1
1        2
2        3
3        4
4        5
5        6
6        7
7        8
8        9
9       10

In [447]: store.append('dfeq', dfeq, data_columns=['number'])

In [448]: def chunks(l, n):
.....:     return [l[i:i + n] for i in range(0, len(l), n)]
.....:

In [449]: evens = [2, 4, 6, 8, 10]

In [450]: coordinates = store.select_as_coordinates('dfeq', 'number=evens')

In [451]: for c in chunks(coordinates, 2):
.....:     print(store.select('dfeq', where=c))
.....:
   number
1        2
3        4
   number
5        6
7        8
   number
9       10
```

Advanced queries

Select a single column

To retrieve a single indexable or data column, use the method `select_column`. This will, for example, enable you to get the index very quickly. These return a `Series` of the result, indexed by the row number. These do not currently accept the `where` selector.

```
In [452]: store.select_column('df_dc', 'index')
Out[452]:
0    2000-01-01
1    2000-01-02
2    2000-01-03
3    2000-01-04
4    2000-01-05
5    2000-01-06
6    2000-01-07
7    2000-01-08
Name: index, dtype: datetime64[ns]

In [453]: store.select_column('df_dc', 'string')
Out[453]:
0    foo
1    foo
2    foo
3    foo
4    NaN
5    NaN
6    foo
7    bar
Name: string, dtype: object
```

Selecting coordinates

Sometimes you want to get the coordinates (a.k.a the index locations) of your query. This returns an `Int64Index` of the resulting locations. These coordinates can also be passed to subsequent `where` operations.

```
In [454]: df_coord = pd.DataFrame(np.random.randn(1000, 2),
.....:                               index=pd.date_range('20000101', periods=1000))
.....:

In [455]: store.append('df_coord', df_coord)

In [456]: c = store.select_as_coordinates('df_coord', 'index > 20020101')

In [457]: c
Out[457]:
Int64Index([732, 733, 734, 735, 736, 737, 738, 739, 740, 741,
            ...
            990, 991, 992, 993, 994, 995, 996, 997, 998, 999],
           dtype='int64', length=268)

In [458]: store.select('df_coord', where=c)
Out[458]:
```

0 1

[268 rows x 2 columns]

Selecting using a where mask

Sometime your query can involve creating a list of rows to select. Usually this mask would be a resulting index from an indexing operation. This example selects the months of a datetimeindex which are 5.

In [459]:	df_mask = pd.DataFrame(np.random.randn(1000, 2),::	index=pd.date_range('20000101', periods=1000))
In [460]:	store.append('df_mask', df_mask)	
In [461]:	c = store.select_column('df_mask', 'index')	
In [462]:	where = c[pd.DatetimeIndex(c).month == 5].index	
In [463]:	store.select('df_mask', where=where)	
Out[463]:		
	0 1 2000-05-01 -0.496308 0.104795 2000-05-02 -1.274529 -0.385938 2000-05-03 0.154634 -0.961341 2000-05-04 0.847659 -0.998979 2000-05-05 -0.357585 0.372744 2002-05-27 0.653012 0.285638 2002-05-28 1.196511 -1.093342 2002-05-29 -1.369165 1.178020 2002-05-30 -0.079145 0.676504 2002-05-31 -1.082410 0.082034	
	[93 rows x 2 columns]	

Storer object

If you want to inspect the stored object, retrieve via `get_storer`. You could use this programmatically to say get the number of rows in an object.

```
In [464]: store.get_storer('df_dc').nrows
Out[464]: 8
```

Multiple table queries

The methods `append_to_multiple` and `select_as_multiple` can perform appending/selecting from multiple tables at once. The idea is to have one table (call it the selector table) that you index most/all of the columns, and perform your queries. The other table(s) are data tables with an index matching the selector table's index. You can then perform a very fast query on the selector table, yet get lots of data back. This method is similar to having a very wide table, but enables more efficient queries.

The `append_to_multiple` method splits a given single DataFrame into multiple tables according to `d`, a dictionary that maps the table names to a list of ‘columns’ you want in that table. If `None` is used in place of a list, that table will have the remaining unspecified columns of the given DataFrame. The argument `selector` defines which table is the selector table (which you can make queries from). The argument `dropna` will drop rows from the input DataFrame to ensure tables are synchronized. This means that if a row for one of the tables being written to is entirely `np.NaN`, that row will be dropped from all tables.

If `dropna` is False, **THE USER IS RESPONSIBLE FOR SYNCHRONIZING THE TABLES**. Remember that entirely `np.NaN` rows are not written to the HDFStore, so if you choose to call `dropna=False`, some tables may have more rows than others, and therefore `select_as_multiple` may not work or it may return unexpected results.

```
In [465]: df_mt = pd.DataFrame(np.random.randn(8, 6),
.....:                               index=pd.date_range('1/1/2000', periods=8),
.....:                               columns=['A', 'B', 'C', 'D', 'E', 'F'])
.....:

In [466]: df_mt['foo'] = 'bar'

In [467]: df_mt.loc[df_mt.index[1], ('A', 'B')] = np.nan

# you can also create the tables individually
In [468]: store.append_to_multiple({'df1_mt': ['A', 'B'], 'df2_mt': None},
.....:                               df_mt, selector='df1_mt')
.....:

In [469]: store
Out[469]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5

# individual tables were created
In [470]: store.select('df1_mt')

Delete from a table

You can delete from a table selectively by specifying a `where`. In deleting rows, it is important to understand the PyTables deletes rows by erasing the rows, then **moving** the following data. Thus deleting can potentially be a very expensive operation depending on the orientation of your data. To get optimal performance, it's worthwhile to have the dimension you are deleting be the first of the `indexables`.

Data is ordered (on the disk) in terms of the `indexables`. Here's a simple use case. You store panel-type data, with dates in the `major_axis` and ids in the `minor_axis`. The data is then interleaved like this:

- **date_1**
 - `id_1`
 - `id_2`
 - .
 - `id_n`
- **date_2**
 - `id_1`
 - .
 - `id_n`

It should be clear that a delete operation on the `major_axis` will be fairly quick, as one chunk is removed, then the following data moved. On the other hand a delete operation on the `minor_axis` will be very expensive. In this case it would almost certainly be faster to rewrite the table using a `where` that selects all but the missing data.

Warning: Please note that HDF5 **DOES NOT RECLAIM SPACE** in the h5 files automatically. Thus, repeatedly deleting (or removing nodes) and adding again, **WILL TEND TO INCREASE THE FILE SIZE**.

To repack and clean the file, use [ptrepack](#).

Notes & caveats

Compression

PyTables allows the stored data to be compressed. This applies to all kinds of stores, not just tables. Two parameters are used to control compression: `complevel` and `complib`.

complevel specifies if and how hard data is to be compressed. `complevel=0` and `complevel=None` disables compression and `0 < complevel < 10` enables compression.

complib specifies which compression library to use. If nothing is specified the default library `zlib` is used. A compression library usually optimizes for either good compression rates or speed and the results will depend on the type of data. Which type of compression to choose depends on your specific needs and data. The list of supported compression libraries:

- `zlib`: The default compression library. A classic in terms of compression, achieves good compression rates but is somewhat slow.
- `lzo`: Fast compression and decompression.
- `bzip2`: Good compression rates.
- `blosc`: Fast compression and decompression.

Support for alternative blosc compressors:

- `blosc:blosclz`: This is the default compressor for `blosc`
- `blosc:lz4`: A compact, very popular and fast compressor.
- `blosc:lz4hc`: A tweaked version of LZ4, produces better compression ratios at the expense of speed.
- `blosc:snappy`: A popular compressor used in many places.
- `blosc:zlib`: A classic; somewhat slower than the previous ones, but achieving better compression ratios.
- `blosc:zstd`: An extremely well balanced codec; it provides the best compression ratios among the others above, and at reasonably fast speed.

If `complib` is defined as something other than the listed libraries a `ValueError` exception is issued.

Note: If the library specified with the `complib` option is missing on your platform, compression defaults to `zlib` without further ado.

Enable compression for all objects within the file:

```
store_compressed = pd.HDFStore('store_compressed.h5', complevel=9,
                                complib='blosc:blosclz')
```

Or on-the-fly compression (this only applies to tables) in stores where compression is not enabled:

```
store.append('df', df, complib='zlib', complevel=5)
```

ptrepack

PyTables offers better write performance when tables are compressed after they are written, as opposed to turning on compression at the very beginning. You can use the supplied PyTables utility `ptrepack`. In addition, `ptrepack` can change compression levels after the fact.

```
ptrepack --chunkshape=auto --propindexes --complevel=9 --complib=blosc in.h5 out.h5
```

Furthermore `ptrepack in.h5 out.h5` will *repack* the file to allow you to reuse previously deleted space. Alternatively, one can simply remove the file and write again, or use the `copy` method.

Caveats

Warning: `HDFStore` is **not-threadsafe for writing**. The underlying PyTables only supports concurrent reads (via threading or processes). If you need reading and writing *at the same time*, you need to serialize these operations in a single thread in a single process. You will corrupt your data otherwise. See the ([GH2397](#)) for more information.

- If you use locks to manage write access between multiple processes, you may want to use `fsync()` before releasing write locks. For convenience you can use `store.flush(fsync=True)` to do this for you.
- Once a `table` is created columns (DataFrame) are fixed; only exactly the same columns can be appended
- Be aware that timezones (e.g., `pytz.timezone('US/Eastern')`) are not necessarily equal across timezone versions. So if data is localized to a specific timezone in the HDFStore using one version of a timezone library and that data is updated with another version, the data will be converted to UTC since these timezones are not considered equal. Either use the same version of timezone library or use `tz_convert` with the updated timezone definition.

Warning: PyTables will show a `NaturalNameWarning` if a column name cannot be used as an attribute selector. *Natural* identifiers contain only letters, numbers, and underscores, and may not begin with a number. Other identifiers cannot be used in a `where` clause and are generally a bad idea.

DataTypes

`HDFStore` will map an object `dtype` to the PyTables underlying `dtype`. This means the following types are known to work:

Type	Represents missing values
<code>floating</code> : <code>float64</code> , <code>float32</code> , <code>float16</code>	<code>np.nan</code>
<code>integer</code> : <code>int64</code> , <code>int32</code> , <code>int8</code> , <code>uint64</code> , <code>uint32</code> , <code>uint8</code>	
<code>boolean</code>	
<code>datetime64[ns]</code>	<code>NaT</code>
<code>timedelta64[ns]</code>	<code>NaT</code>
<code>categorical</code> : see the section below	
<code>object</code> : strings	<code>np.nan</code>

unicode columns are not supported, and **WILL FAIL**.

Categorical data

You can write data that contains category dtypes to a HDFStore. Queries work the same as if it was an object array. However, the category dtypes data is stored in a more efficient manner.

```
In [473]: dfcat = pd.DataFrame({'A': pd.Series(list('aabbcdba')).astype('category'),  
.....: 'B': np.random.randn(8)})  
.....:  
  
In [474]: dfcat  
Out[474]:  
      A          B  
0   a -0.401277  
1   a -0.461935  
2   b  1.336594  
3   b -1.311606  
4   c  0.274135  
5   d  0.431250  
6   b -1.784013  
7   a  0.267158  
  
In [475]: dfcat.dtypes  
Out[475]:  
A    category  
B    float64  
dtype: object  
  
In [476]: cstore = pd.HDFStore('cats.h5', mode='w')  
  
In [477]: cstore.append('dfcat', dfcat, format='table', data_columns=['A'])  
  
In [478]: result = cstore.select('dfcat', where="A in ['b', 'c']")  
  
In [479]: result  
Out[479]:  
      A          B  
2   b  1.336594  
3   b -1.311606  
4   c  0.274135  
6   b -1.784013  
  
In [480]: result.dtypes  
Out[480]:  
A    category  
B    float64  
dtype: object
```

String columns

min_itemsize

The underlying implementation of HDFStore uses a fixed column width (itemsize) for string columns. A string column itemsize is calculated as the maximum of the length of data (for that column) that is passed to the HDFStore, **in the first append**. Subsequent appends, may introduce a string for a column **larger** than the column can hold, an Exception will be raised (otherwise you could have a silent truncation of these columns, leading to loss of information). In the future we may relax this and allow a user-specified truncation to occur.

Pass min_itemsize on the first table creation to a-priori specify the minimum length of a particular string column. min_itemsize can be an integer, or a dict mapping a column name to an integer. You can pass values as a key to allow all *indexables* or *data_columns* to have this min_itemsize.

Passing a min_itemsize dict will cause all passed columns to be created as *data_columns* automatically.

Note: If you are not passing any *data_columns*, then the min_itemsize will be the maximum of the length of any string passed

```
In [481]: dfs = pd.DataFrame({'A': 'foo', 'B': 'bar'}, index=list(range(5)))

In [482]: dfs
Out[482]:
   A      B
0  foo    bar
1  foo    bar
2  foo    bar
3  foo    bar
4  foo    bar

# A and B have a size of 30
In [483]: store.append('dfs', dfs, min_itemsize=30)

In [484]: store.get_storer('dfs').table
Out[484]:
/dfs/table (Table(5,)) ''
description := {
  "index": Int64Col(shape=(), dflt=0, pos=0),
  "values_block_0": StringCol(itemsize=30, shape=(2,), dflt=b'', pos=1)}
byteorder := 'little'
chunkshape := (963,)
autoindex := True
colindexes := {
  "index": Index(6, medium, shuffle, zlib(1)).is_csi=False}

# A is created as a data_column with a size of 30
# B is size is calculated
In [485]: store.append('dfs2', dfs, min_itemsize={'A': 30})

In [486]: store.get_storer('dfs2').table
Out[486]:
/dfs2/table (Table(5,)) ''
description := {
  "index": Int64Col(shape=(), dflt=0, pos=0),
  "values_block_0": StringCol(itemsize=3, shape=(1,), dflt=b'', pos=1),
  "A": StringCol(itemsize=30, shape=(), dflt=b'', pos=2)}
```

(continues on next page)

(continued from previous page)

```
byteorder := 'little'
chunkshape := (1598,)
autoindex := True
colindexes := {
    "index": Index(6, medium, shuffle, zlib(1)).is_csi=False,
    "A": Index(6, medium, shuffle, zlib(1)).is_csi=False}
```

nan_rep

String columns will serialize a np.nan (a missing value) with the nan_rep string representation. This defaults to the string value nan. You could inadvertently turn an actual nan value into a missing value.

```
In [487]: dfss = pd.DataFrame({'A': ['foo', 'bar', 'nan']})
```

```
In [488]: dfss
```

```
Out[488]:
```

```
    A
0  foo
1  bar
2  nan
```

```
In [489]: store.append('dfss', dfss)
```

```
In [490]: store.select('dfss')
```

```
Out[490]:
```

```
    A
0  foo
1  bar
2  NaN
```

```
# here you need to specify a different nan rep
```

```
In [491]: store.append('dfss2', dfss, nan_rep='_nan_')
```

```
In [492]: store.select('dfss2')
```

```
Out[492]:
```

```
    A
0  foo
1  bar
2  nan
```

External compatibility

HDFStore writes table format objects in specific formats suitable for producing loss-less round trips to pandas objects. For external compatibility, HDFStore can read native PyTables format tables.

It is possible to write an HDFStore object that can easily be imported into R using the rhdf5 library (Package website). Create a table format store like this:

```
In [493]: df_for_r = pd.DataFrame({"first": np.random.rand(100),
.....:                               "second": np.random.rand(100),
.....:                               "class": np.random.randint(0, 2, (100, ))},
.....:                               index=range(100))
```

```
In [494]: df_for_r.head()
```

(continues on next page)

(continued from previous page)

```
Out[494]:
      first    second  class
0  0.021537  0.840277     1
1  0.204310  0.884547     1
2  0.535125  0.183768     1
3  0.250653  0.315208     1
4  0.608309  0.535945     0

In [495]: store_export = pd.HDFStore('export.h5')

In [496]: store_export.append('df_for_r', df_for_r, data_columns=df_dc.columns)

In [497]: store_export
Out[497]:
<class 'pandas.io.pytables.HDFStore'>
File path: export.h5
```

In R this file can be read into a `data.frame` object using the `rhdf5` library. The following example function reads the corresponding column names and data values from the values and assembles them into a `data.frame`:

```
# Load values and column names for all datasets from corresponding nodes and
# insert them into one data.frame object.

library(rhdf5)

loadhdf5data <- function(h5File) {

  listing <- h5ls(h5File)
  # Find all data nodes, values are stored in *_values and corresponding column
  # titles in *_items
  data_nodes <- grep("_values", listing$name)
  name_nodes <- grep("_items", listing$name)
  data_paths = paste(listing$group[data_nodes], listing$name[data_nodes], sep = "/")
  name_paths = paste(listing$group[name_nodes], listing$name[name_nodes], sep = "/")
  columns = list()
  for (idx in seq(data_paths)) {
    # NOTE: matrices returned by h5read have to be transposed to obtain
    # required Fortran order!
    data <- data.frame(t(h5read(h5File, data_paths[idx])))
    names <- t(h5read(h5File, name_paths[idx]))
    entry <- data.frame(data)
    colnames(entry) <- names
    columns <- append(columns, entry)
  }

  data <- data.frame(columns)

  return(data)
}
```

Now you can import the DataFrame into R:

```
> data = loadhdf5data("transfer.hdf5")
> head(data)
      first    second  class
1  0.4170220047  0.3266449     0
```

(continues on next page)

(continued from previous page)

2	0.7203244934	0.5270581	0
3	0.0001143748	0.8859421	1
4	0.3023325726	0.3572698	1
5	0.1467558908	0.9085352	1
6	0.0923385948	0.6233601	1

Note: The R function lists the entire HDF5 file's contents and assembles the `data.frame` object from all matching nodes, so use this only as a starting point if you have stored multiple `DataFrame` objects to a single HDF5 file.

Performance

- `tables` format come with a writing performance penalty as compared to `fixed` stores. The benefit is the ability to append/delete and query (potentially very large amounts of data). Write times are generally longer as compared with regular stores. Query times can be quite fast, especially on an indexed axis.
- You can pass `chunksize=<int>` to `append`, specifying the write chunksize (default is 50000). This will significantly lower your memory usage on writing.
- You can pass `expectedrows=<int>` to the first `append`, to set the TOTAL number of rows that PyTables will expect. This will optimize read/write performance.
- Duplicate rows can be written to `tables`, but are filtered out in selection (with the last items being selected; thus a table is unique on major, minor pairs)
- A `PerformanceWarning` will be raised if you are attempting to store types that will be pickled by PyTables (rather than stored as endemic types). See [Here](#) for more information and some solutions.

3.1.11 Feather

Feather provides binary columnar serialization for data frames. It is designed to make reading and writing data frames efficient, and to make sharing data across data analysis languages easy.

Feather is designed to faithfully serialize and de-serialize `DataFrames`, supporting all of the pandas dtypes, including extension dtypes such as categorical and datetime with tz.

Several caveats.

- This is a newer library, and the format, though stable, is not guaranteed to be backward compatible to the earlier versions.
- The format will NOT write an `Index`, or `MultiIndex` for the `DataFrame` and will raise an error if a non-default one is provided. You can `.reset_index()` to store the index or `.reset_index(drop=True)` to ignore it.
- Duplicate column names and non-string columns names are not supported
- Non supported types include `Period` and actual Python object types. These will raise a helpful error message on an attempt at serialization.

See the [Full Documentation](#).

```
In [498]: df = pd.DataFrame({'a': list('abc'),
.....: 'b': list(range(1, 4)),
.....: 'c': np.arange(3, 6).astype('u1'),
.....: 'd': np.arange(4.0, 7.0, dtype='float64'),
```

(continues on next page)

(continued from previous page)

```

3.1.12 Parquet

New in version 0.21.0.

[Apache Parquet](#) provides a partitioned binary columnar serialization for data frames. It is designed to make reading and writing data frames efficient, and to make sharing data across data analysis languages easy. Parquet can use a variety of compression techniques to shrink the file size as much as possible while still maintaining good read performance.

Parquet is designed to faithfully serialize and de-serialize DataFrame s, supporting all of the pandas dtypes, including extension dtypes such as datetime with tz.

Several caveats.

- Duplicate column names and non-string columns names are not supported.
- The pyarrow engine always writes the index to the output, but fastparquet only writes non-default indexes. This extra column can cause problems for non-Pandas consumers that are not expecting it. You can force including or omitting indexes with the index argument, regardless of the underlying engine.
- Index level names, if specified, must be strings.
- In the pyarrow engine, categorical dtypes for non-string types can be serialized to parquet, but will de-serialize as their primitive dtype.
- The pyarrow engine preserves the ordered flag of categorical dtypes with string types. fastparquet does not preserve the ordered flag.
- Non supported types include Interval and actual Python object types. These will raise a helpful error message on an attempt at serialization. Period type is supported with pyarrow >= 0.16.0.
- The pyarrow engine preserves extension data types such as the nullable integer and string data type (requiring pyarrow >= 0.16.0, and requiring the extension type to implement the needed protocols, see the [extension types documentation](#)).

You can specify an engine to direct the serialization. This can be one of pyarrow, or fastparquet, or auto. If the engine is NOT specified, then the pd.options.io.parquet.engine option is checked; if this is also auto, then pyarrow is tried, and falling back to fastparquet.

See the documentation for [pyarrow](#) and [fastparquet](#).

Note: These engines are very similar and should read/write nearly identical parquet format files. Currently pyarrow does not support timedelta data, fastparquet>=0.1.4 supports timezone aware datetimes. These libraries differ by having different underlying dependencies (fastparquet by using numba, while pyarrow uses a c-library).

```

In [505]: df = pd.DataFrame({'a': list('abc'),
.....:                  'b': list(range(1, 4)),
.....:                  'c': np.arange(3, 6).astype('u1'),
.....:                  'd': np.arange(4.0, 7.0, dtype='float64'),

```

In [515]: result.dtypes
Out[515]:
a    object
b    int64
dtype: object
```

Handling indexes

Serializing a DataFrame to parquet may include the implicit index as one or more columns in the output file. Thus, this code:

```
In [516]: df = pd.DataFrame({'a': [1, 2], 'b': [3, 4]})

In [517]: df.to_parquet('test.parquet', engine='pyarrow')
```

creates a parquet file with *three* columns if you use pyarrow for serialization: a, b, and `__index_level_0__`. If you're using fastparquet, the index `may or may not` be written to the file.

This unexpected extra column causes some databases like Amazon Redshift to reject the file, because that column doesn't exist in the target table.

If you want to omit a dataframe's indexes when writing, pass `index=False` to `to_parquet()`:

```
In [518]: df.to_parquet('test.parquet', index=False)
```

This creates a parquet file with just the two expected columns, a and b. If your DataFrame has a custom index, you won't get it back when you load this file into a DataFrame.

Passing `index=True` will *always* write the index, even if that's not the underlying engine's default behavior.

Partitioning Parquet files

New in version 0.24.0.

Parquet supports partitioning of data based on the values of one or more columns.

```
In [519]: df = pd.DataFrame({'a': [0, 0, 1, 1], 'b': [0, 1, 0, 1]})

In [520]: df.to_parquet(path='test', engine='pyarrow',
.....:                     partition_cols=['a'], compression=None)
.....:
```

The `path` specifies the parent directory to which data will be saved. The `partition_cols` are the column names by which the dataset will be partitioned. Columns are partitioned in the order they are given. The partition splits are determined by the unique values in the partition columns. The above example creates a partitioned dataset that may look like:

```
test
└── a=0
    └── 0bac803e32dc42ae83fddfd029cbdebc.parquet
```

(continues on next page)

(continued from previous page)

```

└── ...
    a=1
    └── e6ab24a4f45147b49b54a662f0c412a3.parquet
        ...

```

3.1.13 ORC

New in version 1.0.0.

Similar to the [parquet](#) format, the ORC Format is a binary columnar serialization for data frames. It is designed to make reading data frames efficient. Pandas provides *only* a reader for the ORC format, `read_orc()`. This requires the [pyarrow](#) library.

3.1.14 SQL queries

The `pandas.io.sql` module provides a collection of query wrappers to both facilitate data retrieval and to reduce dependency on DB-specific API. Database abstraction is provided by SQLAlchemy if installed. In addition you will need a driver library for your database. Examples of such drivers are [psycopg2](#) for PostgreSQL or [pymysql](#) for MySQL. For [SQLite](#) this is included in Python's standard library by default. You can find an overview of supported drivers for each SQL dialect in the [SQLAlchemy docs](#).

If SQLAlchemy is not installed, a fallback is only provided for sqlite (and for mysql for backwards compatibility, but this is deprecated and will be removed in a future version). This mode requires a Python database adapter which respect the [Python DB-API](#).

See also some [cookbook examples](#) for some advanced strategies.

The key functions are:

<code>read_sql_table(table_name, con[, schema, ...])</code>	Read SQL database table into a DataFrame.
<code>read_sql_query(sql, con[, index_col, ...])</code>	Read SQL query into a DataFrame.
<code>read_sql(sql, con[, index_col, ...])</code>	Read SQL query or database table into a DataFrame.
<code>DataFrame.to_sql(self, name, con[, schema, ...])</code>	Write records stored in a DataFrame to a SQL database.

Note: The function `read_sql()` is a convenience wrapper around `read_sql_table()` and `read_sql_query()` (and for backward compatibility) and will delegate to specific function depending on the provided input (database table name or sql query). Table names do not need to be quoted if they have special characters.

In the following example, we use the [SQLite](#) SQL database engine. You can use a temporary SQLite database where data are stored in “memory”.

To connect with SQLAlchemy you use the `create_engine()` function to create an engine object from database URI. You only need to create the engine once per database you are connecting to. For more information on `create_engine()` and the URI formatting, see the examples below and the SQLAlchemy [documentation](#)

```

In [521]: from sqlalchemy import create_engine
          # Create your engine.
In [522]: engine = create_engine('sqlite:///memory:')

```

If you want to manage your own connections you can pass one of those instead:

```
with engine.connect() as conn, conn.begin():
    data = pd.read_sql_table('data', conn)
```

Writing DataFrames

Assuming the following data is in a DataFrame `data`, we can insert it into the database using `to_sql()`.

id	Date	Col_1	Col_2	Col_3
26	2012-10-18	X	25.7	True
42	2012-10-19	Y	-12.4	False
63	2012-10-20	Z	5.73	True

```
In [523]: data
Out[523]:
   id      Date  Col_1  Col_2  Col_3
0  26  2010-10-18     X    27.50   True
1  42  2010-10-19     Y   -12.50  False
2  63  2010-10-20     Z     5.73   True

In [524]: data.to_sql('data', engine)
```

With some databases, writing large DataFrames can result in errors due to packet size limitations being exceeded. This can be avoided by setting the `chunksize` parameter when calling `to_sql`. For example, the following writes `data` to the database in batches of 1000 rows at a time:

```
In [525]: data.to_sql('data_chunked', engine, chunksize=1000)
```

SQL data types

`to_sql()` will try to map your data to an appropriate SQL data type based on the `dtype` of the data. When you have columns of `dtype object`, pandas will try to infer the data type.

You can always override the default type by specifying the desired SQL type of any of the columns by using the `dtype` argument. This argument needs a dictionary mapping column names to SQLAlchemy types (or strings for the sqlite3 fallback mode). For example, specifying to use the sqlalchemy `String` type instead of the default `Text` type for string columns:

```
In [526]: from sqlalchemy.types import String
In [527]: data.to_sql('data_dtype', engine, dtype={'Col_1': String})
```

Note: Due to the limited support for `timedelta`'s in the different database flavors, columns with type `timedelta64` will be written as integer values as nanoseconds to the database and a warning will be raised.

Note: Columns of `category` `dtype` will be converted to the dense representation as you would get with `np.asarray(categorical)` (e.g. for string categories this gives an array of strings). Because of this, reading the database table back in does **not** generate a `categorical`.

Datetime data types

Using SQLAlchemy, `to_sql()` is capable of writing datetime data that is timezone naive or timezone aware. However, the resulting data stored in the database ultimately depends on the supported data type for datetime data of the database system being used.

The following table lists supported data types for datetime data for some common databases. Other database dialects may have different data types for datetime data.

Database	SQL Datetime Types	Timezone Support
SQLite	TEXT	No
MySQL	TIMESTAMP or DATETIME	No
PostgreSQL	TIMESTAMP or TIMESTAMP WITH TIME ZONE	Yes

When writing timezone aware data to databases that do not support timezones, the data will be written as timezone naive timestamps that are in local time with respect to the timezone.

`read_sql_table()` is also capable of reading datetime data that is timezone aware or naive. When reading `TIMESTAMP WITH TIME ZONE` types, pandas will convert the data to UTC.

Insertion method

New in version 0.24.0.

The parameter `method` controls the SQL insertion clause used. Possible values are:

- None: Uses standard SQL `INSERT` clause (one per row).
- 'multi': Pass multiple values in a single `INSERT` clause. It uses a *special* SQL syntax not supported by all backends. This usually provides better performance for analytic databases like *Presto* and *Redshift*, but has worse performance for traditional SQL backend if the table contains many columns. For more information check the SQLAlchemy documentation.
- callable with signature `(pd_table, conn, keys, data_iter)`: This can be used to implement a more performant insertion method based on specific backend dialect features.

Example of a callable using PostgreSQL `COPY` clause:

```
# Alternative to_sql() *method* for DBs that support COPY FROM
import csv
from io import StringIO

def psql_insert_copy(table, conn, keys, data_iter):
    """
    Execute SQL statement inserting data

    Parameters
    -----
    table : pandas.io.sql.SQLTable
    conn : sqlalchemy.engine.Engine or sqlalchemy.engine.Connection
    keys : list of str
        Column names
    data_iter : Iterable that iterates the values to be inserted
    """
    # gets a DBAPI connection that can provide a cursor
    dbapi_conn = conn.connection
    with dbapi_conn.cursor() as cur:
```

(continues on next page)

(continued from previous page)

```

s_buf = StringIO()
writer = csv.writer(s_buf)
writer.writerows(data_iter)
s_buf.seek(0)

columns = ', '.join('"{}"'.format(k) for k in keys)
if table.schema:
    table_name = '{}.{}'.format(table.schema, table.name)
else:
    table_name = table.name

sql = 'COPY {} ({}) FROM STDIN WITH CSV'.format(
    table_name, columns)
cur.copy_expert(sql=sql, file=s_buf)

```

Reading tables

`read_sql_table()` will read a database table given the table name and optionally a subset of columns to read.

Note: In order to use `read_sql_table()`, you **must** have the SQLAlchemy optional dependency installed.

```

In [528]: pd.read_sql_table('data', engine)
Out[528]:
   index   id      Date  Col_1  Col_2  Col_3
0       0  26  2010-10-18      X  27.50   True
1       1  42  2010-10-19      Y -12.50  False
2       2  63  2010-10-20      Z   5.73   True

```

Note: Note that pandas infers column dtypes from query outputs, and not by looking up data types in the physical database schema. For example, assume `userid` is an integer column in a table. Then, intuitively, `select userid ...` will return integer-valued series, while `select cast(userid as text) ...` will return object-valued (str) series. Accordingly, if the query output is empty, then all resulting columns will be returned as object-valued (since they are most general). If you foresee that your query will sometimes generate an empty result, you may want to explicitly typecast afterwards to ensure dtype integrity.

You can also specify the name of the column as the DataFrame index, and specify a subset of columns to be read.

```

In [529]: pd.read_sql_table('data', engine, index_col='id')
Out[529]:
   index      Date  Col_1  Col_2  Col_3
id
26       0  2010-10-18      X  27.50   True
42       1  2010-10-19      Y -12.50  False
63       2  2010-10-20      Z   5.73   True

In [530]: pd.read_sql_table('data', engine, columns=['Col_1', 'Col_2'])
Out[530]:
   Col_1  Col_2
0      X  27.50
1      Y -12.50
2      Z   5.73

```

And you can explicitly force columns to be parsed as dates:

```
In [531]: pd.read_sql_table('data', engine, parse_dates=['Date'])
Out[531]:
   index  id      Date  Col_1  Col_2  Col_3
0       0  26 2010-10-18      X  27.50   True
1       1  42 2010-10-19      Y -12.50  False
2       2  63 2010-10-20      Z   5.73   True
```

If needed you can explicitly specify a format string, or a dict of arguments to pass to `pandas.to_datetime()`:

```
pd.read_sql_table('data', engine, parse_dates={'Date': '%Y-%m-%d'})
pd.read_sql_table('data', engine,
                  parse_dates={'Date': {'format': '%Y-%m-%d %H:%M:%S'}})
```

You can check if a table exists using `has_table()`

Schema support

Reading from and writing to different schema's is supported through the `schema` keyword in the `read_sql_table()` and `to_sql()` functions. Note however that this depends on the database flavor (sqlite does not have schema's). For example:

```
df.to_sql('table', engine, schema='other_schema')
pd.read_sql_table('table', engine, schema='other_schema')
```

Querying

You can query using raw SQL in the `read_sql_query()` function. In this case you must use the SQL variant appropriate for your database. When using SQLAlchemy, you can also pass SQLAlchemy Expression language constructs, which are database-agnostic.

```
In [532]: pd.read_sql_query('SELECT * FROM data', engine)
Out[532]:
   index  id      Date  Col_1  Col_2  Col_3
0       0  26 2010-10-18 00:00:00.000000      X  27.50   1
1       1  42 2010-10-19 00:00:00.000000      Y -12.50   0
2       2  63 2010-10-20 00:00:00.000000      Z   5.73   1
```

Of course, you can specify a more “complex” query.

```
In [533]: pd.read_sql_query("SELECT id, Col_1, Col_2 FROM data WHERE id = 42;", engine)
Out[533]:
   id  Col_1  Col_2
0   42      Y -12.5
```

The `read_sql_query()` function supports a `chunksize` argument. Specifying this will return an iterator through chunks of the query result:

```
In [534]: df = pd.DataFrame(np.random.randn(20, 3), columns=list('abc'))
In [535]: df.to_sql('data_chunks', engine, index=False)
```

```
In [536]: for chunk in pd.read_sql_query("SELECT * FROM data_chunks",
.....:     engine, chunksize=5):
.....:
.....:     a      b      c
0 -2.963383 -1.438289  1.423986
1  0.610577 -0.940050  1.556614
2 -0.040789  0.896748 -1.244445
3 -0.188847  1.292592 -0.971605
4  1.376572 -1.807231 -2.003675
.....:     a      b      c
0 -0.315078  0.585126 -1.012873
1 -0.916736 -0.823246 -1.061342
2 -0.962767  0.256508  1.032995
3  1.772984  0.395815 -1.524835
4  0.736322  0.967876 -0.788804
.....:     a      b      c
0  0.851514  1.005266  0.140714
1  0.761011  0.327845 -2.900731
2  1.511041  1.545179  0.070821
3 -0.093641  0.014099  0.702961
4  0.870484 -1.521966  0.219802
.....:     a      b      c
0  1.546457 -0.174262  0.831417
1  1.332054  0.438532  0.786117
2 -0.304618  0.956171  0.632107
3 -0.123200  0.579811 -0.617833
4  0.730289 -1.930809 -1.795903
```

You can also run a plain query without creating a DataFrame with `execute()`. This is useful for queries that don't return values, such as `INSERT`. This is functionally equivalent to calling `execute` on the SQLAlchemy engine or db connection object. Again, you must use the SQL syntax variant appropriate for your database.

```
from pandas.io import sql
sql.execute('SELECT * FROM table_name', engine)
sql.execute('INSERT INTO table_name VALUES(?, ?, ?)', engine,
            params=[('id', 1, 12.2, True)])
```

Engine connection examples

To connect with SQLAlchemy you use the `create_engine()` function to create an engine object from database URI. You only need to create the engine once per database you are connecting to.

```
from sqlalchemy import create_engine

engine = create_engine('postgresql://scott:tiger@localhost:5432/mydatabase')

engine = create_engine('mysql+mysqldb://scott:tiger@localhost/foo')

engine = create_engine('oracle://scott:tiger@127.0.0.1:1521/sidname')

engine = create_engine('mssql+pyodbc://mydsn')

# sqlite://<hostname>/<path>
# where <path> is relative:
engine = create_engine('sqlite:///foo.db')
```

(continues on next page)

(continued from previous page)

```
# or absolute, starting with a slash:
engine = create_engine('sqlite:///absolute/path/to/foo.db')
```

For more information see the examples the SQLAlchemy documentation

Advanced SQLAlchemy queries

You can use SQLAlchemy constructs to describe your query.

Use `sqlalchemy.text()` to specify query parameters in a backend-neutral way

```
In [537]: import sqlalchemy as sa

In [538]: pd.read_sql(sa.text('SELECT * FROM data where Col_1=:col1'),
.....:             engine, params={'col1': 'X'})
.....:
Out[538]:
   index    id          Date  Col_1  Col_2  Col_3
0      0  26  2010-10-18  00:00:00.000000      X    27.5      1
```

If you have an SQLAlchemy description of your database you can express where conditions using SQLAlchemy expressions

```
In [539]: metadata = sa.MetaData()

In [540]: data_table = sa.Table('data', metadata,
.....:                     sa.Column('index', sa.Integer),
.....:                     sa.Column('Date', sa.DateTime),
.....:                     sa.Column('Col_1', sa.String),
.....:                     sa.Column('Col_2', sa.Float),
.....:                     sa.Column('Col_3', sa.Boolean),
.....:
.....:

In [541]: pd.read_sql(sa.select([data_table]).where(data_table.c.Col_3 is True),_
engine)
Out[541]:
Empty DataFrame
Columns: [index, Date, Col_1, Col_2, Col_3]
Index: []
```

You can combine SQLAlchemy expressions with parameters passed to `read_sql()` using `sqlalchemy.bindparam()`

```
In [542]: import datetime as dt

In [543]: expr = sa.select([data_table]).where(data_table.c.Date > sa.bindparam('date
'))
In [544]: pd.read_sql(expr, engine, params={'date': dt.datetime(2010, 10, 18)})
Out[544]:
   index      Date  Col_1  Col_2  Col_3
0      1  2010-10-19      Y -12.50  False
1      2  2010-10-20      Z    5.73   True
```

Sqlite fallback

The use of sqlite is supported without using SQLAlchemy. This mode requires a Python database adapter which respect the [Python DB-API](#).

You can create connections like so:

```
import sqlite3
con = sqlite3.connect(':memory:')
```

And then issue the following queries:

```
data.to_sql('data', con)
pd.read_sql_query("SELECT * FROM data", con)
```

3.1.15 Google BigQuery

Warning: Starting in 0.20.0, pandas has split off Google BigQuery support into the separate package `pandas-gbq`. You can pip install `pandas-gbq` to get it.

The `pandas-gbq` package provides functionality to read/write from Google BigQuery.

pandas integrates with this external package. If `pandas-gbq` is installed, you can use the pandas methods `pd.read_gbq` and `DataFrame.to_gbq`, which will call the respective functions from `pandas-gbq`.

Full documentation can be found [here](#).

3.1.16 Stata format

Writing to stata format

The method `to_stata()` will write a DataFrame into a `.dta` file. The format version of this file is always 115 (Stata 12).

```
In [545]: df = pd.DataFrame(np.random.randn(10, 2), columns=list('AB'))
```

```
In [546]: df.to_stata('stata.dta')
```

Stata data files have limited data type support; only strings with 244 or fewer characters, `int8`, `int16`, `int32`, `float32` and `float64` can be stored in `.dta` files. Additionally, *Stata* reserves certain values to represent missing data. Exporting a non-missing value that is outside of the permitted range in *Stata* for a particular data type will retype the variable to the next larger size. For example, `int8` values are restricted to lie between -127 and 127 in *Stata*, and so variables with values above 127 will trigger a conversion to `int16`. `nan` values in floating points data types are stored as the basic missing data type (`.` in *Stata*).

Note: It is not possible to export missing data values for integer data types.

The *Stata* writer gracefully handles other data types including `int64`, `bool`, `uint8`, `uint16`, `uint32` by casting to the smallest supported type that can represent the data. For example, data with a type of `uint8` will be cast to `int8` if all values are less than 127 (the upper bound for non-missing `int8` data in *Stata*), or, if values are outside of this range, the variable is cast to `int16`.

Warning: Conversion from `int64` to `float64` may result in a loss of precision if `int64` values are larger than 2^{**53} .

Warning: `StataWriter` and `to_stata()` only support fixed width strings containing up to 244 characters, a limitation imposed by the version 115 dta file format. Attempting to write *Stata* dta files with strings longer than 244 characters raises a `ValueError`.

Reading from Stata format

The top-level function `read_stata` will read a dta file and return either a `DataFrame` or a `StataReader` that can be used to read the file incrementally.

```
In [547]: pd.read_stata('stata.dta')
Out[547]:
   index      A      B
0      0 -2.012672 -0.884042
1      1 -0.676136  0.809658
2      2  0.727889  1.938622
3      3  0.837410  1.683552
4      4 -1.134942 -0.891729
5      5 -0.605120 -1.654372
6      6 -0.175245  0.643432
7      7  0.332654 -1.208013
8      8 -0.993568  0.028692
9      9  0.139178  0.877023
```

Specifying a `chunksize` yields a `StataReader` instance that can be used to read `chunksize` lines from the file at a time. The `StataReader` object can be used as an iterator.

```
In [548]: reader = pd.read_stata('stata.dta', chunksize=3)

In [549]: for df in reader:
.....:     print(df.shape)
.....:
(3, 3)
(3, 3)
(3, 3)
(1, 3)
```

For more fine-grained control, use `iterator=True` and specify `chunksize` with each call to `read()`.

```
In [550]: reader = pd.read_stata('stata.dta', iterator=True)

In [551]: chunk1 = reader.read(5)

In [552]: chunk2 = reader.read(5)
```

Currently the `index` is retrieved as a column.

The parameter `convert_categoricals` indicates whether value labels should be read and used to create a Categorical variable from them. Value labels can also be retrieved by the function `value_labels`, which requires `read()` to be called before use.

The parameter `convert_missing` indicates whether missing value representations in Stata should be preserved. If `False` (the default), missing values are represented as `np.nan`. If `True`, missing values are represented using `StataMissingValue` objects, and columns containing missing values will have `object` data type.

Note: `read_stata()` and `StataReader` support .dta formats 113-115 (Stata 10-12), 117 (Stata 13), and 118 (Stata 14).

Note: Setting `preserve_dtypes=False` will upcast to the standard pandas data types: `int64` for all integer types and `float64` for floating point data. By default, the Stata data types are preserved when importing.

Categorical data

Categorical data can be exported to *Stata* data files as value labeled data. The exported data consists of the underlying category codes as integer data values and the categories as value labels. *Stata* does not have an explicit equivalent to a `Categorical` and information about *whether* the variable is ordered is lost when exporting.

Warning: *Stata* only supports string value labels, and so `str` is called on the categories when exporting data. Exporting `Categorical` variables with non-string categories produces a warning, and can result a loss of information if the `str` representations of the categories are not unique.

Labeled data can similarly be imported from *Stata* data files as `Categorical` variables using the keyword argument `convert_categoricals` (`True` by default). The keyword argument `order_categoricals` (`True` by default) determines whether imported `Categorical` variables are ordered.

Note: When importing categorical data, the values of the variables in the *Stata* data file are not preserved since `Categorical` variables always use integer data types between `-1` and `n-1` where `n` is the number of categories. If the original values in the *Stata* data file are required, these can be imported by setting `convert_categoricals=False`, which will import original data (but not the variable labels). The original values can be matched to the imported categorical data since there is a simple mapping between the original *Stata* data values and the category codes of imported `Categorical` variables: missing values are assigned code `-1`, and the smallest original value is assigned `0`, the second smallest is assigned `1` and so on until the largest original value is assigned the code `n-1`.

Note: *Stata* supports partially labeled series. These series have value labels for some but not all data values. Importing a partially labeled series will produce a `Categorical` with string categories for the values that are labeled and numeric categories for values with no label.

3.1.17 SAS formats

The top-level function `read_sas()` can read (but not write) SAS *xport* (.XPT) and (since v0.18.0) *SAS7BDAT* (.sas7bdat) format files.

SAS files only contain two value types: ASCII text and floating point values (usually 8 bytes but sometimes truncated). For xport files, there is no automatic type conversion to integers, dates, or categoricals. For SAS7BDAT files, the format codes may allow date variables to be automatically converted to dates. By default the whole file is read and returned as a DataFrame.

Specify a `chunksize` or use `iterator=True` to obtain reader objects (`XportReader` or `SAS7BDATReader`) for incrementally reading the file. The reader objects also have attributes that contain additional information about the file and its variables.

Read a SAS7BDAT file:

```
df = pd.read_sas('sas_data.sas7bdat')
```

Obtain an iterator and read an XPORT file 100,000 lines at a time:

```
def do_something(chunk):
    pass

rdr = pd.read_sas('sas_xport.xpt', chunk=100000)
for chunk in rdr:
    do_something(chunk)
```

The specification for the xport file format is available from the SAS web site.

No official documentation is available for the SAS7BDAT format.

3.1.18 SPSS formats

New in version 0.25.0.

The top-level function `read_spss()` can read (but not write) SPSS *sav* (.sav) and *zsav* (.zsav) format files.

SPSS files contain column names. By default the whole file is read, categorical columns are converted into `pd.Categorical`, and a DataFrame with all columns is returned.

Specify the `usecols` parameter to obtain a subset of columns. Specify `convert_categoricals=False` to avoid converting categorical columns into `pd.Categorical`.

Read an SPSS file:

```
df = pd.read_spss('spss_data.sav')
```

Extract a subset of columns contained in `usecols` from an SPSS file and avoid converting categorical columns into `pd.Categorical`:

```
df = pd.read_spss('spss_data.sav', usecols=['foo', 'bar'],
                  convert_categoricals=False)
```

More information about the *sav* and *zsav* file format is available [here](#).

3.1.19 Other file formats

pandas itself only supports IO with a limited set of file formats that map cleanly to its tabular data model. For reading and writing other file formats into and from pandas, we recommend these packages from the broader community.

netCDF

xarray provides data structures inspired by the pandas DataFrame for working with multi-dimensional datasets, with a focus on the netCDF file format and easy conversion to and from pandas.

3.1.20 Performance considerations

This is an informal comparison of various IO methods, using pandas 0.24.2. Timings are machine dependent and small differences should be ignored.

```
In [1]: sz = 1000000
In [2]: df = pd.DataFrame({'A': np.random.randn(sz), 'B': [1] * sz})

In [3]: df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 1000000 entries, 0 to 999999
Data columns (total 2 columns):
A    1000000 non-null float64
B    1000000 non-null int64
dtypes: float64(1), int64(1)
memory usage: 15.3 MB
```

Given the next test set:

```
import numpy as np

import os

sz = 1000000
df = pd.DataFrame({'A': np.random.randn(sz), 'B': [1] * sz})

sz = 1000000
np.random.seed(42)
df = pd.DataFrame({'A': np.random.randn(sz), 'B': [1] * sz})

def test_sql_write(df):
    if os.path.exists('test.sql'):
        os.remove('test.sql')
    sql_db = sqlite3.connect('test.sql')
    df.to_sql(name='test_table', con=sql_db)
    sql_db.close()

def test_sql_read():
    sql_db = sqlite3.connect('test.sql')
    pd.read_sql_query("select * from test_table", sql_db)
    sql_db.close()

def test_hdf_fixed_write(df):
    df.to_hdf('test_fixed.hdf', 'test', mode='w')
```

(continues on next page)

(continued from previous page)

```

def test_hdf_fixed_read():
    pd.read_hdf('test_fixed.hdf', 'test')

def test_hdf_fixed_write_compress(df):
    df.to_hdf('test_fixed_compress.hdf', 'test', mode='w', complib='blosc')

def test_hdf_fixed_read_compress():
    pd.read_hdf('test_fixed_compress.hdf', 'test')

def test_hdf_table_write(df):
    df.to_hdf('test_table.hdf', 'test', mode='w', format='table')

def test_hdf_table_read():
    pd.read_hdf('test_table.hdf', 'test')

def test_hdf_table_write_compress(df):
    df.to_hdf('test_table_compress.hdf', 'test', mode='w',
              complib='blosc', format='table')

def test_hdf_table_read_compress():
    pd.read_hdf('test_table_compress.hdf', 'test')

def test_csv_write(df):
    df.to_csv('test.csv', mode='w')

def test_csv_read():
    pd.read_csv('test.csv', index_col=0)

def test_feather_write(df):
    df.to_feather('test.feather')

def test_feather_read():
    pd.read_feather('test.feather')

def test_pickle_write(df):
    df.to_pickle('test.pkl')

def test_pickle_read():
    pd.read_pickle('test.pkl')

def test_pickle_write_compress(df):
    df.to_pickle('test.pkl.compress', compression='xz')

def test_pickle_read_compress():
    pd.read_pickle('test.pkl.compress', compression='xz')

def test_parquet_write(df):
    df.to_parquet('test.parquet')

def test_parquet_read():
    pd.read_parquet('test.parquet')

```

When writing, the top-three functions in terms of speed are `test_feather_write`, `test_hdf_fixed_write` and `test_hdf_fixed_write_compress`.

In [4]: %timeit test_sql_write(df)

(continues on next page)

(continued from previous page)

```
3.29 s ± 43.2 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [5]: %timeit test_hdf_fixed_write(df)
19.4 ms ± 560 µs per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [6]: %timeit test_hdf_fixed_write_compress(df)
19.6 ms ± 308 µs per loop (mean ± std. dev. of 7 runs, 10 loops each)

In [7]: %timeit test_hdf_table_write(df)
449 ms ± 5.61 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [8]: %timeit test_hdf_table_write_compress(df)
448 ms ± 11.9 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [9]: %timeit test_csv_write(df)
3.66 s ± 26.2 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [10]: %timeit test_feather_write(df)
9.75 ms ± 117 µs per loop (mean ± std. dev. of 7 runs, 100 loops each)

In [11]: %timeit test_pickle_write(df)
30.1 ms ± 229 µs per loop (mean ± std. dev. of 7 runs, 10 loops each)

In [12]: %timeit test_pickle_write_compress(df)
4.29 s ± 15.9 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [13]: %timeit test_parquet_write(df)
67.6 ms ± 706 µs per loop (mean ± std. dev. of 7 runs, 10 loops each)
```

When reading, the top three are `test_feather_read`, `test_pickle_read` and `test_hdf_fixed_read`.

```
In [14]: %timeit test_sql_read()
1.77 s ± 17.7 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [15]: %timeit test_hdf_fixed_read()
19.4 ms ± 436 µs per loop (mean ± std. dev. of 7 runs, 10 loops each)

In [16]: %timeit test_hdf_fixed_read_compress()
19.5 ms ± 222 µs per loop (mean ± std. dev. of 7 runs, 10 loops each)

In [17]: %timeit test_hdf_table_read()
38.6 ms ± 857 µs per loop (mean ± std. dev. of 7 runs, 10 loops each)

In [18]: %timeit test_hdf_table_read_compress()
38.8 ms ± 1.49 ms per loop (mean ± std. dev. of 7 runs, 10 loops each)

In [19]: %timeit test_csv_read()
452 ms ± 9.04 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [20]: %timeit test_feather_read()
12.4 ms ± 99.7 µs per loop (mean ± std. dev. of 7 runs, 100 loops each)

In [21]: %timeit test_pickle_read()
18.4 ms ± 191 µs per loop (mean ± std. dev. of 7 runs, 100 loops each)

In [22]: %timeit test_pickle_read_compress()
915 ms ± 7.48 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)
```

(continues on next page)

(continued from previous page)

```
In [23]: %timeit test_parquet_read()
24.4 ms ± 146 µs per loop (mean ± std. dev. of 7 runs, 10 loops each)
```

For this test case `test.pkl.compress`, `test.parquet` and `test.feather` took the least space on disk.
Space on disk (in bytes)

3.2 Indexing and selecting data

The axis labeling information in pandas objects serves many purposes:

- Identifies data (i.e. provides *metadata*) using known indicators, important for analysis, visualization, and interactive console display.
- Enables automatic and explicit data alignment.
- Allows intuitive getting and setting of subsets of the data set.

In this section, we will focus on the final point: namely, how to slice, dice, and generally get and set subsets of pandas objects. The primary focus will be on Series and DataFrame as they have received more development attention in this area.

Note: The Python and NumPy indexing operators `[]` and attribute operator `.` provide quick and easy access to pandas data structures across a wide range of use cases. This makes interactive work intuitive, as there's little new to learn if you already know how to deal with Python dictionaries and NumPy arrays. However, since the type of the data to be accessed isn't known in advance, directly using standard operators has some optimization limits. For production code, we recommended that you take advantage of the optimized pandas data access methods exposed in this chapter.

Warning: Whether a copy or a reference is returned for a setting operation, may depend on the context. This is sometimes called `chained assignment` and should be avoided. See [Returning a View versus Copy](#).

See the [MultiIndex / Advanced Indexing](#) for MultiIndex and more advanced indexing documentation.

See the [cookbook](#) for some advanced strategies.

3.2.1 Different choices for indexing

Object selection has had a number of user-requested additions in order to support more explicit location based indexing. Pandas now supports three types of multi-axis indexing.

- `.loc` is primarily label based, but may also be used with a boolean array. `.loc` will raise `KeyError` when the items are not found. Allowed inputs are:
 - A single label, e.g. 5 or 'a' (Note that 5 is interpreted as a *label* of the index. This use is **not** an integer position along the index.).
 - A list or array of labels ['a', 'b', 'c'].
 - A slice object with labels 'a': 'f' (Note that contrary to usual python slices, **both** the start and the stop are included, when present in the index! See [Slicing with labels](#) and [Endpoints are inclusive](#).)
 - A boolean array
 - A callable function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above).

See more at [Selection by Label](#).

- `.iloc` is primarily integer position based (from 0 to `length-1` of the axis), but may also be used with a boolean array. `.iloc` will raise `IndexError` if a requested indexer is out-of-bounds, except `slice` indexers which allow out-of-bounds indexing. (this conforms with Python/NumPy `slice` semantics). Allowed inputs are:
 - An integer e.g. 5.
 - A list or array of integers [4, 3, 0].
 - A slice object with ints 1:7.
 - A boolean array.
 - A callable function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above).

See more at [Selection by Position, Advanced Indexing](#) and [Advanced Hierarchical](#).

- `.loc`, `.iloc`, and also `[]` indexing can accept a `callable` as indexer. See more at [Selection By Callable](#).

Getting values from an object with multi-axes selection uses the following notation (using `.loc` as an example, but the following applies to `.iloc` as well). Any of the axes accessors may be the null slice `:`. Axes left out of the specification are assumed to be `:`, e.g. `p.loc['a']` is equivalent to `p.loc['a', :, :]`.

Object Type	Indexers
Series	<code>s.loc[indexer]</code>
DataFrame	<code>df.loc[row_indexer, column_indexer]</code>

3.2.2 Basics

As mentioned when introducing the data structures in the [last section](#), the primary function of indexing with `[]` (a.k.a. `__getitem__` for those familiar with implementing class behavior in Python) is selecting out lower-dimensional slices. The following table shows return type values when indexing pandas objects with `[]`:

Object Type	Selection	Return Value Type
Series	<code>series[label]</code>	scalar value
DataFrame	<code>frame[colname]</code>	Series corresponding to colname

Here we construct a simple time series data set to use for illustrating the indexing functionality:

```
In [1]: dates = pd.date_range('1/1/2000', periods=8)

In [2]: df = pd.DataFrame(np.random.randn(8, 4),
   ....:                  index=dates, columns=['A', 'B', 'C', 'D'])

In [3]: df
Out[3]:
          A         B         C         D
2000-01-01 -1.157426 -0.096491  0.999344 -1.482012
2000-01-02  0.189291  0.926828 -0.029095  1.776600
2000-01-03 -1.334294  2.085399 -0.633036  0.208208
2000-01-04 -1.723333 -0.355486 -0.143959  0.177635
2000-01-05  1.071746 -0.516876 -0.382709  0.888600
2000-01-06 -0.156260 -0.720254 -0.837161 -0.426902
2000-01-07 -0.354174  0.510804  0.156535  0.294767
2000-01-08 -1.448608 -1.191084 -0.128338 -0.687717
```

Note: None of the indexing functionality is time series specific unless specifically stated.

Thus, as per above, we have the most basic indexing using []:

```
In [4]: s = df['A']

In [5]: s[dates[5]]
Out[5]: -0.15625969875302725
```

You can pass a list of columns to [] to select columns in that order. If a column is not contained in the DataFrame, an exception will be raised. Multiple columns can also be set in this manner:

```
In [6]: df
Out[6]:
          A         B         C         D
2000-01-01 -1.157426 -0.096491  0.999344 -1.482012
2000-01-02  0.189291  0.926828 -0.029095  1.776600
2000-01-03 -1.334294  2.085399 -0.633036  0.208208
2000-01-04 -1.723333 -0.355486 -0.143959  0.177635
2000-01-05  1.071746 -0.516876 -0.382709  0.888600
2000-01-06 -0.156260 -0.720254 -0.837161 -0.426902
2000-01-07 -0.354174  0.510804  0.156535  0.294767
2000-01-08 -1.448608 -1.191084 -0.128338 -0.687717

In [7]: df[['B', 'A']] = df[['A', 'B']]

In [8]: df
Out[8]:
          A         B         C         D
2000-01-01 -0.096491 -1.157426  0.999344 -1.482012
2000-01-02  0.926828  0.189291 -0.029095  1.776600
2000-01-03  2.085399 -1.334294 -0.633036  0.208208
2000-01-04 -0.355486 -1.723333 -0.143959  0.177635
2000-01-05 -0.516876  1.071746 -0.382709  0.888600
2000-01-06 -0.720254 -0.156260 -0.837161 -0.426902
2000-01-07  0.510804 -0.354174  0.156535  0.294767
```

(continues on next page)

(continued from previous page)

```
2000-01-08 -1.191084 -1.448608 -0.128338 -0.687717
```

You may find this useful for applying a transform (in-place) to a subset of the columns.

Warning: pandas aligns all AXES when setting Series and DataFrame from .loc, and .iloc.

This will **not** modify df because the column alignment is before value assignment.

```
In [9]: df[['A', 'B']]  
Out[9]:  
          A            B  
2000-01-01 -0.096491 -1.157426  
2000-01-02  0.926828  0.189291  
2000-01-03  2.085399 -1.334294  
2000-01-04 -0.355486 -1.723333  
2000-01-05 -0.516876  1.071746  
2000-01-06 -0.720254 -0.156260  
2000-01-07  0.510804 -0.354174  
2000-01-08 -1.191084 -1.448608  
  
In [10]: df.loc[:, ['B', 'A']] = df[['A', 'B']]  
  
In [11]: df[['A', 'B']]  
Out[11]:  
          A            B  
2000-01-01 -0.096491 -1.157426  
2000-01-02  0.926828  0.189291  
2000-01-03  2.085399 -1.334294  
2000-01-04 -0.355486 -1.723333  
2000-01-05 -0.516876  1.071746  
2000-01-06 -0.720254 -0.156260  
2000-01-07  0.510804 -0.354174  
2000-01-08 -1.191084 -1.448608
```

The correct way to swap column values is by using raw values:

```
In [12]: df.loc[:, ['B', 'A']] = df[['A', 'B']].to_numpy()  
  
In [13]: df[['A', 'B']]  
Out[13]:  
          A            B  
2000-01-01 -1.157426 -0.096491  
2000-01-02  0.189291  0.926828  
2000-01-03 -1.334294  2.085399  
2000-01-04 -1.723333 -0.355486  
2000-01-05  1.071746 -0.516876  
2000-01-06 -0.156260 -0.720254  
2000-01-07 -0.354174  0.510804  
2000-01-08 -1.448608 -1.191084
```

3.2.3 Attribute access

You may access an index on a Series or column on a DataFrame directly as an attribute:

```
In [14]: sa = pd.Series([1, 2, 3], index=list('abc'))
```

```
In [15]: dfa = df.copy()
```

```
In [16]: sa.b
```

```
Out[16]: 2
```

```
In [17]: dfa.A
```

```
Out[17]:
```

2000-01-01	-1.157426
2000-01-02	0.189291
2000-01-03	-1.334294
2000-01-04	-1.723333
2000-01-05	1.071746
2000-01-06	-0.156260
2000-01-07	-0.354174
2000-01-08	-1.448608

```
Freq: D, Name: A, dtype: float64
```

```
In [18]: sa.a = 5
```

```
In [19]: sa
```

```
Out[19]:
```

a	5
b	2
c	3

```
dtype: int64
```

```
In [20]: dfa.A = list(range(len(dfa.index))) # ok if A already exists
```

```
In [21]: dfa
```

```
Out[21]:
```

	A	B	C	D
2000-01-01	0	-0.096491	0.999344	-1.482012
2000-01-02	1	0.926828	-0.029095	1.776600
2000-01-03	2	2.085399	-0.633036	0.208208
2000-01-04	3	-0.355486	-0.143959	0.177635
2000-01-05	4	-0.516876	-0.382709	0.888600
2000-01-06	5	-0.720254	-0.837161	-0.426902
2000-01-07	6	0.510804	0.156535	0.294767
2000-01-08	7	-1.191084	-0.128338	-0.687717

```
In [22]: dfa['A'] = list(range(len(dfa.index))) # use this form to create a new column
```

```
In [23]: dfa
```

```
Out[23]:
```

	A	B	C	D
2000-01-01	0	-0.096491	0.999344	-1.482012
2000-01-02	1	0.926828	-0.029095	1.776600
2000-01-03	2	2.085399	-0.633036	0.208208
2000-01-04	3	-0.355486	-0.143959	0.177635
2000-01-05	4	-0.516876	-0.382709	0.888600

(continues on next page)

(continued from previous page)

```
2000-01-06 5 -0.720254 -0.837161 -0.426902
2000-01-07 6 0.510804 0.156535 0.294767
2000-01-08 7 -1.191084 -0.128338 -0.687717
```

Warning:

- You can use this access only if the index element is a valid Python identifier, e.g. `s.1` is not allowed. See [here for an explanation of valid identifiers](#).
- The attribute will not be available if it conflicts with an existing method name, e.g. `s.min` is not allowed, but `s['min']` is possible.
- Similarly, the attribute will not be available if it conflicts with any of the following list: `index`, `major_axis`, `minor_axis`, `items`.
- In any of these cases, standard indexing will still work, e.g. `s['1']`, `s['min']`, and `s['index']` will access the corresponding element or column.

If you are using the IPython environment, you may also use tab-completion to see these accessible attributes.

You can also assign a dict to a row of a DataFrame:

```
In [24]: x = pd.DataFrame({'x': [1, 2, 3], 'y': [3, 4, 5]})

In [25]: x.iloc[1] = {'x': 9, 'y': 99}

In [26]: x
Out[26]:
   x    y
0  1    3
1  9   99
2  3    5
```

You can use attribute access to modify an existing element of a Series or column of a DataFrame, but be careful; if you try to use attribute access to create a new column, it creates a new attribute rather than a new column. In 0.21.0 and later, this will raise a UserWarning:

```
In [1]: df = pd.DataFrame({'one': [1., 2., 3.]})
In [2]: df.two = [4, 5, 6]
UserWarning: Pandas doesn't allow Series to be assigned into nonexistent columns -_
↳ see https://pandas.pydata.org/pandas-docs/stable/indexing.html#attribute_access
In [3]: df
Out[3]:
   one
0  1.0
1  2.0
2  3.0
```

3.2.4 Slicing ranges

The most robust and consistent way of slicing ranges along arbitrary axes is described in the [Selection by Position](#) section detailing the `.iloc` method. For now, we explain the semantics of slicing using the `[]` operator.

With Series, the syntax works exactly as with an ndarray, returning a slice of the values and the corresponding labels:

```
In [27]: s[:5]
Out[27]:
2000-01-01    -1.157426
2000-01-02     0.189291
2000-01-03    -1.334294
2000-01-04   -1.723333
2000-01-05    1.071746
Freq: D, Name: A, dtype: float64

In [28]: s[::2]
Out[28]:
2000-01-01    -1.157426
2000-01-03    -1.334294
2000-01-05     1.071746
2000-01-07    -0.354174
Freq: 2D, Name: A, dtype: float64

In [29]: s[::-1]
Out[29]:
2000-01-08    -1.448608
2000-01-07    -0.354174
2000-01-06    -0.156260
2000-01-05     1.071746
2000-01-04   -1.723333
2000-01-03   -1.334294
2000-01-02     0.189291
2000-01-01    -1.157426
Freq: -1D, Name: A, dtype: float64
```

Note that setting works as well:

```
In [30]: s2 = s.copy()

In [31]: s2[:5] = 0

In [32]: s2
Out[32]:
2000-01-01    0.000000
2000-01-02    0.000000
2000-01-03    0.000000
2000-01-04    0.000000
2000-01-05    0.000000
2000-01-06   -0.156260
2000-01-07   -0.354174
2000-01-08   -1.448608
Freq: D, Name: A, dtype: float64
```

With DataFrame, slicing inside of `[]` **slices the rows**. This is provided largely as a convenience since it is such a common operation.

```
In [33]: df[:3]
```

```
Out[33]:
```

	A	B	C	D
2000-01-01	-1.157426	-0.096491	0.999344	-1.482012
2000-01-02	0.189291	0.926828	-0.029095	1.776600
2000-01-03	-1.334294	2.085399	-0.633036	0.208208

```
In [34]: df[::-1]
```

```
Out[34]:
```

	A	B	C	D
2000-01-08	-1.448608	-1.191084	-0.128338	-0.687717
2000-01-07	-0.354174	0.510804	0.156535	0.294767
2000-01-06	-0.156260	-0.720254	-0.837161	-0.426902
2000-01-05	1.071746	-0.516876	-0.382709	0.888600
2000-01-04	-1.723333	-0.355486	-0.143959	0.177635
2000-01-03	-1.334294	2.085399	-0.633036	0.208208
2000-01-02	0.189291	0.926828	-0.029095	1.776600
2000-01-01	-1.157426	-0.096491	0.999344	-1.482012

3.2.5 Selection by label

Warning: Whether a copy or a reference is returned for a setting operation, may depend on the context. This is sometimes called chained assignment and should be avoided. See [Returning a View versus Copy](#).

Warning:

.loc is strict when you present slicers that are not compatible (or convertible) with the index type.
For example using integers in a DatetimeIndex. These will raise a TypeError.

```
In [35]: dfl = pd.DataFrame(np.random.randn(5, 4),
....:                         columns=list('ABCD'),
....:                         index=pd.date_range('20130101', periods=5))
```

```
In [36]: dfl
```

```
Out[36]:
```

	A	B	C	D
2013-01-01	-2.100928	1.025928	-0.007973	-1.336035
2013-01-02	0.915382	-0.130655	0.022627	-1.425459
2013-01-03	0.271939	0.169543	0.692513	-1.231139
2013-01-04	1.692870	0.783855	-0.721626	1.698994
2013-01-05	-0.349882	1.586451	1.454199	0.149458

```
In [4]: dfl.loc[2:3]
```

TypeError: cannot do slice indexing on <class 'pandas.tseries.index.DatetimeIndex'>
with these indexers [2] of <type 'int'>

String likes in slicing can be convertible to the type of the index and lead to natural slicing.

```
In [37]: dfl.loc['20130102':'20130104']
```

```
Out[37]:
```

	A	B	C	D
2013-01-02	0.915382	-0.130655	0.022627	-1.425459
2013-01-03	0.271939	0.169543	0.692513	-1.231139
2013-01-04	1.692870	0.783855	-0.721626	1.698994

Warning: Starting in 0.21.0, pandas will show a `FutureWarning` if indexing with a list with missing labels. In the future this will raise a `KeyError`. See [list-like Using loc with missing keys in a list is Deprecated](#).

pandas provides a suite of methods in order to have **purely label based indexing**. This is a strict inclusion based protocol. Every label asked for must be in the index, or a `KeyError` will be raised. When slicing, both the start bound **AND** the stop bound are *included*, if present in the index. Integers are valid labels, but they refer to the label **and not the position**.

The `.loc` attribute is the primary access method. The following are valid inputs:

- A single label, e.g. 5 or 'a' (Note that 5 is interpreted as a *label* of the index. This use is **not** an integer position along the index.).
- A list or array of labels ['a', 'b', 'c'].
- A slice object with labels 'a':'f' (Note that contrary to usual python slices, **both** the start and the stop are included, when present in the index! See [Slicing with labels](#)).
- A boolean array.
- A callable, see [Selection By Callable](#).

```
In [38]: s1 = pd.Series(np.random.randn(6), index=list('abcdef'))
```

```
In [39]: s1
```

```
Out[39]:
```

```
a    1.018393
b   -0.565651
c   -1.590951
d   -0.651777
e    0.456407
f    1.134054
dtype: float64
```

```
In [40]: s1.loc['c':]
```

```
Out[40]:
```

```
c   -1.590951
d   -0.651777
e    0.456407
f    1.134054
dtype: float64
```

```
In [41]: s1.loc['b']
```

```
Out[41]: -0.5656513106035832
```

Note that setting works as well:

```
In [42]: s1.loc['c'] = 0
```

```
In [43]: s1
```

```
Out[43]:
```

```
a    1.018393
b   -0.565651
c    0.000000
d    0.000000
```

(continues on next page)

(continued from previous page)

```
e    0.000000  
f    0.000000  
dtype: float64
```

With a DataFrame:

```
In [44]: df1 = pd.DataFrame(np.random.randn(6, 4),  
.....:                      index=list('abcdef'),  
.....:                      columns=list('ABCD'))  
.....:  
  
In [45]: df1  
Out[45]:  
          A         B         C         D  
a  1.695493  1.632303 -1.726092  0.486227  
b -0.625187  0.386616 -0.048112 -2.598355  
c -0.871135 -0.209156  0.004590  0.449006  
d  0.573428  0.697186 -2.442512 -1.423556  
e -0.304997  0.672794  0.954090  1.323584  
f  0.015720 -0.815293  0.164562  0.576599  
  
In [46]: df1.loc[['a', 'b', 'd'], :]  
Out[46]:  
          A         B         C         D  
a  1.695493  1.632303 -1.726092  0.486227  
b -0.625187  0.386616 -0.048112 -2.598355  
d  0.573428  0.697186 -2.442512 -1.423556
```

Accessing via label slices:

```
In [47]: df1.loc['d':, 'A':'C']  
Out[47]:  
          A         B         C  
d  0.573428  0.697186 -2.442512  
e -0.304997  0.672794  0.954090  
f  0.015720 -0.815293  0.164562
```

For getting a cross section using a label (equivalent to `df.xs('a')`):

```
In [48]: df1.loc['a']  
Out[48]:  
A    1.695493  
B    1.632303  
C   -1.726092  
D    0.486227  
Name: a, dtype: float64
```

For getting values with a boolean array:

```
In [49]: df1.loc['a'] > 0  
Out[49]:  
A    True  
B    True  
C   False  
D    True  
Name: a, dtype: bool
```

(continues on next page)

(continued from previous page)

```
In [50]: df1.loc[:, df1.loc['a'] > 0]
Out[50]:
```

	A	B	D
a	1.695493	1.632303	0.486227
b	-0.625187	0.386616	-2.598355
c	-0.871135	-0.209156	0.449006
d	0.573428	0.697186	-1.423556
e	-0.304997	0.672794	1.323584
f	0.015720	-0.815293	0.576599

For getting a value explicitly:

```
# this is also equivalent to ``df1.at['a', 'A']``
In [51]: df1.loc['a', 'A']
Out[51]: 1.6954931738440173
```

Slicing with labels

When using `.loc` with slices, if both the start and the stop labels are present in the index, then elements *located* between the two (including them) are returned:

```
In [52]: s = pd.Series(list('abcde'), index=[0, 3, 2, 5, 4])

In [53]: s.loc[3:5]
Out[53]:
```

3	b
2	c
5	d

dtype: object

If at least one of the two is absent, but the index is sorted, and can be compared against start and stop labels, then slicing will still work as expected, by selecting labels which *rank* between the two:

```
In [54]: s.sort_index()
Out[54]:
```

0	a
2	c
3	b
4	e
5	d

dtype: object

```
In [55]: s.sort_index().loc[1:6]
Out[55]:
```

2	c
3	b
4	e
5	d

dtype: object

However, if at least one of the two is absent *and* the index is not sorted, an error will be raised (since doing otherwise would be computationally expensive, as well as potentially ambiguous for mixed type indexes). For instance, in the above example, `s.loc[1:6]` would raise `KeyError`.

For the rationale behind this behavior, see [Endpoints are inclusive](#).

3.2.6 Selection by position

Warning: Whether a copy or a reference is returned for a setting operation, may depend on the context. This is sometimes called `chained assignment` and should be avoided. See [Returning a View versus Copy](#).

Pandas provides a suite of methods in order to get **purely integer based indexing**. The semantics follow closely Python and NumPy slicing. These are 0-based indexing. When slicing, the start bound is *included*, while the upper bound is *excluded*. Trying to use a non-integer, even a **valid** label will raise an `IndexError`.

The `.iloc` attribute is the primary access method. The following are valid inputs:

- An integer e.g. 5.
- A list or array of integers [4, 3, 0].
- A slice object with ints 1:7.
- A boolean array.
- A callable, see [Selection By Callable](#).

```
In [56]: s1 = pd.Series(np.random.randn(5), index=list(range(0, 10, 2)))

In [57]: s1
Out[57]:
0    -0.813837
2     1.020094
4    -0.538755
6    -0.273898
8     1.374350
dtype: float64

In [58]: s1.iloc[:3]
Out[58]:
0    -0.813837
2     1.020094
4    -0.538755
dtype: float64

In [59]: s1.iloc[3]
Out[59]: -0.2738980637291465
```

Note that setting works as well:

```
In [60]: s1.iloc[:3] = 0

In [61]: s1
Out[61]:
0    0.000000
2    0.000000
4    0.000000
6   -0.273898
8    1.374350
dtype: float64
```

With a DataFrame:

```
In [62]: df1 = pd.DataFrame(np.random.randn(6, 4),
....:                         index=list(range(0, 12, 2)),
....:                         columns=list(range(0, 8, 2)))
....:

In [63]: df1
Out[63]:
      0      2      4      6
0 -0.769208 -0.094955 -0.339642  1.131238
2 -1.165074  0.191823 -0.424832  0.641310
4 -1.389117  0.367491  2.164790  1.126079
6  1.550817  0.826973 -0.677486  2.087563
8  0.117134 -0.855723  0.082120  1.276149
10 0.270969  1.210188 -0.988631 -1.253327
```

Select via integer slicing:

```
In [64]: df1.iloc[:3]
Out[64]:
      0      2      4      6
0 -0.769208 -0.094955 -0.339642  1.131238
2 -1.165074  0.191823 -0.424832  0.641310
4 -1.389117  0.367491  2.164790  1.126079

In [65]: df1.iloc[1:5, 2:4]
Out[65]:
      4      6
2 -0.424832  0.641310
4  2.164790  1.126079
6 -0.677486  2.087563
8  0.082120  1.276149
```

Select via integer list:

```
In [66]: df1.iloc[[1, 3, 5], [1, 3]]
Out[66]:
      2      6
2  0.191823  0.641310
6  0.826973  2.087563
10 1.210188 -1.253327
```

```
In [67]: df1.iloc[1:3, :]
Out[67]:
      0      2      4      6
2 -1.165074  0.191823 -0.424832  0.641310
4 -1.389117  0.367491  2.164790  1.126079
```

```
In [68]: df1.iloc[:, 1:3]
Out[68]:
      2      4
0 -0.094955 -0.339642
2  0.191823 -0.424832
4  0.367491  2.164790
6  0.826973 -0.677486
8 -0.855723  0.082120
10 1.210188 -0.988631
```

```
# this is also equivalent to ``df1.iat[1,1]``
In [69]: df1.iloc[1, 1]
Out[69]: 0.1918230563556888
```

For getting a cross section using an integer position (equiv to `df.xs(1)`):

```
In [70]: df1.iloc[1]
Out[70]:
0    -1.165074
2     0.191823
4    -0.424832
6     0.641310
Name: 2, dtype: float64
```

Out of range slice indexes are handled gracefully just as in Python/Numpy.

```
# these are allowed in python/numpy.
In [71]: x = list('abcdef')

In [72]: x
Out[72]: ['a', 'b', 'c', 'd', 'e', 'f']

In [73]: x[4:10]
Out[73]: ['e', 'f']

In [74]: x[8:10]
Out[74]: []

In [75]: s = pd.Series(x)

In [76]: s
Out[76]:
0    a
1    b
2    c
3    d
4    e
5    f
dtype: object

In [77]: s.iloc[4:10]
Out[77]:
4    e
5    f
dtype: object

In [78]: s.iloc[8:10]
Out[78]: Series([], dtype: object)
```

Note that using slices that go out of bounds can result in an empty axis (e.g. an empty DataFrame being returned).

```
In [79]: df1 = pd.DataFrame(np.random.randn(5, 2), columns=list('AB'))
In [80]: df1
Out[80]:
       A          B
0 -1.141824  0.487982
```

(continues on next page)

(continued from previous page)

```

1 1.110710 1.775785
2 -0.158929 1.256688
3 0.480722 0.545781
4 -1.214729 0.259405

In [81]: df1.iloc[:, 2:3]
Out[81]:
Empty DataFrame
Columns: []
Index: [0, 1, 2, 3, 4]

In [82]: df1.iloc[:, 1:3]
Out[82]:
          B
0  0.487982
1  1.775785
2  1.256688
3  0.545781
4  0.259405

In [83]: df1.iloc[4:6]
Out[83]:
      A         B
4 -1.214729  0.259405

```

A single indexer that is out of bounds will raise an `IndexError`. A list of indexers where any element is out of bounds will raise an `IndexError`.

```

>>> df1.iloc[[4, 5, 6]]
IndexError: positional indexers are out-of-bounds

>>> df1.iloc[:, 4]
IndexError: single positional indexer is out-of-bounds

```

3.2.7 Selection by callable

`.loc`, `.iloc`, and also `[]` indexing can accept a callable as indexer. The callable must be a function with one argument (the calling Series or DataFrame) that returns valid output for indexing.

```

In [84]: df1 = pd.DataFrame(np.random.randn(6, 4),
.....:                         index=list('abcdef'),
.....:                         columns=list('ABCD'))
.....:

In [85]: df1
Out[85]:
          A         B         C         D
a -1.898204  0.933280  0.410757 -1.209116
b  1.072207 -2.076376 -0.032087 -1.179905
c  0.819041  0.169362  0.395066  1.793339
d  0.620358  0.687095  0.924752 -0.953211
e  0.272744 -0.264613 -0.299304  0.828769
f  1.384847  1.408420 -0.599304  1.455457

In [86]: df1.loc[lambda df: df['A'] > 0, :]

```

(continues on next page)

(continued from previous page)

Out[86]:

	A	B	C	D
b	1.072207	-2.076376	-0.032087	-1.179905
c	0.819041	0.169362	0.395066	1.793339
d	0.620358	0.687095	0.924752	-0.953211
e	0.272744	-0.264613	-0.299304	0.828769
f	1.384847	1.408420	-0.599304	1.455457

In [87]: df1.loc[:, lambda df: ['A', 'B']]**Out[87]:**

	A	B
a	-1.898204	0.933280
b	1.072207	-2.076376
c	0.819041	0.169362
d	0.620358	0.687095
e	0.272744	-0.264613
f	1.384847	1.408420

In [88]: df1.iloc[:, lambda df: [0, 1]]**Out[88]:**

	A	B
a	-1.898204	0.933280
b	1.072207	-2.076376
c	0.819041	0.169362
d	0.620358	0.687095
e	0.272744	-0.264613
f	1.384847	1.408420

In [89]: df1[lambda df: df.columns[0]]**Out[89]:**

	A
a	-1.898204
b	1.072207
c	0.819041
d	0.620358
e	0.272744
f	1.384847

Name: A, dtype: float64

You can use callable indexing in Series.

In [90]: df1['A'].loc[lambda s: s > 0]**Out[90]:**

	A
b	1.072207
c	0.819041
d	0.620358
e	0.272744
f	1.384847

Name: A, dtype: float64

Using these methods / indexers, you can chain data selection operations without using a temporary variable.

In [91]: bb = pd.read_csv('data/baseball.csv', index_col='id')

```
In [92]: (bb.groupby(['year', 'team']).sum()
      ....: .loc[lambda df: df['r'] > 100])
      ....:
```

Out[92]:

(continues on next page)

3.2.8 IX indexer is deprecated

Warning: Starting in 0.20.0, the `.ix` indexer is deprecated, in favor of the more strict `.iloc` and `.loc` indexers.

`.ix` offers a lot of magic on the inference of what the user wants to do. To wit, `.ix` can decide to index *positionally* OR via *labels* depending on the data type of the index. This has caused quite a bit of user confusion over the years.

The recommended methods of indexing are:

- `.loc` if you want to *label* index.
- `.iloc` if you want to *positionally* index.

```
In [93]: dfd = pd.DataFrame({'A': [1, 2, 3],
.....:                  'B': [4, 5, 6]},
.....:                 index=list('abc'))
.....:
```

```
In [94]: dfd
Out[94]:
   A   B
a  1  4
b  2  5
c  3  6
```

Previous behavior, where you wish to get the 0th and the 2nd elements from the index in the ‘A’ column.

```
In [3]: dfd.ix[[0, 2], 'A']
Out[3]:
a    1
c    3
Name: A, dtype: int64
```

Using `.loc`. Here we will select the appropriate indexes from the index, then use *label* indexing.

```
In [95]: dfd.loc[dfd.index[[0, 2]], 'A']
Out[95]:
a    1
c    3
Name: A, dtype: int64
```

This can also be expressed using `.iloc`, by explicitly getting locations on the indexers, and using *positional* indexing to select things.

```
In [96]: dfd.iloc[[0, 2], dfd.columns.get_loc('A')]
Out[96]:
a    1
c    3
Name: A, dtype: int64
```

For getting *multiple* indexers, using `.get_indexer`:

```
In [97]: dfd.iloc[[0, 2], dfd.columns.get_indexer(['A', 'B'])]
Out[97]:
   A   B
a  1  4
c  3  6
```

3.2.9 Indexing with list with missing labels is deprecated

Warning: Starting in 0.21.0, using `.loc` or `[]` with a list with one or more missing labels, is deprecated, in favor of `.reindex`.

In prior versions, using `.loc[list-of-labels]` would work as long as *at least 1* of the keys was found (otherwise it would raise a `KeyError`). This behavior is deprecated and will show a warning message pointing to this section. The recommended alternative is to use `.reindex()`.

For example.

```
In [98]: s = pd.Series([1, 2, 3])
In [99]: s
Out[99]:
0    1
1    2
2    3
dtype: int64
```

Selection with all keys found is unchanged.

```
In [100]: s.loc[[1, 2]]
Out[100]:
1    2
2    3
dtype: int64
```

Previous behavior

```
In [4]: s.loc[[1, 2, 3]]
Out[4]:
1    2.0
2    3.0
3    NaN
dtype: float64
```

Current behavior

```
In [4]: s.loc[[1, 2, 3]]
Passing list-likes to .loc with any non-matching elements will raise
KeyError in the future, you can use .reindex() as an alternative.

See the documentation here:
https://pandas.pydata.org/pandas-docs/stable/indexing.html#deprecate-loc-reindex-
↪listlike

Out[4]:
1    2.0
2    3.0
3    NaN
dtype: float64
```

Reindexing

The idiomatic way to achieve selecting potentially not-found elements is via `.reindex()`. See also the section on [reindexing](#).

```
In [101]: s.reindex([1, 2, 3])
Out[101]:
1    2.0
2    3.0
3    NaN
dtype: float64
```

Alternatively, if you want to select only *valid* keys, the following is idiomatic and efficient; it is guaranteed to preserve the `dtype` of the selection.

```
In [102]: labels = [1, 2, 3]

In [103]: s.loc[s.index.intersection(labels)]
Out[103]:
1    2
2    3
dtype: int64
```

Having a duplicated index will raise for a `.reindex()`:

```
In [104]: s = pd.Series(np.arange(4), index=['a', 'a', 'b', 'c'])
In [105]: labels = ['c', 'd']
```

```
In [17]: s.reindex(labels)
ValueError: cannot reindex from a duplicate axis
```

Generally, you can intersect the desired labels with the current axis, and then reindex.

```
In [106]: s.loc[s.index.intersection(labels)].reindex(labels)
Out[106]:
c    3.0
d    NaN
dtype: float64
```

However, this would *still* raise if your resulting index is duplicated.

```
In [41]: labels = ['a', 'd']

In [42]: s.loc[s.index.intersection(labels)].reindex(labels)
ValueError: cannot reindex from a duplicate axis
```

3.2.10 Selecting random samples

A random selection of rows or columns from a Series or DataFrame with the `sample()` method. The method will sample rows by default, and accepts a specific number of rows/columns to return, or a fraction of rows.

```
In [107]: s = pd.Series([0, 1, 2, 3, 4, 5])

# When no arguments are passed, returns 1 row.
In [108]: s.sample()
Out[108]:
0    0
dtype: int64

# One may specify either a number of rows:
In [109]: s.sample(n=3)
Out[109]:
2    2
1    1
5    5
dtype: int64

# Or a fraction of the rows:
In [110]: s.sample(frac=0.5)
Out[110]:
0    0
2    2
3    3
dtype: int64
```

By default, `sample` will return each row at most once, but one can also sample with replacement using the `replace` option:

```
In [111]: s = pd.Series([0, 1, 2, 3, 4, 5])

# Without replacement (default):
In [112]: s.sample(n=6, replace=False)
Out[112]:
3    3
2    2
4    4
0    0
5    5
```

(continues on next page)

(continued from previous page)

```

1    1
dtype: int64

# With replacement:
In [113]: s.sample(n=6, replace=True)
Out[113]:
0    0
2    2
0    0
3    3
1    1
2    2
dtype: int64

```

By default, each row has an equal probability of being selected, but if you want rows to have different probabilities, you can pass the `sample` function sampling weights as `weights`. These weights can be a list, a NumPy array, or a Series, but they must be of the same length as the object you are sampling. Missing values will be treated as a weight of zero, and inf values are not allowed. If weights do not sum to 1, they will be re-normalized by dividing all weights by the sum of the weights. For example:

```

In [114]: s = pd.Series([0, 1, 2, 3, 4, 5])

In [115]: example_weights = [0, 0, 0.2, 0.2, 0.2, 0.4]

In [116]: s.sample(n=3, weights=example_weights)
Out[116]:
5    5
4    4
3    3
dtype: int64

# Weights will be re-normalized automatically
In [117]: example_weights2 = [0.5, 0, 0, 0, 0, 0]

In [118]: s.sample(n=1, weights=example_weights2)
Out[118]:
0    0
dtype: int64

```

When applied to a DataFrame, you can use a column of the DataFrame as sampling weights (provided you are sampling rows and not columns) by simply passing the name of the column as a string.

```

In [119]: df2 = pd.DataFrame({'col1': [9, 8, 7, 6],
                           'weight_column': [0.5, 0.4, 0.1, 0]})

In [120]: df2.sample(n=3, weights='weight_column')
Out[120]:
   col1  weight_column
0      9          0.5
2      7          0.1
1      8          0.4

```

`sample` also allows users to sample columns instead of rows using the `axis` argument.

```
In [121]: df3 = pd.DataFrame({'col1': [1, 2, 3], 'col2': [2, 3, 4]})
```

(continues on next page)

(continued from previous page)

```
In [122]: df3.sample(n=1, axis=1)
Out[122]:
   col1
0      1
1      2
2      3
```

Finally, one can also set a seed for `sample`'s random number generator using the `random_state` argument, which will accept either an integer (as a seed) or a NumPy RandomState object.

```
In [123]: df4 = pd.DataFrame({'col1': [1, 2, 3], 'col2': [2, 3, 4]})

# With a given seed, the sample will always draw the same rows.
In [124]: df4.sample(n=2, random_state=2)
Out[124]:
   col1  col2
2      3      4
1      2      3

In [125]: df4.sample(n=2, random_state=2)
Out[125]:
   col1  col2
2      3      4
1      2      3
```

3.2.11 Setting with enlargement

The `.loc/[]` operations can perform enlargement when setting a non-existent key for that axis.

In the Series case this is effectively an appending operation.

```
In [126]: se = pd.Series([1, 2, 3])

In [127]: se
Out[127]:
0    1
1    2
2    3
dtype: int64

In [128]: se[5] = 5.

In [129]: se
Out[129]:
0    1.0
1    2.0
2    3.0
5    5.0
dtype: float64
```

A DataFrame can be enlarged on either axis via `.loc`.

```
In [130]: dfi = pd.DataFrame(np.arange(6).reshape(3, 2),
.....:           columns=['A', 'B'])
```

(continues on next page)

(continued from previous page)

```
....:

In [131]: dfi
Out[131]:
   A   B
0  0  1
1  2  3
2  4  5

In [132]: dfi.loc[:, 'C'] = dfi.loc[:, 'A']

In [133]: dfi
Out[133]:
   A   B   C
0  0  1  0
1  2  3  2
2  4  5  4
```

This is like an append operation on the DataFrame.

```
In [134]: dfi.loc[3] = 5

In [135]: dfi
Out[135]:
   A   B   C
0  0  1  0
1  2  3  2
2  4  5  4
3  5  5  5
```

3.2.12 Fast scalar value getting and setting

Since indexing with [] must handle a lot of cases (single-label access, slicing, boolean indexing, etc.), it has a bit of overhead in order to figure out what you're asking for. If you only want to access a scalar value, the fastest way is to use the `at` and `iat` methods, which are implemented on all of the data structures.

Similarly to `loc`, `at` provides **label** based scalar lookups, while, `iat` provides **integer** based lookups analogously to `iloc`

```
In [136]: s.iat[5]
Out[136]: 5

In [137]: df.at[dates[5], 'A']
Out[137]: -0.15625969875302725

In [138]: df.iat[3, 0]
Out[138]: -1.7233332966009836
```

You can also set using these same indexers.

```
In [139]: df.at[dates[5], 'E'] = 7
In [140]: df.iat[3, 0] = 7
```

`at` may enlarge the object in-place as above if the indexer is missing.

```
In [141]: df.at[dates[-1] + pd.Timedelta('1 day'), 0] = 7
```

```
In [142]: df
```

```
Out[142]:
```

	A	B	C	D	E	0
2000-01-01	-1.157426	-0.096491	0.999344	-1.482012	NaN	NaN
2000-01-02	0.189291	0.926828	-0.029095	1.776600	NaN	NaN
2000-01-03	-1.334294	2.085399	-0.633036	0.208208	NaN	NaN
2000-01-04	7.000000	-0.355486	-0.143959	0.177635	NaN	NaN
2000-01-05	1.071746	-0.516876	-0.382709	0.888600	NaN	NaN
2000-01-06	-0.156260	-0.720254	-0.837161	-0.426902	7.0	NaN
2000-01-07	-0.354174	0.510804	0.156535	0.294767	NaN	NaN
2000-01-08	-1.448608	-1.191084	-0.128338	-0.687717	NaN	NaN
2000-01-09	NaN	NaN	NaN	NaN	NaN	7.0

3.2.13 Boolean indexing

Another common operation is the use of boolean vectors to filter the data. The operators are: `|` for `or`, `&` for `and`, and `~` for `not`. These **must** be grouped by using parentheses, since by default Python will evaluate an expression such as `df['A'] > 2 & df['B'] < 3` as `df['A'] > (2 & df['B']) < 3`, while the desired evaluation order is `(df['A'] > 2) & (df['B'] < 3)`.

Using a boolean vector to index a Series works exactly as in a NumPy ndarray:

```
In [143]: s = pd.Series(range(-3, 4))
```

```
In [144]: s
```

```
Out[144]:
```

```
0    -3  
1    -2  
2    -1  
3     0  
4     1  
5     2  
6     3  
dtype: int64
```

```
In [145]: s[s > 0]
```

```
Out[145]:
```

```
4     1  
5     2  
6     3  
dtype: int64
```

```
In [146]: s[(s < -1) | (s > 0.5)]
```

```
Out[146]:
```

```
0    -3  
1    -2  
4     1  
5     2  
6     3  
dtype: int64
```

```
In [147]: s[~(s < 0)]
```

```
Out[147]:
```

```
3     0
```

(continues on next page)

(continued from previous page)

```
4    1
5    2
6    3
dtype: int64
```

You may select rows from a DataFrame using a boolean vector the same length as the DataFrame's index (for example, something derived from one of the columns of the DataFrame):

```
In [148]: df[df['A'] > 0]
Out[148]:
          A         B         C         D         E      0
2000-01-02  0.189291  0.926828 -0.029095  1.776600  NaN  NaN
2000-01-04  7.000000 -0.355486 -0.143959  0.177635  NaN  NaN
2000-01-05  1.071746 -0.516876 -0.382709  0.888600  NaN  NaN
```

List comprehensions and the `map` method of Series can also be used to produce more complex criteria:

```
In [149]: df2 = pd.DataFrame({'a': ['one', 'one', 'two', 'three', 'two', 'one', 'six
   ..'],
   ....:                 'b': ['x', 'y', 'y', 'x', 'y', 'x', 'x'],
   ....:                 'c': np.random.randn(7)})

# only want 'two' or 'three'
In [150]: criterion = df2['a'].map(lambda x: x.startswith('t'))
```

```
In [151]: df2[criterion]
Out[151]:
       a     b     c
2    two   y  0.344065
3  three  x  1.275247
4    two   y  1.303763

# equivalent but slower
In [152]: df2[[x.startswith('t') for x in df2['a']]]
Out[152]:
       a     b     c
2    two   y  0.344065
3  three  x  1.275247
4    two   y  1.303763

# Multiple criteria
In [153]: df2[criterion & (df2['b'] == 'x')]
Out[153]:
       a     b     c
3  three  x  1.275247
```

With the choice methods `Selection by Label`, `Selection by Position`, and `Advanced Indexing` you may select along more than one axis using boolean vectors combined with other indexing expressions.

```
In [154]: df2.loc[criterion & (df2['b'] == 'x'), 'b':'c']
Out[154]:
       b     c
3    x  1.275247
```

3.2.14 Indexing with `isin`

Consider the `isin()` method of `Series`, which returns a boolean vector that is true wherever the `Series` elements exist in the passed list. This allows you to select rows where one or more columns have values you want:

```
In [155]: s = pd.Series(np.arange(5), index=np.arange(5) [::-1], dtype='int64')

In [156]: s
Out[156]:
4      0
3      1
2      2
1      3
0      4
dtype: int64

In [157]: s.isin([2, 4, 6])
Out[157]:
4    False
3    False
2     True
1    False
0     True
dtype: bool

In [158]: s[s.isin([2, 4, 6])]
Out[158]:
2      2
0      4
dtype: int64
```

The same method is available for `Index` objects and is useful for the cases when you don't know which of the sought labels are in fact present:

```
In [159]: s[s.index.isin([2, 4, 6])]
Out[159]:
4      0
2      2
dtype: int64

# compare it to the following
In [160]: s.reindex([2, 4, 6])
Out[160]:
2    2.0
4    0.0
6    NaN
dtype: float64
```

In addition to that, `MultiIndex` allows selecting a separate level to use in the membership check:

```
In [161]: s_mi = pd.Series(np.arange(6),
.....:                               index=pd.MultiIndex.from_product([[0, 1], ['a', 'b', 'c'],
.....:                                         ['']]))
.....:

In [162]: s_mi
Out[162]:
0  a  0
```

(continues on next page)

(continued from previous page)

```

b    1
c    2
1  a    3
   b    4
   c    5
dtype: int64

In [163]: s_mi.iloc[s_mi.index.isin([(1, 'a'), (2, 'b'), (0, 'c')])]
Out[163]:
0  c    2
1  a    3
dtype: int64

In [164]: s_mi.iloc[s_mi.index.isin(['a', 'c', 'e'], level=1)]
Out[164]:
0  a    0
   c    2
1  a    3
   c    5
dtype: int64

```

DataFrame also has an `isin()` method. When calling `isin`, pass a set of values as either an array or dict. If values is an array, `isin` returns a DataFrame of booleans that is the same shape as the original DataFrame, with True wherever the element is in the sequence of values.

```

In [165]: df = pd.DataFrame({'vals': [1, 2, 3, 4], 'ids': ['a', 'b', 'f', 'n'],
.....:                      'ids2': ['a', 'n', 'c', 'n']})
.....:

In [166]: values = ['a', 'b', 1, 3]

In [167]: df.isin(values)
Out[167]:
  vals    ids  ids2
0  True    True   True
1 False    True  False
2  True   False  False
3 False   False  False

```

Oftentimes you'll want to match certain values with certain columns. Just make values a dict where the key is the column, and the value is a list of items you want to check for.

```

In [168]: values = {'ids': ['a', 'b'], 'vals': [1, 3]}

In [169]: df.isin(values)
Out[169]:
  vals    ids  ids2
0  True    True  False
1 False   True  False
2  True   False  False
3 False   False  False

```

Combine DataFrame's `isin` with the `any()` and `all()` methods to quickly select subsets of your data that meet a given criteria. To select a row where each column meets its own criterion:

```
In [170]: values = {'ids': ['a', 'b'], 'ids2': ['a', 'c'], 'vals': [1, 3]}
```

(continues on next page)

(continued from previous page)

```
In [171]: row_mask = df.isin(values).all(1)
```

```
In [172]: df[row_mask]
```

```
Out[172]:
```

	vals	ids	ids2
0	1	a	a

3.2.15 The `where()` Method and Masking

Selecting values from a Series with a boolean vector generally returns a subset of the data. To guarantee that selection output has the same shape as the original data, you can use the `where` method in Series and DataFrame.

To return only the selected rows:

```
In [173]: s[s > 0]
```

```
Out[173]:
```

3	1
2	2
1	3
0	4

```
dtype: int64
```

To return a Series of the same shape as the original:

```
In [174]: s.where(s > 0)
```

```
Out[174]:
```

4	NaN
3	1.0
2	2.0
1	3.0
0	4.0

```
dtype: float64
```

Selecting values from a DataFrame with a boolean criterion now also preserves input data shape. `where` is used under the hood as the implementation. The code below is equivalent to `df.where(df < 0)`.

```
In [175]: df[df < 0]
```

```
Out[175]:
```

	A	B	C	D
2000-01-01	-0.986205	-1.719758	-2.230079	-0.439106
2000-01-02	-2.397242	NaN	NaN	-0.237058
2000-01-03	-1.482014	NaN	-0.782186	NaN
2000-01-04	-0.480306	-1.051903	-0.987736	-0.182060
2000-01-05	-0.379467	NaN	-0.138556	NaN
2000-01-06	-0.514897	-0.117796	-0.108906	-1.142649
2000-01-07	-1.349120	NaN	-0.128845	-1.352644
2000-01-08	NaN	NaN	NaN	-1.495080

In addition, `where` takes an optional `other` argument for replacement of values where the condition is False, in the returned copy.

```
In [176]: df.where(df < 0, -df)
```

```
Out[176]:
```

	A	B	C	D
--	---	---	---	---

(continues on next page)

(continued from previous page)

2000-01-01	-0.986205	-1.719758	-2.230079	-0.439106
2000-01-02	-2.397242	-0.124508	-1.493995	-0.237058
2000-01-03	-1.482014	-0.429889	-0.782186	-0.389666
2000-01-04	-0.480306	-1.051903	-0.987736	-0.182060
2000-01-05	-0.379467	-0.273248	-0.138556	-0.881904
2000-01-06	-0.514897	-0.117796	-0.108906	-1.142649
2000-01-07	-1.349120	-0.316880	-0.128845	-1.352644
2000-01-08	-0.161458	-0.739064	-0.165377	-1.495080

You may wish to set values based on some boolean criteria. This can be done intuitively like so:

In [177]:	s2 = s.copy()			
In [178]:	s2[s2 < 0] = 0			
In [179]:	s2			
Out[179]:				
	4 0			
	3 1			
	2 2			
	1 3			
	0 4			
	dtype: int64			
In [180]:	df2 = df.copy()			
In [181]:	df2[df2 < 0] = 0			
In [182]:	df2			
Out[182]:				
	A B C D			
2000-01-01	0.000000	0.000000	0.000000	0.000000
2000-01-02	0.000000	0.124508	1.493995	0.000000
2000-01-03	0.000000	0.429889	0.000000	0.389666
2000-01-04	0.000000	0.000000	0.000000	0.000000
2000-01-05	0.000000	0.273248	0.000000	0.881904
2000-01-06	0.000000	0.000000	0.000000	0.000000
2000-01-07	0.000000	0.316880	0.000000	0.000000
2000-01-08	0.161458	0.739064	0.165377	0.000000

By default, `where` returns a modified copy of the data. There is an optional parameter `inplace` so that the original data can be modified without creating a copy:

In [183]:	df_orig = df.copy()			
In [184]:	df_orig.where(df > 0, -df, inplace=True)			
In [185]:	df_orig			
Out[185]:				
	A B C D			
2000-01-01	0.986205	1.719758	2.230079	0.439106
2000-01-02	2.397242	0.124508	1.493995	0.237058
2000-01-03	1.482014	0.429889	0.782186	0.389666
2000-01-04	0.480306	1.051903	0.987736	0.182060
2000-01-05	0.379467	0.273248	0.138556	0.881904
2000-01-06	0.514897	0.117796	0.108906	1.142649

(continues on next page)

(continued from previous page)

2000-01-07	1.349120	0.316880	0.128845	1.352644
2000-01-08	0.161458	0.739064	0.165377	1.495080

Note: The signature for `DataFrame.where()` differs from `numpy.where()`. Roughly `df1.where(m, df2)` is equivalent to `np.where(m, df1, df2)`.

```
In [186]: df.where(df < 0, -df) == np.where(df < 0, df, -df)
Out[186]:
```

	A	B	C	D
2000-01-01	True	True	True	True
2000-01-02	True	True	True	True
2000-01-03	True	True	True	True
2000-01-04	True	True	True	True
2000-01-05	True	True	True	True
2000-01-06	True	True	True	True
2000-01-07	True	True	True	True
2000-01-08	True	True	True	True

Alignment

Furthermore, `where` aligns the input boolean condition (ndarray or DataFrame), such that partial selection with setting is possible. This is analogous to partial setting via `.loc` (but on the contents rather than the axis labels).

```
In [187]: df2 = df.copy()
```

```
In [188]: df2[df2[1:4] > 0] = 3
```

```
In [189]: df2
```

```
Out[189]:
```

	A	B	C	D
2000-01-01	-0.986205	-1.719758	-2.230079	-0.439106
2000-01-02	-2.397242	3.000000	3.000000	-0.237058
2000-01-03	-1.482014	3.000000	-0.782186	3.000000
2000-01-04	-0.480306	-1.051903	-0.987736	-0.182060
2000-01-05	-0.379467	0.273248	-0.138556	0.881904
2000-01-06	-0.514897	-0.117796	-0.108906	-1.142649
2000-01-07	-1.349120	0.316880	-0.128845	-1.352644
2000-01-08	0.161458	0.739064	0.165377	-1.495080

Where can also accept `axis` and `level` parameters to align the input when performing the `where`.

```
In [190]: df2 = df.copy()
```

```
In [191]: df2.where(df2 > 0, df2['A'], axis='index')
```

```
Out[191]:
```

	A	B	C	D
2000-01-01	-0.986205	-0.986205	-0.986205	-0.986205
2000-01-02	-2.397242	0.124508	1.493995	-2.397242
2000-01-03	-1.482014	0.429889	-1.482014	0.389666
2000-01-04	-0.480306	-0.480306	-0.480306	-0.480306
2000-01-05	-0.379467	0.273248	-0.379467	0.881904
2000-01-06	-0.514897	-0.514897	-0.514897	-0.514897
2000-01-07	-1.349120	0.316880	-1.349120	-1.349120
2000-01-08	0.161458	0.739064	0.165377	0.161458

This is equivalent to (but faster than) the following.

```
In [192]: df2 = df.copy()

In [193]: df.apply(lambda x, y: x.where(x > 0, y), y=df['A'])

Out[193]:
      A          B          C          D
2000-01-01 -0.986205 -0.986205 -0.986205 -0.986205
2000-01-02 -2.397242  0.124508  1.493995 -2.397242
2000-01-03 -1.482014  0.429889 -1.482014  0.389666
2000-01-04 -0.480306 -0.480306 -0.480306 -0.480306
2000-01-05 -0.379467  0.273248 -0.379467  0.881904
2000-01-06 -0.514897 -0.514897 -0.514897 -0.514897
2000-01-07 -1.349120  0.316880 -1.349120 -1.349120
2000-01-08  0.161458  0.739064  0.165377  0.161458
```

`where` can accept a callable as condition and `other` arguments. The function must be with one argument (the calling Series or DataFrame) and that returns valid output as condition and `other` argument.

```
In [194]: df3 = pd.DataFrame({'A': [1, 2, 3],
                           'B': [4, 5, 6],
                           'C': [7, 8, 9]})

In [195]: df3.where(lambda x: x > 4, lambda x: x + 10)

Out[195]:
      A    B    C
0   11   14   7
1   12   5    8
2   13   6    9
```

Mask

`mask()` is the inverse boolean operation of `where`.

```
In [196]: s.mask(s >= 0)
Out[196]:
4    NaN
3    NaN
2    NaN
1    NaN
0    NaN
dtype: float64

In [197]: df.mask(df >= 0)
Out[197]:
      A          B          C          D
2000-01-01 -0.986205 -1.719758 -2.230079 -0.439106
2000-01-02 -2.397242      NaN      NaN -0.237058
2000-01-03 -1.482014      NaN -0.782186      NaN
2000-01-04 -0.480306 -1.051903 -0.987736 -0.182060
2000-01-05 -0.379467      NaN -0.138556      NaN
2000-01-06 -0.514897 -0.117796 -0.108906 -1.142649
2000-01-07 -1.349120      NaN -0.128845 -1.352644
2000-01-08      NaN      NaN      NaN -1.495080
```

3.2.16 The `query()` Method

`DataFrame` objects have a `query()` method that allows selection using an expression.

You can get the value of the frame where column `b` has values between the values of columns `a` and `c`. For example:

```
In [198]: n = 10

In [199]: df = pd.DataFrame(np.random.rand(n, 3), columns=list('abc'))

In [200]: df
Out[200]:
          a         b         c
0  0.564354  0.446221  0.031135
1  0.902823  0.612305  0.538181
2  0.663245  0.164731  0.782808
3  0.194429  0.253263  0.923684
4  0.698026  0.425477  0.840259
5  0.739830  0.738261  0.105783
6  0.214871  0.824421  0.246428
7  0.821225  0.243330  0.650292
8  0.373653  0.171969  0.479279
9  0.450277  0.365091  0.217416

# pure python
In [201]: df[(df['a'] < df['b']) & (df['b'] < df['c'])]
Out[201]:
          a         b         c
3  0.194429  0.253263  0.923684

# query
In [202]: df.query('(a < b) & (b < c)')
Out[202]:
          a         b         c
3  0.194429  0.253263  0.923684
```

Do the same thing but fall back on a named index if there is no column with the name `a`.

```
In [203]: df = pd.DataFrame(np.random.randint(n / 2, size=(n, 2)), columns=list('bc'))

In [204]: df.index.name = 'a'

In [205]: df
Out[205]:
      b   c
a
0  4   0
1  3   1
2  4   3
3  0   2
4  1   4
5  4   4
6  4   2
7  2   0
8  0   0
9  1   3

In [206]: df.query('a < b and b < c')
```

(continues on next page)

(continued from previous page)

Out [206]:
Empty DataFrame
Columns: [b, c]
Index: []

If instead you don't want to or cannot name your index, you can use the name `index` in your query expression:

In [207]: `df = pd.DataFrame(np.random.randint(n, size=(n, 2)), columns=list('bc'))`

In [208]: `df`

Out [208]:

	b	c
0	4	5
1	4	1
2	0	8
3	4	7
4	0	0
5	8	5
6	1	2
7	4	3
8	1	0
9	6	3

In [209]: `df.query('index < b < c')`

Out [209]:

	b	c
0	4	5
3	4	7

Note: If the name of your index overlaps with a column name, the column name is given precedence. For example,

In [210]: `df = pd.DataFrame({'a': np.random.randint(5, size=5)})`

In [211]: `df.index.name = 'a'`

In [212]: `df.query('a > 2') # uses the column 'a', not the index`

Out [212]:

	a
a	
0	4
1	4
2	3

You can still use the index in a query expression by using the special identifier ‘`index`’:

In [213]: `df.query('index > 2')`

Out [213]:

	a
a	
3	1
4	1

If for some reason you have a column named `index`, then you can refer to the index as `index_level_0` as well, but at this point you should consider renaming your columns to something less ambiguous.

MultiIndex query() Syntax

You can also use the levels of a DataFrame with a `MultiIndex` as if they were columns in the frame:

```
In [214]: n = 10
In [215]: colors = np.random.choice(['red', 'green'], size=n)
In [216]: foods = np.random.choice(['eggs', 'ham'], size=n)
In [217]: colors
Out[217]:
array(['red', 'red', 'green', 'green', 'red', 'red', 'green', 'green',
       'green', 'red'], dtype='|<U5')
In [218]: foods
Out[218]:
array(['eggs', 'ham', 'ham', 'ham', 'ham', 'ham', 'eggs', 'eggs', 'ham',
       'eggs'], dtype='|<U4')
In [219]: index = pd.MultiIndex.from_arrays([colors, foods], names=['color', 'food'])
In [220]: df = pd.DataFrame(np.random.randn(n, 2), index=index)
In [221]: df
Out[221]:
          0         1
color food
red   eggs  0.397240  1.722883
      ham   0.634589  1.761948
green ham  1.191222 -0.748678
      ham  -0.013401 -0.982325
red   ham   0.272726  1.042615
      ham   0.267082  0.191461
green eggs -0.435659 -0.035917
      eggs   0.194931  0.970348
      ham   2.187055  0.383666
red   eggs -0.812383 -0.497327
In [222]: df.query('color == "red"')
Out[222]:
          0         1
color food
red   eggs  0.397240  1.722883
      ham   0.634589  1.761948
      ham   0.272726  1.042615
      ham   0.267082  0.191461
      eggs -0.812383 -0.497327
```

If the levels of the MultiIndex are unnamed, you can refer to them using special names:

```
In [223]: df.index.names = [None, None]
In [224]: df
Out[224]:
          0         1
red   eggs  0.397240  1.722883
      ham   0.634589  1.761948
```

(continues on next page)

(continued from previous page)

```
green ham    1.191222 -0.748678
      ham   -0.013401 -0.982325
red   ham    0.272726  1.042615
      ham    0.267082  0.191461
green eggs  -0.435659 -0.035917
      eggs   0.194931  0.970348
      ham    2.187055  0.383666
red   eggs  -0.812383 -0.497327
```

In [225]: df.query('ilevel_0 == "red"')

Out [225]:

	0	1
red eggs	0.397240	1.722883
ham	0.634589	1.761948
ham	0.272726	1.042615
ham	0.267082	0.191461
eggs	-0.812383	-0.497327

The convention is `ilevel_0`, which means “index level 0” for the 0th level of the `index`.

query() Use Cases

A use case for `query()` is when you have a collection of `DataFrame` objects that have a subset of column names (or index levels/names) in common. You can pass the same query to both frames *without* having to specify which frame you’re interested in querying

In [226]: df = pd.DataFrame(np.random.rand(n, 3), columns=list('abc'))

In [227]: df

Out [227]:

	a	b	c
0	0.483974	0.645639	0.413412
1	0.611039	0.585546	0.848970
2	0.523271	0.811649	0.517849
3	0.947506	0.143525	0.055154
4	0.934891	0.214973	0.271028
5	0.832143	0.777114	0.572133
6	0.304056	0.712288	0.960006
7	0.965451	0.803696	0.866318
8	0.965355	0.383391	0.647743
9	0.639263	0.218103	0.886788

In [228]: df2 = pd.DataFrame(np.random.rand(n + 2, 3), columns=df.columns)

In [229]: df2

Out [229]:

	a	b	c
0	0.563472	0.298326	0.361543
1	0.021200	0.761846	0.279478
2	0.274321	0.127032	0.025433
3	0.789059	0.154680	0.999703
4	0.195936	0.042450	0.475367
5	0.970329	0.053024	0.293762
6	0.877607	0.352530	0.300746
7	0.259895	0.666779	0.920354

(continues on next page)

(continued from previous page)

```
8    0.861035  0.176572  0.638339
9    0.083984  0.834057  0.673247
10   0.190267  0.647251  0.586836
11   0.395322  0.575815  0.184662
```

```
In [230]: expr = '0.0 <= a <= c <= 0.5'
```

```
In [231]: map(lambda frame: frame.query(expr), [df, df2])
Out[231]: <map at 0x7f6d74d2b6d0>
```

query() Python versus pandas Syntax Comparison

Full numpy-like syntax:

```
In [232]: df = pd.DataFrame(np.random.randint(n, size=(n, 3)), columns=list('abc'))
```

```
In [233]: df
```

```
Out[233]:
```

	a	b	c
0	4	1	0
1	9	3	7
2	6	7	9
3	1	9	4
4	6	9	9
5	1	1	2
6	6	6	6
7	9	6	3
8	0	7	9
9	3	8	3

```
In [234]: df.query('(a < b) & (b < c)')
```

```
Out[234]:
```

	a	b	c
2	6	7	9
8	0	7	9

```
In [235]: df[(df['a'] < df['b']) & (df['b'] < df['c'])]
```

```
Out[235]:
```

	a	b	c
2	6	7	9
8	0	7	9

Slightly nicer by removing the parentheses (by binding making comparison operators bind tighter than `&` and `|`).

```
In [236]: df.query('a < b & b < c')
```

```
Out[236]:
```

	a	b	c
2	6	7	9
8	0	7	9

Use English instead of symbols:

```
In [237]: df.query('a < b and b < c')
```

```
Out[237]:
```

	a	b	c
2	6	7	9
8	0	7	9

(continues on next page)

(continued from previous page)

2	6	7	9
8	0	7	9

Pretty close to how you might write it on paper:

```
In [238]: df.query('a < b < c')
Out[238]:
   a   b   c
2  6   7   9
8  0   7   9
```

The `in` and `not in` operators

`query()` also supports special use of Python's `in` and `not in` comparison operators, providing a succinct syntax for calling the `isin` method of a Series or DataFrame.

```
# get all rows where columns "a" and "b" have overlapping values
In [239]: df = pd.DataFrame({'a': list('aabbcdddeeff'), 'b': list('aaaabbbbcccc'),
.....:                               'c': np.random.randint(5, size=12),
.....:                               'd': np.random.randint(9, size=12)})

In [240]: df
Out[240]:
   a   b   c   d
0  a   a   1   5
1  a   a   1   1
2  b   a   4   1
3  b   a   4   3
4  c   b   4   5
5  c   b   0   0
6  d   b   0   4
7  d   b   3   3
8  e   c   4   5
9  e   c   2   0
10 f   c   2   2
11 f   c   4   7

In [241]: df.query('a in b')
Out[241]:
   a   b   c   d
0  a   a   1   5
1  a   a   1   1
2  b   a   4   1
3  b   a   4   3
4  c   b   4   5
5  c   b   0   0

# How you'd do it in pure Python
In [242]: df[df['a'].isin(df['b'])]
Out[242]:
   a   b   c   d
0  a   a   1   5
1  a   a   1   1
2  b   a   4   1
```

(continues on next page)

(continued from previous page)

```
3   b   a   4   3
4   c   b   4   5
5   c   b   0   0

In [243]: df.query('a not in b')
Out[243]:
      a   b   c   d
6   d   b   0   4
7   d   b   3   3
8   e   c   4   5
9   e   c   2   0
10  f   c   2   2
11  f   c   4   7

# pure Python
In [244]: df[~df['a'].isin(df['b'])]
Out[244]:
      a   b   c   d
6   d   b   0   4
7   d   b   3   3
8   e   c   4   5
9   e   c   2   0
10  f   c   2   2
11  f   c   4   7
```

You can combine this with other expressions for very succinct queries:

```
# rows where cols a and b have overlapping values
# and col c's values are less than col d's
In [245]: df.query('a in b and c < d')
Out[245]:
      a   b   c   d
0   a   a   1   5
4   c   b   4   5

# pure Python
In [246]: df[df['b'].isin(df['a']) & (df['c'] < df['d'])]
Out[246]:
      a   b   c   d
0   a   a   1   5
4   c   b   4   5
6   d   b   0   4
8   e   c   4   5
11  f   c   4   7
```

Note: Note that `in` and `not in` are evaluated in Python, since `numexpr` has no equivalent of this operation. However, **only the `in/not in` expression itself** is evaluated in vanilla Python. For example, in the expression

```
df.query('a in b + c + d')
```

`(b + c + d)` is evaluated by `numexpr` and *then* the `in` operation is evaluated in plain Python. In general, any operations that can be evaluated using `numexpr` will be.

Special use of the == operator with list objects

Comparing a list of values to a column using ==/!= works similarly to in/not in.

```
In [247]: df.query('b == ["a", "b", "c"]')
```

```
Out[247]:
```

	a	b	c	d
0	a	a	1	5
1	a	a	1	1
2	b	a	4	1
3	b	a	4	3
4	c	b	4	5
5	c	b	0	0
6	d	b	0	4
7	d	b	3	3
8	e	c	4	5
9	e	c	2	0
10	f	c	2	2
11	f	c	4	7

```
# pure Python
```

```
In [248]: df[df['b'].isin(["a", "b", "c"])]
```

```
Out[248]:
```

	a	b	c	d
0	a	a	1	5
1	a	a	1	1
2	b	a	4	1
3	b	a	4	3
4	c	b	4	5
5	c	b	0	0
6	d	b	0	4
7	d	b	3	3
8	e	c	4	5
9	e	c	2	0
10	f	c	2	2
11	f	c	4	7

```
In [249]: df.query('c == [1, 2]')
```

```
Out[249]:
```

	a	b	c	d
0	a	a	1	5
1	a	a	1	1
9	e	c	2	0
10	f	c	2	2

```
In [250]: df.query('c != [1, 2]')
```

```
Out[250]:
```

	a	b	c	d
2	b	a	4	1
3	b	a	4	3
4	c	b	4	5
5	c	b	0	0
6	d	b	0	4
7	d	b	3	3
8	e	c	4	5
11	f	c	4	7

```
# using in/not in
```

(continues on next page)

(continued from previous page)

```
In [251]: df.query('[1, 2] in c')
Out[251]:
   a   b   c   d
0  a   a   1   5
1  a   a   1   1
9  e   c   2   0
10 f   c   2   2

In [252]: df.query('[1, 2] not in c')
Out[252]:
   a   b   c   d
2  b   a   4   1
3  b   a   4   3
4  c   b   4   5
5  c   b   0   0
6  d   b   0   4
7  d   b   3   3
8  e   c   4   5
11 f   c   4   7

# pure Python
In [253]: df[df['c'].isin([1, 2])]
Out[253]:
   a   b   c   d
0  a   a   1   5
1  a   a   1   1
9  e   c   2   0
10 f   c   2   2
```

Boolean operators

You can negate boolean expressions with the word `not` or the `~` operator.

```
In [254]: df = pd.DataFrame(np.random.rand(n, 3), columns=list('abc'))
In [255]: df['bools'] = np.random.rand(len(df)) > 0.5
In [256]: df.query('~bools')
Out[256]:
         a         b         c  bools
0  0.499604  0.981560  0.137759  False
4  0.104751  0.782568  0.977198  False
7  0.973197  0.245000  0.977406  False
9  0.805940  0.451425  0.070470  False

In [257]: df.query('not bools')
Out[257]:
         a         b         c  bools
0  0.499604  0.981560  0.137759  False
4  0.104751  0.782568  0.977198  False
7  0.973197  0.245000  0.977406  False
9  0.805940  0.451425  0.070470  False

In [258]: df.query('not bools') == df[~df['bools']]
Out[258]:
```

(continues on next page)

(continued from previous page)

	a	b	c	bools
0	True	True	True	True
4	True	True	True	True
7	True	True	True	True
9	True	True	True	True

Of course, expressions can be arbitrarily complex too:

```
# short query syntax
In [259]: shorter = df.query('a < b < c and (not bools) or bools > 2')

# equivalent in pure Python
In [260]: longer = df[(df['a'] < df['b'])
.....:             & (df['b'] < df['c'])
.....:             & (~df['bools']))
.....:             | (df['bools'] > 2)]
.....:

In [261]: shorter
Out[261]:
      a          b          c  bools
4  0.104751  0.782568  0.977198  False

In [262]: longer
Out[262]:
      a          b          c  bools
4  0.104751  0.782568  0.977198  False

In [263]: shorter == longer
Out[263]:
```

	a	b	c	bools
4	True	True	True	True

Performance of query()

DataFrame.query() using numexpr is slightly faster than Python for large frames.

Note: You will only see the performance benefits of using the `numexpr` engine with `DataFrame.query()` if your frame has more than approximately 200,000 rows.

This plot was created using a `DataFrame` with 3 columns each containing floating point values generated using `numpy.random.randn()`.

3.2.17 Duplicate data

If you want to identify and remove duplicate rows in a DataFrame, there are two methods that will help: `duplicated` and `drop_duplicates`. Each takes as an argument the columns to use to identify duplicated rows.

- `duplicated` returns a boolean vector whose length is the number of rows, and which indicates whether a row is duplicated.
- `drop_duplicates` removes duplicate rows.

By default, the first observed row of a duplicate set is considered unique, but each method has a `keep` parameter to specify targets to be kept.

- `keep='first'` (default): mark / drop duplicates except for the first occurrence.
- `keep='last'`: mark / drop duplicates except for the last occurrence.
- `keep=False`: mark / drop all duplicates.

```
In [264]: df2 = pd.DataFrame({'a': ['one', 'one', 'two', 'two', 'two', 'three', 'four',
       ],
       ....:                   'b': ['x', 'y', 'x', 'y', 'x', 'x', 'x'],
       ....:                   'c': np.random.randn(7)})

In [265]: df2
Out[265]:
   a   b      c
0  one  x -0.086643
1  one  y -0.862428
2  two  x  1.155986
3  two  y -0.583644
4  two  x -1.416461
5  three  x  0.799196
6  four  x -2.063856

In [266]: df2.duplicated('a')
Out[266]:
0    False
1     True
2    False
3     True
4     True
5    False
6    False
dtype: bool

In [267]: df2.duplicated('a', keep='last')
Out[267]:
0     True
1    False
2     True
3     True
4    False
5    False
6    False
dtype: bool

In [268]: df2.duplicated('a', keep=False)
```

(continues on next page)

(continued from previous page)

```
0    True
1    True
2    True
3    True
4    True
5   False
6   False
dtype: bool

In [269]: df2.drop_duplicates('a')
Out[269]:
      a   b       c
0  one  x -0.086643
2  two  x  1.155986
5 three  x  0.799196
6 four  x -2.063856

In [270]: df2.drop_duplicates('a', keep='last')
Out[270]:
      a   b       c
1  one  y -0.862428
4  two  x -1.416461
5 three  x  0.799196
6 four  x -2.063856

In [271]: df2.drop_duplicates('a', keep=False)
Out[271]:
      a   b       c
5 three  x  0.799196
6 four  x -2.063856
```

Also, you can pass a list of columns to identify duplicates.

```
In [272]: df2.duplicated(['a', 'b'])
Out[272]:
0    False
1    False
2    False
3    False
4    True
5    False
6    False
dtype: bool

In [273]: df2.drop_duplicates(['a', 'b'])
Out[273]:
      a   b       c
0  one  x -0.086643
1  one  y -0.862428
2  two  x  1.155986
3  two  y -0.583644
5 three  x  0.799196
6 four  x -2.063856
```

To drop duplicates by index value, use `Index.duplicated` then perform slicing. The same set of options are available for the `keep` parameter.

```
In [274]: df3 = pd.DataFrame({'a': np.arange(6),
.....:                      'b': np.random.randn(6)},
.....:                      index=['a', 'a', 'b', 'c', 'b', 'a'])

In [275]: df3
Out[275]:
   a      b
a  0 -0.457673
a  1  0.315795
b  2 -0.013959
c  3 -0.376069
b  4 -0.715356
a  5  1.802760

In [276]: df3.index.duplicated()
Out[276]: array([False,  True, False, False,  True,  True])

In [277]: df3[~df3.index.duplicated()]
Out[277]:
   a      b
a  0 -0.457673
b  2 -0.013959
c  3 -0.376069

In [278]: df3[~df3.index.duplicated(keep='last')]
Out[278]:
   a      b
c  3 -0.376069
b  4 -0.715356
a  5  1.802760

In [279]: df3[~df3.index.duplicated(keep=False)]
Out[279]:
   a      b
c  3 -0.376069
```

3.2.18 Dictionary-like get() method

Each of Series or DataFrame have a `get` method which can return a default value.

```
In [280]: s = pd.Series([1, 2, 3], index=['a', 'b', 'c'])

In [281]: s.get('a')  # equivalent to s['a']
Out[281]: 1

In [282]: s.get('x', default=-1)
Out[282]: -1
```

3.2.19 The `lookup()` method

Sometimes you want to extract a set of values given a sequence of row labels and column labels, and the `lookup` method allows for this and returns a NumPy array. For instance:

```
In [283]: dflookup = pd.DataFrame(np.random.rand(20, 4), columns = ['A', 'B', 'C', 'D'])
          ↵

In [284]: dflookup.lookup(list(range(0, 10, 2)), ['B', 'C', 'A', 'B', 'D'])
Out[284]: array([0.85612986, 0.02825952, 0.99403226, 0.02263787, 0.37166623])
```

3.2.20 Index objects

The pandas `Index` class and its subclasses can be viewed as implementing an *ordered multiset*. Duplicates are allowed. However, if you try to convert an `Index` object with duplicate entries into a `set`, an exception will be raised.

`Index` also provides the infrastructure necessary for lookups, data alignment, and reindexing. The easiest way to create an `Index` directly is to pass a list or other sequence to `Index`:

```
In [285]: index = pd.Index(['e', 'd', 'a', 'b'])

In [286]: index
Out[286]: Index(['e', 'd', 'a', 'b'], dtype='object')

In [287]: 'd' in index
Out[287]: True
```

You can also pass a name to be stored in the index:

```
In [288]: index = pd.Index(['e', 'd', 'a', 'b'], name='something')

In [289]: index.name
Out[289]: 'something'
```

The name, if set, will be shown in the console display:

```
In [290]: index = pd.Index(list(range(5)), name='rows')

In [291]: columns = pd.Index(['A', 'B', 'C'], name='cols')

In [292]: df = pd.DataFrame(np.random.randn(5, 3), index=index, columns=columns)

In [293]: df
Out[293]:
   cols      A        B        C
   rows
0     -1.539526  0.083551  1.819217
1     -0.556258 -1.013751  0.804958
2      1.138849 -0.913212  2.047493
3     -0.894783  1.059103 -0.605857
4     -1.096832  0.217643  2.122047

In [294]: df['A']
Out[294]:
   rows
0     -1.539526
1     -0.556258
2      1.138849
3     -0.894783
4     -1.096832
```

(continues on next page)

(continued from previous page)

```
0    -1.539526
1    -0.556258
2     1.138849
3    -0.894783
4    -1.096832
Name: A, dtype: float64
```

Setting metadata

Indexes are “mostly immutable”, but it is possible to set and change their metadata, like the index name (or, for MultiIndex, levels and codes).

You can use the `rename`, `set_names`, `set_levels`, and `set_codes` to set these attributes directly. They default to returning a copy; however, you can specify `inplace=True` to have the data change in place.

See [Advanced Indexing](#) for usage of MultiIndexes.

```
In [295]: ind = pd.Index([1, 2, 3])

In [296]: ind.rename("apple")
Out[296]: Int64Index([1, 2, 3], dtype='int64', name='apple')

In [297]: ind
Out[297]: Int64Index([1, 2, 3], dtype='int64')

In [298]: ind.set_names(["apple"], inplace=True)

In [299]: ind.name = "bob"

In [300]: ind
Out[300]: Int64Index([1, 2, 3], dtype='int64', name='bob')
```

`set_names`, `set_levels`, and `set_codes` also take an optional `level` argument

```
In [301]: index = pd.MultiIndex.from_product([range(3), ['one', 'two']], names=['first',
   'second'])

In [302]: index
Out[302]:
MultiIndex([(0, 'one'),
            (0, 'two'),
            (1, 'one'),
            (1, 'two'),
            (2, 'one'),
            (2, 'two')]),
            names=['first', 'second'])

In [303]: index.levels[1]
Out[303]: Index(['one', 'two'], dtype='object', name='second')

In [304]: index.set_levels(["a", "b"], level=1)
Out[304]:
MultiIndex([(0, 'a'),
            (0, 'b'),
            (1, 'a'),
            (1, 'b')])
```

(continues on next page)

(continued from previous page)

```
(2, 'a'),  
(2, 'b')],  
names=['first', 'second'])
```

Set operations on Index objects

The two main operations are `union` (`|`) and `intersection` (`&`). These can be directly called as instance methods or used via overloaded operators. Difference is provided via the `.difference()` method.

```
In [305]: a = pd.Index(['c', 'b', 'a'])  
  
In [306]: b = pd.Index(['c', 'e', 'd'])  
  
In [307]: a | b  
Out[307]: Index(['a', 'b', 'c', 'd', 'e'], dtype='object')  
  
In [308]: a & b  
Out[308]: Index(['c'], dtype='object')  
  
In [309]: a.difference(b)  
Out[309]: Index(['a', 'b'], dtype='object')
```

Also available is the `symmetric_difference` (`^`) operation, which returns elements that appear in either `idx1` or `idx2`, but not in both. This is equivalent to the `Index` created by `idx1.difference(idx2).union(idx2.difference(idx1))`, with duplicates dropped.

```
In [310]: idx1 = pd.Index([1, 2, 3, 4])  
  
In [311]: idx2 = pd.Index([2, 3, 4, 5])  
  
In [312]: idx1.symmetric_difference(idx2)  
Out[312]: Int64Index([1, 5], dtype='int64')  
  
In [313]: idx1 ^ idx2  
Out[313]: Int64Index([1, 5], dtype='int64')
```

Note: The resulting index from a set operation will be sorted in ascending order.

When performing `Index.union()` between indexes with different dtypes, the indexes must be cast to a common dtype. Typically, though not always, this is object dtype. The exception is when performing a union between integer and float data. In this case, the integer values are converted to float

```
In [314]: idx1 = pd.Index([0, 1, 2])  
  
In [315]: idx2 = pd.Index([0.5, 1.5])  
  
In [316]: idx1 | idx2  
Out[316]: Float64Index([0.0, 0.5, 1.0, 1.5, 2.0], dtype='float64')
```

Missing values

Important: Even though `Index` can hold missing values (`NaN`), it should be avoided if you do not want any unexpected results. For example, some operations exclude missing values implicitly.

`Index.fillna` fills missing values with specified scalar value.

```
In [317]: idx1 = pd.Index([1, np.nan, 3, 4])

In [318]: idx1
Out[318]: Float64Index([1.0, nan, 3.0, 4.0], dtype='float64')

In [319]: idx1.fillna(2)
Out[319]: Float64Index([1.0, 2.0, 3.0, 4.0], dtype='float64')

In [320]: idx2 = pd.DatetimeIndex([pd.Timestamp('2011-01-01'),
.....:                     pd.NaT,
.....:                     pd.Timestamp('2011-01-03')])
.....:

In [321]: idx2
Out[321]: DatetimeIndex(['2011-01-01', 'NaT', '2011-01-03'], dtype='datetime64[ns]', freq=None)

In [322]: idx2.fillna(pd.Timestamp('2011-01-02'))
Out[322]: DatetimeIndex(['2011-01-01', '2011-01-02', '2011-01-03'], dtype='datetime64[ns]', freq=None)
```

3.2.21 Set / reset index

Occasionally you will load or create a data set into a `DataFrame` and want to add an index after you've already done so. There are a couple of different ways.

Set an index

`DataFrame` has a `set_index()` method which takes a column name (for a regular `Index`) or a list of column names (for a `MultiIndex`). To create a new, re-indexed `DataFrame`:

```
In [323]: data
Out[323]:
     a    b    c    d
0  bar   one   z  1.0
1  bar   two   y  2.0
2  foo   one   x  3.0
3  foo   two   w  4.0

In [324]: indexed1 = data.set_index('c')

In [325]: indexed1
Out[325]:
     a    b    d
c
z  bar   one  1.0
```

(continues on next page)

(continued from previous page)

```
y   bar   two   2.0
x   foo   one   3.0
w   foo   two   4.0

In [326]: indexed2 = data.set_index(['a', 'b'])

In [327]: indexed2
Out[327]:
      c    d
a   b
bar one  z  1.0
      two  y  2.0
foo one  x  3.0
      two  w  4.0
```

The append keyword option allow you to keep the existing index and append the given columns to a MultiIndex:

```
In [328]: frame = data.set_index('c', drop=False)

In [329]: frame = frame.set_index(['a', 'b'], append=True)

In [330]: frame
Out[330]:
      c    d
c a   b
z bar one  z  1.0
y bar two  y  2.0
x foo one  x  3.0
w foo two  w  4.0
```

Other options in set_index allow you not drop the index columns or to add the index in-place (without creating a new object):

```
In [331]: data.set_index('c', drop=False)
Out[331]:
      a    b    c    d
c
z   bar   one   z  1.0
y   bar   two   y  2.0
x   foo   one   x  3.0
w   foo   two   w  4.0

In [332]: data.set_index(['a', 'b'], inplace=True)

In [333]: data
Out[333]:
      c    d
a   b
bar one  z  1.0
      two  y  2.0
foo one  x  3.0
      two  w  4.0
```

Reset the index

As a convenience, there is a new function on DataFrame called `reset_index()` which transfers the index values into the DataFrame's columns and sets a simple integer index. This is the inverse operation of `set_index()`.

```
In [334]: data
Out[334]:
      c    d
a   b
bar one z  1.0
     two y  2.0
foo one x  3.0
     two w  4.0

In [335]: data.reset_index()
Out[335]:
   a   b   c   d
0 bar one z  1.0
1 bar two y  2.0
2 foo one x  3.0
3 foo two w  4.0
```

The output is more similar to a SQL table or a record array. The names for the columns derived from the index are the ones stored in the `names` attribute.

You can use the `level` keyword to remove only a portion of the index:

```
In [336]: frame
Out[336]:
      c    d
c a   b
z bar one z  1.0
y bar two y  2.0
x foo one x  3.0
w foo two w  4.0

In [337]: frame.reset_index(level=1)
Out[337]:
      a   c   d
c b
z one  bar z  1.0
y two  bar y  2.0
x one  foo x  3.0
w two  foo w  4.0
```

`reset_index` takes an optional parameter `drop` which if true simply discards the index, instead of putting index values in the DataFrame's columns.

Adding an ad hoc index

If you create an index yourself, you can just assign it to the `index` field:

```
data.index = index
```

3.2.22 Returning a view versus a copy

When setting values in a pandas object, care must be taken to avoid what is called `chained indexing`. Here is an example.

```
In [338]: dfmi = pd.DataFrame([list('abcd'),
.....:                   list('efgh'),
.....:                   list('ijkl'),
.....:                   list('mnop')],
.....:                   columns=pd.MultiIndex.from_product([[['one', 'two'],
.....:                                         ['first', 'second']
.....:                                         ]]))
.....:

In [339]: dfmi
Out[339]:
   one      two
   first second first second
0    a      b    c      d
1    e      f    g      h
2    i      j    k      l
3    m      n    o      p
```

Compare these two access methods:

```
In [340]: dfmi['one']['second']
Out[340]:
0    b
1    f
2    j
3    n
Name: second, dtype: object
```

```
In [341]: dfmi.loc[:, ('one', 'second')]
Out[341]:
0    b
1    f
2    j
3    n
Name: (one, second), dtype: object
```

These both yield the same results, so which should you use? It is instructive to understand the order of operations on these and why method 2 (`.loc`) is much preferred over method 1 (chained `[]`).

`dfmi['one']` selects the first level of the columns and returns a DataFrame that is singly-indexed. Then another Python operation `dfmi_with_one['second']` selects the series indexed by `'second'`. This is indicated by the variable `dfmi_with_one` because pandas sees these operations as separate events. e.g. separate calls to `__getitem__`, so it has to treat them as linear operations, they happen one after another.

Contrast this to `df.loc[:, ('one', 'second')]` which passes a nested tuple of `(slice(None), ('one', 'second'))` to a single call to `__getitem__`. This allows pandas to deal with this as a single entity. Furthermore

this order of operations *can* be significantly faster, and allows one to index *both* axes if so desired.

Why does assignment fail when using chained indexing?

The problem in the previous section is just a performance issue. What's up with the `SettingWithCopy` warning? We don't **usually** throw warnings around when you do something that might cost a few extra milliseconds!

But it turns out that assigning to the product of chained indexing has inherently unpredictable results. To see this, think about how the Python interpreter executes this code:

```
dfmi.loc[:, ('one', 'second')] = value
# becomes
dfmi.loc.__setitem__(slice(None), ('one', 'second')), value)
```

But this code is handled differently:

```
dfmi['one']['second'] = value
# becomes
dfmi.__getitem__('one').__setitem__('second', value)
```

See that `__getitem__` in there? Outside of simple cases, it's very hard to predict whether it will return a view or a copy (it depends on the memory layout of the array, about which pandas makes no guarantees), and therefore whether the `__setitem__` will modify `dfmi` or a temporary object that gets thrown out immediately afterward. **That's** what `SettingWithCopy` is warning you about!

Note: You may be wondering whether we should be concerned about the `loc` property in the first example. But `dfmi.loc` is guaranteed to be `dfmi` itself with modified indexing behavior, so `dfmi.loc.__getitem__` / `dfmi.loc.__setitem__` operate on `dfmi` directly. Of course, `dfmi.loc.__getitem__(idx)` may be a view or a copy of `dfmi`.

Sometimes a `SettingWithCopy` warning will arise at times when there's no obvious chained indexing going on. **These** are the bugs that `SettingWithCopy` is designed to catch! Pandas is probably trying to warn you that you've done this:

```
def do_something(df):
    foo = df[['bar', 'baz']]  # Is foo a view? A copy? Nobody knows!
    # ... many lines here ...
    # We don't know whether this will modify df or not!
    foo['quux'] = value
    return foo
```

Yikes!

Evaluation order matters

When you use chained indexing, the order and type of the indexing operation partially determine whether the result is a slice into the original object, or a copy of the slice.

Pandas has the `SettingWithCopyWarning` because assigning to a copy of a slice is frequently not intentional, but a mistake caused by chained indexing returning a copy where a slice was expected.

If you would like pandas to be more or less trusting about assignment to a chained indexing expression, you can set the `option.mode.chained_assignment` to one of these values:

- 'warn', the default, means a `SettingWithCopyWarning` is printed.

- 'raise' means pandas will raise a `SettingWithCopyException` you have to deal with.
- None will suppress the warnings entirely.

```
In [342]: dfb = pd.DataFrame({'a': ['one', 'one', 'two',
.....:                               'three', 'two', 'one', 'six'],
.....:                               'c': np.arange(7)})

# This will show the SettingWithCopyWarning
# but the frame values will be set
In [343]: dfb['c'][dfb['a'].str.startswith('o')] = 42
```

This however is operating on a copy and will not work.

```
>>> pd.set_option('mode.chained_assignment','warn')
>>> dfb[dfb['a'].str.startswith('o')]['c'] = 42
Traceback (most recent call last)
...
SettingWithCopyWarning:
  A value is trying to be set on a copy of a slice from a DataFrame.
  Try using .loc[row_index,col_indexer] = value instead
```

A chained assignment can also crop up in setting in a mixed dtype frame.

Note: These setting rules apply to all of `.loc/.iloc`.

This is the correct access method:

```
In [344]: dfc = pd.DataFrame({'A': ['aaa', 'bbb', 'ccc'], 'B': [1, 2, 3]})

In [345]: dfc.loc[0, 'A'] = 11

In [346]: dfc
Out[346]:
   A    B
0  11   1
1  bbb  2
2  ccc  3
```

This *can* work at times, but it is not guaranteed to, and therefore should be avoided:

```
In [347]: dfc = dfc.copy()

In [348]: dfc['A'][0] = 111

In [349]: dfc
Out[349]:
   A    B
0  111  1
1  bbb  2
2  ccc  3
```

This will **not** work at all, and so should be avoided:

```
>>> pd.set_option('mode.chained_assignment','raise')
>>> dfc.loc[0]['A'] = 1111
```

(continues on next page)

(continued from previous page)

```
Traceback (most recent call last)
...
SettingWithCopyException:
  A value is trying to be set on a copy of a slice from a DataFrame.
  Try using .loc[row_index,col_indexer] = value instead
```

Warning: The chained assignment warnings / exceptions are aiming to inform the user of a possibly invalid assignment. There may be false positives; situations where a chained assignment is inadvertently reported.

```

```

3.3 MultiIndex / advanced indexing

This section covers [indexing with a MultiIndex](#) and [other advanced indexing features](#).

See the [Indexing and Selecting Data](#) for general indexing documentation.

Warning: Whether a copy or a reference is returned for a setting operation may depend on the context. This is sometimes called [chained assignment](#) and should be avoided. See [Returning a View versus Copy](#).

See the [cookbook](#) for some advanced strategies.

3.3.1 Hierarchical indexing (MultiIndex)

Hierarchical / Multi-level indexing is very exciting as it opens the door to some quite sophisticated data analysis and manipulation, especially for working with higher dimensional data. In essence, it enables you to store and manipulate data with an arbitrary number of dimensions in lower dimensional data structures like `Series` (1d) and `DataFrame` (2d).

In this section, we will show what exactly we mean by “hierarchical” indexing and how it integrates with all of the pandas indexing functionality described above and in prior sections. Later, when discussing [group by](#) and [pivoting and reshaping data](#), we’ll show non-trivial applications to illustrate how it aids in structuring data for analysis.

See the [cookbook](#) for some advanced strategies.

Changed in version 0.24.0: `MultiIndex.labels` has been renamed to `MultiIndex.codes` and `MultiIndex.set_labels` to `MultiIndex.set_codes`.

Creating a MultiIndex (hierarchical index) object

The `MultiIndex` object is the hierarchical analogue of the standard `Index` object which typically stores the axis labels in pandas objects. You can think of `MultiIndex` as an array of tuples where each tuple is unique. A `MultiIndex` can be created from a list of arrays (using `MultiIndex.from_arrays()`), an array of tuples (using `MultiIndex.from_tuples()`), a crossed set of iterables (using `MultiIndex.from_product()`), or a `DataFrame` (using `MultiIndex.from_frame()`). The `Index` constructor will attempt to return a `MultiIndex` when it is passed a list of tuples. The following examples demonstrate different ways to initialize `MultiIndexes`.

```
In [1]: arrays = [['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'],
...:                 ['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two']]
...:

In [2]: tuples = list(zip(*arrays))

In [3]: tuples
Out[3]:
[('bar', 'one'),
 ('bar', 'two'),
 ('baz', 'one'),
 ('baz', 'two'),
 ('foo', 'one'),
 ('foo', 'two'),
 ('qux', 'one'),
 ('qux', 'two')]

In [4]: index = pd.MultiIndex.from_tuples(tuples, names=['first', 'second'])

In [5]: index
Out[5]:
MultiIndex([(bar, 'one'),
             (bar, 'two'),
             (baz, 'one'),
             (baz, 'two'),
             (foo, 'one'),
             (foo, 'two'),
             (qux, 'one'),
             (qux, 'two')],
            names=['first', 'second'])

In [6]: s = pd.Series(np.random.randn(8), index=index)

In [7]: s
Out[7]:
first   second
bar     one      -0.036812
          two       0.170484
baz     one      -0.783692
          two      -0.971745
foo     one      -0.018594
          two      -0.036161
qux     one      -0.467700
          two      -0.518070
dtype: float64
```

When you want every pairing of the elements in two iterables, it can be easier to use the `MultiIndex.from_product()` method:

```
In [8]: iterables = [['bar', 'baz', 'foo', 'qux'], ['one', 'two']]

In [9]: pd.MultiIndex.from_product(iterables, names=['first', 'second'])
Out[9]:
MultiIndex([(bar, 'one'),
             (bar, 'two'),
             (baz, 'one'),
             (baz, 'two'),
```

(continues on next page)

(continued from previous page)

```
('foo', 'one'),
('foo', 'two'),
('qux', 'one'),
('qux', 'two')],
names=['first', 'second'])
```

You can also construct a MultiIndex from a DataFrame directly, using the method `MultiIndex.from_frame()`. This is a complementary method to `MultiIndex.to_frame()`.

New in version 0.24.0.

```
In [10]: df = pd.DataFrame([['bar', 'one'], ['bar', 'two'],
....:                         ['foo', 'one'], ['foo', 'two']],
....:                         columns=['first', 'second'])

In [11]: pd.MultiIndex.from_frame(df)
Out[11]:
MultiIndex([('bar', 'one'),
            ('bar', 'two'),
            ('foo', 'one'),
            ('foo', 'two')],
           names=['first', 'second'])
```

As a convenience, you can pass a list of arrays directly into Series or DataFrame to construct a MultiIndex automatically:

```
In [12]: arrays = [np.array(['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux']),
....:             np.array(['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two'])]
....:

In [13]: s = pd.Series(np.random.randn(8), index=arrays)

In [14]: s
Out[14]:
bar one    -0.175866
      two    -0.387992
baz one    -1.549540
      two     1.271618
foo one    -2.640141
      two    -0.399375
qux one     0.432241
      two    -0.409477
dtype: float64

In [15]: df = pd.DataFrame(np.random.randn(8, 4), index=arrays)

In [16]: df
Out[16]:
       0         1         2         3
bar one -1.067923 -0.529751  0.851759 -0.255658
      two -1.632789 -0.611335  0.797026 -0.836865
baz one  0.232811 -0.167906 -1.124929 -0.280364
      two -0.238520 -0.612912  0.857719 -1.669450
foo one  0.810455  2.137516  1.571292  0.280772
      two  0.751430 -0.139370 -0.072241  1.136012
qux one -0.471221 -0.870762  1.798508  0.791025
```

(continues on next page)

(continued from previous page)

```
two -0.099136 -0.647270 -0.249042 -0.124511
```

All of the `MultiIndex` constructors accept a `names` argument which stores string names for the levels themselves. If no names are provided, `None` will be assigned:

```
In [17]: df.index.names
Out[17]: FrozenList([None, None])
```

This index can back any axis of a pandas object, and the number of `levels` of the index is up to you:

```
In [18]: df = pd.DataFrame(np.random.randn(3, 8), index=['A', 'B', 'C'],
                           columns=index)

In [19]: df
Out[19]:
first      bar          baz          foo          qux
second     one         two         one         two         one         two
A      -0.950344  0.696571  0.146563  0.270220  0.441303 -0.649521 -1.010702 -0.260359
B      -0.360387 -1.061247  1.394812  0.388240  0.337071 -0.997727 -0.101030 -1.590843
C       0.689151 -0.021507 -0.773364 -2.190632 -2.321281 -2.108470 -0.487524  0.232929

In [20]: pd.DataFrame(np.random.randn(6, 6), index=index[:6], columns=index[:6])
Out[20]:
first      bar          baz          foo
second     one         two         one         two
first second
bar   one      0.835647  0.095388 -0.706684 -0.223572 -0.567985 -1.796847
      two      0.871763  0.850233 -0.456391  0.022351  0.096689 -0.517739
baz   one      0.494843  0.750142  0.249397 -1.445985  0.491900 -0.848223
      two      -0.824648 -0.361235 -0.196476 -0.715570  1.335271 -0.679073
foo   one      -0.123016 -1.596193 -0.315379  0.857300 -0.769244 -0.985251
      two      -0.166979 -2.442267  0.338780  1.970551 -1.631793 -1.023203
```

We've "sparsified" the higher levels of the indexes to make the console output a bit easier on the eyes. Note that how the index is displayed can be controlled using the `multi_sparse` option in `pandas.set_options()`:

```
In [21]: with pd.option_context('display.multi_sparse', False):
    ....:     df
    ....:
```

It's worth keeping in mind that there's nothing preventing you from using tuples as atomic labels on an axis:

```
In [22]: pd.Series(np.random.randn(8), index=tuples)
Out[22]:
(bar, one)    -1.653325
(bar, two)    -0.629308
(baz, one)     0.269513
(baz, two)    -0.625490
(foo, one)     0.193768
(foo, two)     1.160136
(qux, one)    -0.532220
(qux, two)    -0.240162
dtype: float64
```

The reason that the `MultiIndex` matters is that it can allow you to do grouping, selection, and reshaping operations as we will describe below and in subsequent areas of the documentation. As you will see in later sections, you can find

yourself working with hierarchically-indexed data without creating a `MultiIndex` explicitly yourself. However, when loading data from a file, you may wish to generate your own `MultiIndex` when preparing the data set.

Reconstructing the level labels

The method `get_level_values()` will return a vector of the labels for each location at a particular level:

```
In [23]: index.get_level_values(0)
Out[23]: Index(['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'], dtype='object
           ', name='first')

In [24]: index.get_level_values('second')
Out[24]: Index(['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two'], dtype='object
           ', name='second')
```

Basic indexing on axis with MultiIndex

One of the important features of hierarchical indexing is that you can select data by a “partial” label identifying a subgroup in the data. **Partial** selection “drops” levels of the hierarchical index in the result in a completely analogous way to selecting a column in a regular DataFrame:

```
In [25]: df['bar']
Out[25]:
second      one      two
A     -0.950344  0.696571
B     -0.360387 -1.061247
C      0.689151 -0.021507

In [26]: df['bar', 'one']
Out[26]:
A    -0.950344
B    -0.360387
C     0.689151
Name: (bar, one), dtype: float64

In [27]: df['bar']['one']
Out[27]:
A    -0.950344
B    -0.360387
C     0.689151
Name: one, dtype: float64

In [28]: s['qux']
Out[28]:
one    0.432241
two   -0.409477
dtype: float64
```

See [Cross-section with hierarchical index](#) for how to select on a deeper level.

Defined levels

The MultiIndex keeps all the defined levels of an index, even if they are not actually used. When slicing an index, you may notice this. For example:

```
In [29]: df.columns.levels # original MultiIndex
Out[29]: FrozenList([['bar', 'baz', 'foo', 'qux'], ['one', 'two']])

In [30]: df[['foo', 'qux']].columns.levels # sliced
Out[30]: FrozenList([['bar', 'baz', 'foo', 'qux'], ['one', 'two']])
```

This is done to avoid a recomputation of the levels in order to make slicing highly performant. If you want to see only the used levels, you can use the `get_level_values()` method.

```
In [31]: df[['foo', 'qux']].columns.to_numpy()
Out[31]:
array([('foo', 'one'), ('foo', 'two'), ('qux', 'one'), ('qux', 'two')],
      dtype=object)

# for a specific level
In [32]: df[['foo', 'qux']].columns.get_level_values(0)
Out[32]: Index(['foo', 'foo', 'qux', 'qux'], dtype='object', name='first')
```

To reconstruct the MultiIndex with only the used levels, the `remove_unused_levels()` method may be used.

```
In [33]: new_mi = df[['foo', 'qux']].columns.remove_unused_levels()

In [34]: new_mi.levels
Out[34]: FrozenList([['foo', 'qux'], ['one', 'two']])
```

Data alignment and using `reindex`

Operations between differently-indexed objects having MultiIndex on the axes will work as you expect; data alignment will work the same as an Index of tuples:

```
In [35]: s + s[:-2]
Out[35]:
bar  one    -0.351733
      two    -0.775985
baz  one    -3.099081
      two     2.543237
foo  one    -5.280283
      two    -0.798751
qux  one       NaN
      two       NaN
dtype: float64

In [36]: s + s[::2]
Out[36]:
bar  one    -0.351733
      two       NaN
baz  one    -3.099081
      two       NaN
foo  one    -5.280283
      two       NaN
qux  one     0.864482
```

(continues on next page)

(continued from previous page)

```
two      NaN
dtype: float64
```

The `reindex()` method of Series/DataFrames can be called with another MultiIndex, or even a list or array of tuples:

```
In [37]: s.reindex(index[:3])
Out[37]:
first  second
bar    one      -0.175866
       two      -0.387992
baz    one      -1.549540
dtype: float64

In [38]: s.reindex([('foo', 'two'), ('bar', 'one'), ('qux', 'one'), ('baz', 'one')])
Out[38]:
foo  two   -0.399375
bar  one   -0.175866
qux  one   0.432241
baz  one   -1.549540
dtype: float64
```

3.3.2 Advanced indexing with hierarchical index

Syntactically integrating MultiIndex in advanced indexing with `.loc` is a bit challenging, but we've made every effort to do so. In general, MultiIndex keys take the form of tuples. For example, the following works as you would expect:

```
In [39]: df = df.T

In [40]: df
Out[40]:
          A         B         C
first  second
bar    one      -0.950344 -0.360387  0.689151
       two       0.696571 -1.061247 -0.021507
baz    one       0.146563  1.394812 -0.773364
       two       0.270220  0.388240 -2.190632
foo    one       0.441303  0.337071 -2.321281
       two      -0.649521 -0.997727 -2.108470
qux    one      -1.010702 -0.101030 -0.487524
       two      -0.260359 -1.590843  0.232929

In [41]: df.loc[('bar', 'two')]
Out[41]:
A      0.696571
B     -1.061247
C    -0.021507
Name: (bar, two), dtype: float64
```

Note that `df.loc['bar', 'two']` would also work in this example, but this shorthand notation can lead to ambiguity in general.

If you also want to index a specific column with `.loc`, you must use a tuple like this:

```
In [42]: df.loc[('bar', 'two'), 'A']
Out[42]: 0.6965714489781875
```

You don't have to specify all levels of the MultiIndex by passing only the first elements of the tuple. For example, you can use "partial" indexing to get all elements with bar in the first level as follows:

```
df.loc['bar']
```

This is a shortcut for the slightly more verbose notation `df.loc[('bar',),]` (equivalent to `df.loc['bar',]` in this example).

"Partial" slicing also works quite nicely.

```
In [43]: df.loc['baz':'foo']
Out[43]:
          A           B           C
first second
baz   one    0.146563  1.394812 -0.773364
      two    0.270220  0.388240 -2.190632
foo   one    0.441303  0.337071 -2.321281
      two   -0.649521 -0.997727 -2.108470
```

You can slice with a 'range' of values, by providing a slice of tuples.

```
In [44]: df.loc[('baz', 'two'):('qux', 'one')]
Out[44]:
          A           B           C
first second
baz   two    0.270220  0.388240 -2.190632
foo   one    0.441303  0.337071 -2.321281
      two   -0.649521 -0.997727 -2.108470
qux   one   -1.010702 -0.101030 -0.487524

In [45]: df.loc[('baz', 'two'):'foo']
Out[45]:
          A           B           C
first second
baz   two    0.270220  0.388240 -2.190632
foo   one    0.441303  0.337071 -2.321281
      two   -0.649521 -0.997727 -2.108470
```

Passing a list of labels or tuples works similar to reindexing:

```
In [46]: df.loc[[('bar', 'two'), ('qux', 'one')]]
Out[46]:
          A           B           C
first second
bar   two    0.696571 -1.061247 -0.021507
qux   one   -1.010702 -0.101030 -0.487524
```

Note: It is important to note that tuples and lists are not treated identically in pandas when it comes to indexing. Whereas a tuple is interpreted as one multi-level key, a list is used to specify several keys. Or in other words, tuples go horizontally (traversing levels), lists go vertically (scanning levels).

Importantly, a list of tuples indexes several complete MultiIndex keys, whereas a tuple of lists refer to several values within a level:

```
In [47]: s = pd.Series([1, 2, 3, 4, 5, 6],
....:                   index=pd.MultiIndex.from_product([["A", "B"], ["c", "d", "e"]]))
....:

In [48]: s.loc[[("A", "c"), ("B", "d")]] # list of tuples
Out[48]:
A c    1
B d    5
dtype: int64

In [49]: s.loc[[("A", "B"), ["c", "d"]]] # tuple of lists
Out[49]:
A c    1
    d    2
B c    4
    d    5
dtype: int64
```

Using slicers

You can slice a MultiIndex by providing multiple indexers.

You can provide any of the selectors as if you are indexing by label, see [Selection by Label](#), including slices, lists of labels, labels, and boolean indexers.

You can use `slice(None)` to select all the contents of *that* level. You do not need to specify all the *deeper* levels, they will be implied as `slice(None)`.

As usual, **both sides** of the slicers are included as this is label indexing.

Warning: You should specify all axes in the `.loc` specifier, meaning the indexer for the `index` and for the `columns`. There are some ambiguous cases where the passed indexer could be mis-interpreted as indexing *both* axes, rather than into say the MultiIndex for the rows.

You should do this:

```
df.loc[(slice('A1', 'A3'), ...), :] # noqa: E999
```

You should **not** do this:

```
df.loc[(slice('A1', 'A3'), ...)] # noqa: E999
```

```
In [50]: def mklbl(prefix, n):
....:     return ["%s%s" % (prefix, i) for i in range(n)]
....:

In [51]: miindex = pd.MultiIndex.from_product([mklbl('A', 4),
....:                                              mklbl('B', 2),
....:                                              mklbl('C', 4),
....:                                              mklbl('D', 2)])
....:

In [52]: micolumns = pd.MultiIndex.from_tuples([('a', 'foo'), ('a', 'bar'),
....:                                              ('b', 'foo'), ('b', 'bah')],
....:                                              names=['lvl0', 'lvl1']))
```

(continues on next page)

(continued from previous page)

```
....:

In [53]: dfmi = pd.DataFrame(np.arange(len(miindex) * len(micolumns))
....:                         .reshape((len(miindex), len(micolumns))),
....:                         index=miindex,
....:                         columns=micolumns).sort_index().sort_index(axis=1)
....:

In [54]: dfmi
Out[54]:
lv10      a      b
lv11    bar  foo  bah  foo
A0 B0 C0 D0   1   0   3   2
          D1   5   4   7   6
          C1 D0   9   8  11  10

          D1 245 244 247 246
          C3 D0 249 248 251 250
          D1 253 252 255 254

[64 rows x 4 columns]
```

Basic MultiIndex slicing using slices, lists, and labels.

```
In [55]: dfmi.loc[(slice('A1', 'A3'), slice(None), ['C1', 'C3']), :]
Out[55]:
lv10      a      b
lv11    bar  foo  bah  foo
A1 B0 C1 D0  73   72   75   74
          D1  77   76   79   78
          C3 D0  89   88   91   90
          D1  93   92   95   94
          B1 C1 D0 105  104  107  106
          D1 109  108  111  110
          C3 D0 121  120  123  122
          D1 125  124  127  126
A2 B0 C1 D0 137  136  139  138
          D1 141  140  143  142
          C3 D0 153  152  155  154
          D1 157  156  159  158
          B1 C1 D0 169  168  171  170
          D1 173  172  175  174
          C3 D0 185  184  187  186
          D1 189  188  191  190
A3 B0 C1 D0 201  200  203  202
          D1 205  204  207  206
          C3 D0 217  216  219  218
          D1 221  220  223  222
          B1 C1 D0 233  232  235  234
          D1 237  236  239  238
          C3 D0 249  248  251  250
          D1 253  252  255  254
```

You can use `pandas.IndexSlice` to facilitate a more natural syntax using `:`, rather than using `slice(None)`.

```
In [56]: idx = pd.IndexSlice

In [57]: dfmi.loc[idx[:, :, ['C1', 'C3']], idx[:, 'foo']]
Out[57]:
    lvl0      a      b
    lvl1      foo   foo
A0 B0 C1 D0    8    10
          D1   12   14
          C3 D0   24   26
          D1   28   30
B1 C1 D0   40   42
          D1   44   46
          C3 D0   56   58
          D1   60   62
A1 B0 C1 D0   72   74
          D1   76   78
          C3 D0   88   90
          D1   92   94
B1 C1 D0  104  106
          D1  108  110
          C3 D0  120  122
          D1  124  126
A2 B0 C1 D0  136  138
          D1  140  142
          C3 D0  152  154
          D1  156  158
B1 C1 D0  168  170
          D1  172  174
          C3 D0  184  186
          D1  188  190
A3 B0 C1 D0  200  202
          D1  204  206
          C3 D0  216  218
          D1  220  222
B1 C1 D0  232  234
          D1  236  238
          C3 D0  248  250
          D1  252  254
```

It is possible to perform quite complicated selections using this method on multiple axes at the same time.

```
In [58]: dfmi.loc['A1', (slice(None), 'foo')]
Out[58]:
    lvl0      a      b
    lvl1      foo   foo
B0 C0 D0   64   66
          D1   68   70
C1 D0   72   74
          D1   76   78
C2 D0   80   82
          D1   84   86
C3 D0   88   90
          D1   92   94
B1 C0 D0   96   98
          D1  100  102
C1 D0  104  106
```

(continues on next page)

(continued from previous page)

B1 C1 D0 232  234
          D1  236  238
          C3 D0 248  250
          D1  252  254
```

Using a boolean indexer you can provide selection related to the *values*.

```
In [60]: mask = dfmi[('a', 'foo')] > 200

In [61]: dfmi.loc[idx[mask, :, ['C1', 'C3']], idx[:, 'foo']]
Out[61]:
lvl0      a      b
lvl1      foo    foo
A3 B0 C1 D1 204 206
          C3 D0 216 218
          D1 220 222
B1 C1 D0 232 234
          D1 236 238
          C3 D0 248 250
```

(continues on next page)

(continued from previous page)

D1 252 254

You can also specify the `axis` argument to `.loc` to interpret the passed slicers on a single axis.

```
In [62]: dfmi.loc(axis=0)[:, :, ['C1', 'C3']]
```

```
Out[62]:
```

		a	b	
lvl0	bar	foo	bah	foo
A0 B0 C1 D0	9	8	11	10
	D1	13	12	15
	C3	25	24	27
	D1	29	28	31
B1 C1 D0	41	40	43	42
	D1	45	44	47
	C3	57	56	59
	D1	61	60	63
A1 B0 C1 D0	73	72	75	74
	D1	77	76	79
	C3	89	88	91
	D1	93	92	95
B1 C1 D0	105	104	107	106
	D1	109	108	111
	C3	121	120	123
	D1	125	124	127
A2 B0 C1 D0	137	136	139	138
	D1	141	140	143
	C3	153	152	155
	D1	157	156	159
B1 C1 D0	169	168	171	170
	D1	173	172	175
	C3	185	184	187
	D1	189	188	191
A3 B0 C1 D0	201	200	203	202
	D1	205	204	207
	C3	217	216	219
	D1	221	220	223
B1 C1 D0	233	232	235	234
	D1	237	236	239
	C3	249	248	251
	D1	253	252	255

Furthermore, you can *set* the values using the following methods.

```
In [63]: df2 = dfmi.copy()
```

```
In [64]: df2.loc(axis=0)[:, :, ['C1', 'C3']] = -10
```

```
Out[65]:
```

		a	b	
lvl0	bar	foo	bah	foo
A0 B0 C0 D0	1	0	3	2
	D1	5	4	7
	C1	-10	-10	-10
	D1	-10	-10	-10
	C2	17	16	19
	D1	18	17	18
...

(continues on next page)

(continued from previous page)

```
A3  B1  C1  D1   -10   -10   -10   -10
    C2  D0   241   240   243   242
        D1   245   244   247   246
    C3  D0   -10   -10   -10   -10
        D1   -10   -10   -10   -10
```

[64 rows x 4 columns]

You can use a right-hand-side of an alignable object as well.

```
In [66]: df2 = dfmi.copy()
```

```
In [67]: df2.loc[idx[:, :, ['C1', 'C3']], :] = df2 * 1000
```

```
In [68]: df2
```

```
Out[68]:
```

		a	b				
lvl0							
lvl1		bar	foo				
A0	B0	C0	D0	1	0	3	2
			D1	5	4	7	6
		C1	D0	9000	8000	11000	10000
			D1	13000	12000	15000	14000
		C2	D0	17	16	19	18
...
A3	B1	C1	D1	237000	236000	239000	238000
		C2	D0	241	240	243	242
			D1	245	244	247	246
		C3	D0	249000	248000	251000	250000
			D1	253000	252000	255000	254000

[64 rows x 4 columns]

Cross-section

The `xs()` method of `DataFrame` additionally takes a `level` argument to make selecting data at a particular level of a `MultiIndex` easier.

```
In [69]: df
```

```
Out[69]:
```

		A	B	C
first	second			
bar	one	-0.950344	-0.360387	0.689151
	two	0.696571	-1.061247	-0.021507
baz	one	0.146563	1.394812	-0.773364
	two	0.270220	0.388240	-2.190632
foo	one	0.441303	0.337071	-2.321281
	two	-0.649521	-0.997727	-2.108470
qux	one	-1.010702	-0.101030	-0.487524
	two	-0.260359	-1.590843	0.232929

```
In [70]: df.xs('one', level='second')
```

```
Out[70]:
```

	A	B	C
first			
bar	-0.950344	-0.360387	0.689151

(continues on next page)

(continued from previous page)

```
baz    0.146563  1.394812 -0.773364
foo    0.441303  0.337071 -2.321281
qux   -1.010702 -0.101030 -0.487524
```

```
# using the slicers
In [71]: df.loc[(slice(None), 'one'), :]
Out[71]:
          A         B         C
first second
bar    one    -0.950344 -0.360387  0.689151
baz    one     0.146563  1.394812 -0.773364
foo    one     0.441303  0.337071 -2.321281
qux   one    -1.010702 -0.101030 -0.487524
```

You can also select on the columns with `xs`, by providing the `axis` argument.

```
In [72]: df = df.T

In [73]: df.xs('one', level='second', axis=1)
Out[73]:
          first      bar      baz      foo      qux
A    -0.950344  0.146563  0.441303 -1.010702
B    -0.360387  1.394812  0.337071 -0.101030
C     0.689151 -0.773364 -2.321281 -0.487524
```

```
# using the slicers
In [74]: df.loc[:, (slice(None), 'one')]
Out[74]:
          first      bar      baz      foo      qux
first      bar      baz      foo      qux
second     one      one      one      one
A    -0.950344  0.146563  0.441303 -1.010702
B    -0.360387  1.394812  0.337071 -0.101030
C     0.689151 -0.773364 -2.321281 -0.487524
```

`xs` also allows selection with multiple keys.

```
In [75]: df.xs(('one', 'bar'), level=('second', 'first'), axis=1)
Out[75]:
          first      bar
          second     one
          A      -0.950344
          B      -0.360387
          C       0.689151
```

```
# using the slicers
In [76]: df.loc[:, ('bar', 'one')]
Out[76]:
          A      -0.950344
          B      -0.360387
          C       0.689151
Name: (bar, one), dtype: float64
```

You can pass `drop_level=False` to `xs` to retain the level that was selected.

```
In [77]: df.xs('one', level='second', axis=1, drop_level=False)
Out[77]:
first      bar      baz      foo      qux
second    one     one     one     one
A       -0.950344  0.146563  0.441303 -1.010702
B       -0.360387  1.394812  0.337071 -0.101030
C        0.689151 -0.773364 -2.321281 -0.487524
```

Compare the above with the result using `drop_level=True` (the default value).

```
In [78]: df.xs('one', level='second', axis=1, drop_level=True)
Out[78]:
first      bar      baz      foo      qux
A       -0.950344  0.146563  0.441303 -1.010702
B       -0.360387  1.394812  0.337071 -0.101030
C        0.689151 -0.773364 -2.321281 -0.487524
```

Advanced reindexing and alignment

Using the parameter `level` in the `reindex()` and `align()` methods of pandas objects is useful to broadcast values across a level. For instance:

```
In [79]: midx = pd.MultiIndex(levels=[[ 'zero', 'one'], [ 'x', 'y']],
....:                         codes=[[1, 1, 0, 0], [1, 0, 1, 0]])
....:

In [80]: df = pd.DataFrame(np.random.randn(4, 2), index=midx)

In [81]: df
Out[81]:
          0      1
one   y  2.685502 -1.607027
      x -0.657762 -0.258372
zero  y -1.916579  1.276699
      x  1.028099 -0.248804

In [82]: df2 = df.mean(level=0)

In [83]: df2
Out[83]:
          0      1
one    1.01387 -0.932700
zero  -0.44424  0.513948

In [84]: df2.reindex(df.index, level=0)
Out[84]:
          0      1
one   y  1.01387 -0.932700
      x  1.01387 -0.932700
zero  y -0.44424  0.513948
      x -0.44424  0.513948

# aligning
In [85]: df_aligned, df2_aligned = df.align(df2, level=0)

In [86]: df_aligned
```

(continues on next page)

(continued from previous page)

Out [86] :

	0	1
one	y	2.685502 -1.607027
	x	-0.657762 -0.258372
zero	y	-1.916579 1.276699
	x	1.028099 -0.248804

In [87] : df2_aligned**Out [87] :**

	0	1
one	y	1.01387 -0.932700
	x	1.01387 -0.932700
zero	y	-0.44424 0.513948
	x	-0.44424 0.513948

Swapping levels with swaplevel

The `swaplevel()` method can switch the order of two levels:

In [88] : df[:5]**Out [88] :**

	0	1
one	y	2.685502 -1.607027
	x	-0.657762 -0.258372
zero	y	-1.916579 1.276699
	x	1.028099 -0.248804

In [89] : df[:5].swaplevel(0, 1, axis=0)**Out [89] :**

	0	1
y	one	2.685502 -1.607027
x	one	-0.657762 -0.258372
y	zero	-1.916579 1.276699
x	zero	1.028099 -0.248804

Reordering levels with reorder_levels

The `reorder_levels()` method generalizes the `swaplevel` method, allowing you to permute the hierarchical index levels in one step:

In [90] : df[:5].reorder_levels([1, 0], axis=0)**Out [90] :**

	0	1
y	one	2.685502 -1.607027
x	one	-0.657762 -0.258372
y	zero	-1.916579 1.276699
x	zero	1.028099 -0.248804

Renaming names of an Index or MultiIndex

The `rename()` method is used to rename the labels of a `MultiIndex`, and is typically used to rename the columns of a `DataFrame`. The `columns` argument of `rename` allows a dictionary to be specified that includes only the columns you wish to rename.

```
In [91]: df.rename(columns={0: "col0", 1: "col1"})
Out[91]:
      col0      col1
one   y  2.685502 -1.607027
      x -0.657762 -0.258372
zero  y -1.916579  1.276699
      x  1.028099 -0.248804
```

This method can also be used to rename specific labels of the main index of the `DataFrame`.

```
In [92]: df.rename(index={"one": "two", "y": "z"})
Out[92]:
      0      1
two  z  2.685502 -1.607027
      x -0.657762 -0.258372
zero z -1.916579  1.276699
      x  1.028099 -0.248804
```

The `rename_axis()` method is used to rename the name of a `Index` or `MultiIndex`. In particular, the names of the levels of a `MultiIndex` can be specified, which is useful if `reset_index()` is later used to move the values from the `MultiIndex` to a column.

```
In [93]: df.rename_axis(index=['abc', 'def'])
Out[93]:
      0      1
abc  def
one  y  2.685502 -1.607027
      x -0.657762 -0.258372
zero y -1.916579  1.276699
      x  1.028099 -0.248804
```

Note that the columns of a `DataFrame` are an index, so that using `rename_axis` with the `columns` argument will change the name of that index.

```
In [94]: df.rename_axis(columns="Cols").columns
Out[94]: RangeIndex(start=0, stop=2, step=1, name='Cols')
```

Both `rename` and `rename_axis` support specifying a dictionary, `Series` or a mapping function to map labels/names to new values.

When working with an `Index` object directly, rather than via a `DataFrame`, `Index.set_names()` can be used to change the names.

```
In [95]: mi = pd.MultiIndex.from_product([[1, 2], ['a', 'b']], names=['x', 'y'])

In [96]: mi.names
Out[96]: FrozenList(['x', 'y'])

In [97]: mi2 = mi.rename("new name", level=0)

In [98]: mi2
```

(continues on next page)

(continued from previous page)

Out[98]:

```
MultiIndex([(1, 'a'),
            (1, 'b'),
            (2, 'a'),
            (2, 'b')],  
names=['new name', 'y'])
```

You cannot set the names of the MultiIndex via a level.

```
In [99]: mi.levels[0].name = "name via level"  
-----  
RuntimeError Traceback (most recent call last)  
<ipython-input-99-35d32a9a5218> in <module>  
----> 1 mi.levels[0].name = "name via level"  
  
/pandas/pandas/core/indexes/base.py in name(self, value)  
    1189         # Used in MultiIndex.levels to avoid silently ignoring name  
    --> 1190             raise RuntimeError(  
-> 1191                 "Cannot set name on a level of a MultiIndex. Use "  
    1192                 "'MultiIndex.set_names' instead."  
    1193             )  
  
RuntimeError: Cannot set name on a level of a MultiIndex. Use 'MultiIndex.set_names'  
--> instead.
```

Use `Index.set_names()` instead.

3.3.3 Sorting a MultiIndex

For MultiIndex-ed objects to be indexed and sliced effectively, they need to be sorted. As with any index, you can use `sort_index()`.

```
In [100]: import random  
  
In [101]: random.shuffle(tuples)  
  
In [102]: s = pd.Series(np.random.randn(8), index=pd.MultiIndex.from_tuples(tuples))  
  
In [103]: s  
Out[103]:  
qux one   -0.586992  
foo one   -0.077109  
qux two   -0.969780  
baz two    0.033576  
bar one   -0.032224  
foo two   -1.747777  
baz one    0.131568  
bar two    0.838255  
dtype: float64  
  
In [104]: s.sort_index()  
Out[104]:  
bar one   -0.032224  
two      0.838255
```

(continues on next page)

(continued from previous page)

```
baz  one    0.131568
     two    0.033576
foo  one   -0.077109
     two   -1.747777
qux  one   -0.586992
     two   -0.969780
dtype: float64
```

In [105]: `s.sort_index(level=0)`

Out[105]:

```
bar  one   -0.032224
     two   0.838255
baz  one    0.131568
     two    0.033576
foo  one   -0.077109
     two   -1.747777
qux  one   -0.586992
     two   -0.969780
dtype: float64
```

In [106]: `s.sort_index(level=1)`

Out[106]:

```
bar  one   -0.032224
baz  one    0.131568
foo  one   -0.077109
qux  one   -0.586992
bar  two   0.838255
baz  two    0.033576
foo  two   -1.747777
qux  two   -0.969780
dtype: float64
```

You may also pass a level name to `sort_index` if the MultiIndex levels are named.

In [107]: `s.index.set_names(['L1', 'L2'], inplace=True)`

In [108]: `s.sort_index(level='L1')`

Out[108]:

```
L1    L2
bar  one   -0.032224
     two   0.838255
baz  one    0.131568
     two    0.033576
foo  one   -0.077109
     two   -1.747777
qux  one   -0.586992
     two   -0.969780
dtype: float64
```

In [109]: `s.sort_index(level='L2')`

Out[109]:

```
L1    L2
bar  one   -0.032224
baz  one    0.131568
foo  one   -0.077109
qux  one   -0.586992
bar  two   0.838255
```

(continues on next page)

(continued from previous page)

```
baz  two    0.033576
foo  two   -1.747777
qux  two   -0.969780
dtype: float64
```

On higher dimensional objects, you can sort any of the other axes by level if they have a MultiIndex:

```
In [110]: df.T.sort_index(level=1, axis=1)
Out[110]:
      one      zero      one      zero
      x          x          y          y
0 -0.657762  1.028099  2.685502 -1.916579
1 -0.258372 -0.248804 -1.607027  1.276699
```

Indexing will work even if the data are not sorted, but will be rather inefficient (and show a `PerformanceWarning`). It will also return a copy of the data rather than a view:

```
In [111]: dfm = pd.DataFrame({'jim': [0, 0, 1, 1],
.....:                      'joe': ['x', 'x', 'z', 'y'],
.....:                      'jolie': np.random.rand(4)},
.....:

In [112]: dfm = dfm.set_index(['jim', 'joe'])

In [113]: dfm
Out[113]:
           jolie
jim joe
0     x    0.905151
      x    0.129110
1     z    0.395024
      y    0.689641
```

```
In [4]: dfm.loc[(1, 'z')]
PerformanceWarning: indexing past lexsort depth may impact performance.

Out[4]:
           jolie
jim joe
1     z    0.64094
```

Furthermore, if you try to index something that is not fully lexsorted, this can raise:

```
In [5]: dfm.loc[(0, 'y'): (1, 'z')]
UnsortedIndexError: 'Key length (2) was greater than MultiIndex lexsort depth (1)'
```

The `is_lexsorted()` method on a MultiIndex shows if the index is sorted, and the `lexsort_depth` property returns the sort depth:

```
In [114]: dfm.index.is_lexsorted()
Out[114]: False

In [115]: dfm.index.lexsort_depth
Out[115]: 1
```

```
In [116]: dfm = dfm.sort_index()

In [117]: dfm
Out[117]:
          jolie
jim  joe
0      x    0.905151
      x    0.129110
1      y    0.689641
      z    0.395024

In [118]: dfm.index.is_lexsorted()
Out[118]: True

In [119]: dfm.index.lexsort_depth
Out[119]: 2
```

And now selection works as expected.

```
In [120]: dfm.loc[(0, 'y'):(1, 'z')]
Out[120]:
          jolie
jim  joe
1      y    0.689641
      z    0.395024
```

3.3.4 Take methods

Similar to NumPy ndarrays, pandas Index, Series, and DataFrame also provides the `take()` method that retrieves elements along a given axis at the given indices. The given indices must be either a list or an ndarray of integer index positions. `take` will also accept negative integers as relative positions to the end of the object.

```
In [121]: index = pd.Index(np.random.randint(0, 1000, 10))

In [122]: index
Out[122]: Int64Index([760, 759, 928, 346, 288, 433, 498, 488, 540, 324], dtype='int64
         ')

In [123]: positions = [0, 9, 3]

In [124]: index[positions]
Out[124]: Int64Index([760, 324, 346], dtype='int64')

In [125]: index.take(positions)
Out[125]: Int64Index([760, 324, 346], dtype='int64')

In [126]: ser = pd.Series(np.random.randn(10))

In [127]: ser.iloc[positions]
Out[127]:
0    1.873788
9   -0.369975
3   -1.042033
dtype: float64
```

(continues on next page)

(continued from previous page)

```
In [128]: ser.take(positions)
Out[128]:
0    1.873788
9   -0.369975
3   -1.042033
dtype: float64
```

For DataFrames, the given indices should be a 1d list or ndarray that specifies row or column positions.

```
In [129]: frm = pd.DataFrame(np.random.randn(5, 3))

In [130]: frm.take([1, 4, 3])
Out[130]:
   0      1      2
1 -0.520593 -1.065669 -1.643779
4 -0.136622 -0.335107 -0.292217
3  0.929852  0.195850  1.860922

In [131]: frm.take([0, 2], axis=1)
Out[131]:
   0      2
0  0.307424 -0.997422
1 -0.520593 -1.643779
2  0.501239 -1.377935
3  0.929852  1.860922
4 -0.136622 -0.292217
```

It is important to note that the `take` method on pandas objects are not intended to work on boolean indices and may return unexpected results.

```
In [132]: arr = np.random.randn(10)

In [133]: arr.take([False, False, True, True])
Out[133]: array([ 0.06711491,  0.06711491, -1.85680799, -1.85680799])

In [134]: arr[[0, 1]]
Out[134]: array([ 0.06711491, -1.85680799])

In [135]: ser = pd.Series(np.random.randn(10))

In [136]: ser.take([False, False, True, True])
Out[136]:
0    0.468414
0    0.468414
1   -1.307889
1   -1.307889
dtype: float64

In [137]: ser.iloc[[0, 1]]
Out[137]:
0    0.468414
1   -1.307889
dtype: float64
```

Finally, as a small note on performance, because the `take` method handles a narrower range of inputs, it can offer performance that is a good deal faster than fancy indexing.

```
In [138]: arr = np.random.randn(10000, 5)

In [139]: indexer = np.arange(10000)

In [140]: random.shuffle(indexer)

In [141]: %timeit arr[indexer]
.....: %timeit arr.take(indexer, axis=0)
.....:
155 us +- 10.1 us per loop (mean +- std. dev. of 7 runs, 10000 loops each)
51.7 us +- 1.69 us per loop (mean +- std. dev. of 7 runs, 10000 loops each)
```

```
In [142]: ser = pd.Series(arr[:, 0])

In [143]: %timeit ser.iloc[indexer]
.....: %timeit ser.take(indexer)
.....:
150 us +- 11.5 us per loop (mean +- std. dev. of 7 runs, 10000 loops each)
143 us +- 13.9 us per loop (mean +- std. dev. of 7 runs, 10000 loops each)
```

3.3.5 Index types

We have discussed MultiIndex in the previous sections pretty extensively. Documentation about DatetimeIndex and PeriodIndex are shown [here](#), and documentation about TimedeltaIndex is found [here](#).

In the following sub-sections we will highlight some other index types.

CategoricalIndex

CategoricalIndex is a type of index that is useful for supporting indexing with duplicates. This is a container around a Categorical and allows efficient indexing and storage of an index with a large number of duplicated elements.

```
In [144]: from pandas.api.types import CategoricalDtype

In [145]: df = pd.DataFrame({'A': np.arange(6),
.....:                  'B': list('aabbc')})
.....:

In [146]: df['B'] = df['B'].astype(CategoricalDtype(list('cab')))

In [147]: df
Out[147]:
   A   B
0  0   a
1  1   a
2  2   b
3  3   b
4  4   c
5  5   a

In [148]: df.dtypes
Out[148]:
```

(continues on next page)

(continued from previous page)

```
A      int64
B    category
dtype: object

In [149]: df['B'].cat.categories
Out[149]: Index(['c', 'a', 'b'], dtype='object')
```

Setting the index will create a CategoricalIndex.

```
In [150]: df2 = df.set_index('B')

In [151]: df2.index
Out[151]: CategoricalIndex(['a', 'a', 'b', 'b', 'c', 'a'], categories=['c', 'a', 'b'],
                           ordered=False, name='B', dtype='category')
```

Indexing with `__getitem__`/`.iloc`/`.loc` works similarly to an Index with duplicates. The indexers **must** be in the category or the operation will raise a `KeyError`.

```
In [152]: df2.loc['a']
Out[152]:
A
B
a  0
a  1
a  5
```

The CategoricalIndex is **preserved** after indexing:

```
In [153]: df2.loc['a'].index
Out[153]: CategoricalIndex(['a', 'a', 'a'], categories=['c', 'a', 'b'], ordered=False,
                           name='B', dtype='category')
```

Sorting the index will sort by the order of the categories (recall that we created the index with `CategoricalDtype(list('cab'))`, so the sorted order is cab).

```
In [154]: df2.sort_index()
Out[154]:
A
B
c  4
a  0
a  1
a  5
b  2
b  3
```

Groupby operations on the index will preserve the index nature as well.

```
In [155]: df2.groupby(level=0).sum()
Out[155]:
A
B
c  4
a  6
b  5
```

(continues on next page)

(continued from previous page)

```
In [156]: df2.groupby(level=0).sum().index
Out[156]: CategoricalIndex(['c', 'a', 'b'], categories=['c', 'a', 'b'], ordered=False,
                           name='B', dtype='category')
```

Reindexing operations will return a resulting index based on the type of the passed indexer. Passing a list will return a plain-old Index; indexing with a Categorical will return a CategoricalIndex, indexed according to the categories of the **passed** Categorical dtype. This allows one to arbitrarily index these even with values **not** in the categories, similarly to how you can reindex **any** pandas index.

```
In [157]: df3 = pd.DataFrame({ 'A': np.arange(3),
                               'B': pd.Series(list('abc')).astype('category') })
.....
.....
In [158]: df3 = df3.set_index('B')

↪', dtype='category')

In [1]: pd.concat([df4, df5])
TypeError: categories must match existing categories when appending

```

Int64Index and RangeIndex

`Int64Index` is a fundamental basic index in pandas. This is an immutable array implementing an ordered, sliceable set.

`RangeIndex` is a sub-class of `Int64Index` that provides the default index for all `NDFrame` objects. `RangeIndex` is an optimized version of `Int64Index` that can represent a monotonic ordered set. These are analogous to Python `range` types.

Float64Index

By default a `Float64Index` will be automatically created when passing floating, or mixed-integer-floating values in index creation. This enables a pure label-based slicing paradigm that makes `[]`, `ix`, `loc` for scalar indexing and slicing work exactly the same.

```

In [172]: indexf = pd.Index([1.5, 2, 3, 4.5, 5])
In [173]: indexf
Out[173]: Float64Index([1.5, 2.0, 3.0, 4.5, 5.0], dtype='float64')

In [174]: sf = pd.Series(range(5), index=indexf)

In [175]: sf
Out[175]:
1.5    0
2.0    1
3.0    2
4.5    3
5.0    4
dtype: int64

```

Scalar selection for `[]`, `.loc` will always be label based. An integer will match an equal float index (e.g. 3 is equivalent to 3.0).

```

In [176]: sf[3]
Out[176]: 2

```

(continues on next page)

(continued from previous page)

```
In [177]: sf[3.0]
Out[177]: 2

In [178]: sf.loc[3]
Out[178]: 2

In [179]: sf.loc[3.0]
Out[179]: 2
```

The only positional indexing is via `iloc`.

```
In [180]: sf.iloc[3]
Out[180]: 3
```

A scalar index that is not found will raise a `KeyError`. Slicing is primarily on the values of the index when using `[]`, `ix`, `loc`, and **always** positional when using `iloc`. The exception is when the slice is boolean, in which case it will always be positional.

```
In [181]: sf[2:4]
Out[181]:
2.0    1
3.0    2
dtype: int64

In [182]: sf.loc[2:4]
Out[182]:
2.0    1
3.0    2
dtype: int64

In [183]: sf.iloc[2:4]
Out[183]:
3.0    2
4.5    3
dtype: int64
```

In float indexes, slicing using floats is allowed.

```
In [184]: sf[2.1:4.6]
Out[184]:
3.0    2
4.5    3
dtype: int64

In [185]: sf.loc[2.1:4.6]
Out[185]:
3.0    2
4.5    3
dtype: int64
```

In non-float indexes, slicing using floats will raise a `TypeError`.

```
In [1]: pd.Series(range(5))[3.5]
TypeError: the label [3.5] is not a proper indexer for this index type (Int64Index)
```

(continues on next page)

(continued from previous page)

```
In [1]: pd.Series(range(5))[3.5:4.5]
TypeError: the slice start [3.5] is not a proper indexer for this index type
→ (Int64Index)
```

Here is a typical use-case for using this type of indexing. Imagine that you have a somewhat irregular timedelta-like indexing scheme, but the data is recorded as floats. This could, for example, be millisecond offsets.

```
In [186]: dfir = pd.concat([pd.DataFrame(np.random.randn(5, 2),
.....:                               index=np.arange(5) * 250.0,
.....:                               columns=list('AB')),
.....:                               pd.DataFrame(np.random.randn(6, 2),
.....:                               index=np.arange(4, 10) * 250.1,
.....:                               columns=list('AB'))])
.....:
```

```
In [187]: dfir
Out[187]:
```

	A	B
0.0	0.137460	0.225447
250.0	-0.087652	-0.877716
500.0	-1.134396	-0.010175
750.0	-1.939589	-0.436433
1000.0	-0.736253	-0.372114
1000.4	0.253196	-0.277950
1250.5	-2.015268	-0.352490
1500.6	-0.501003	0.387471
1750.7	1.351617	0.334301
2000.8	1.522577	-0.474427
2250.9	-0.747827	-0.295121

Selection operations then will always work on a value basis, for all selection operators.

```
In [188]: dfir[0:1000.4]
Out[188]:
```

	A	B
0.0	0.137460	0.225447
250.0	-0.087652	-0.877716
500.0	-1.134396	-0.010175
750.0	-1.939589	-0.436433
1000.0	-0.736253	-0.372114
1000.4	0.253196	-0.277950

```
In [189]: dfir.loc[0:1001, 'A']
Out[189]:
```

	A
0.0	0.137460
250.0	-0.087652
500.0	-1.134396
750.0	-1.939589
1000.0	-0.736253
1000.4	0.253196

```
Name: A, dtype: float64
```

```
In [190]: dfir.loc[1000.4]
Out[190]:
```

	A	B
A	0.253196	
B	-0.277950	

```
Name: 1000.4, dtype: float64
```

You could retrieve the first 1 second (1000 ms) of data as such:

```
In [191]: dfir[0:1000]
Out[191]:
      A          B
0.0   0.137460  0.225447
250.0 -0.087652 -0.877716
500.0 -1.134396 -0.010175
750.0 -1.939589 -0.436433
1000.0 -0.736253 -0.372114
```

If you need integer based selection, you should use `iloc`:

```
In [192]: dfir.iloc[0:5]
Out[192]:
      A          B
0.0   0.137460  0.225447
250.0 -0.087652 -0.877716
500.0 -1.134396 -0.010175
750.0 -1.939589 -0.436433
1000.0 -0.736253 -0.372114
```

IntervalIndex

`IntervalIndex` together with its own `dtype`, `IntervalDtype` as well as the `Interval` scalar type, allow first-class support in pandas for interval notation.

The `IntervalIndex` allows some unique indexing and is also used as a return type for the categories in `cut()` and `qcut()`.

Indexing with an IntervalIndex

An `IntervalIndex` can be used in `Series` and in `DataFrame` as the index.

```
In [193]: df = pd.DataFrame({'A': [1, 2, 3, 4]}, 
                           index=pd.IntervalIndex.from_breaks([0, 1, 2, 3, 4]))
.....
.....
In [194]: df
Out[194]:
      A
(0, 1] 1
(1, 2] 2
(2, 3] 3
(3, 4] 4
```

Label based indexing via `.loc` along the edges of an interval works as you would expect, selecting that particular interval.

```
In [195]: df.loc[2]
Out[195]:
A    2
Name: (1, 2], dtype: int64
In [196]: df.loc[[2, 3]]
```

(continues on next page)

(continued from previous page)

Out[196]:

```
A  
(1, 2] 2  
(2, 3] 3
```

If you select a label *contained* within an interval, this will also select the interval.

```
In [197]: df.loc[2.5]  
Out[197]:  
A      3  
Name: (2, 3], dtype: int64  
  
In [198]: df.loc[[2.5, 3.5]]  
Out[198]:  
A  
(2, 3] 3  
(3, 4] 4
```

Selecting using an `Interval` will only return exact matches (starting from pandas 0.25.0).

```
In [199]: df.loc[pd.Interval(1, 2)]  
Out[199]:  
A      2  
Name: (1, 2], dtype: int64
```

Trying to select an `Interval` that is not exactly contained in the `IntervalIndex` will raise a `KeyError`.

```
In [7]: df.loc[pd.Interval(0.5, 2.5)]  
-----  
KeyError: Interval(0.5, 2.5, closed='right')
```

Selecting all `Intervals` that overlap a given `Interval` can be performed using the `overlaps()` method to create a boolean indexer.

```
In [200]: idxr = df.index.overlaps(pd.Interval(0.5, 2.5))  
  
In [201]: idxr  
Out[201]: array([ True,  True,  True, False])  
  
In [202]: df[idxr]  
Out[202]:  
A  
(0, 1] 1  
(1, 2] 2  
(2, 3] 3
```

Binning data with `cut` and `qcut`

`cut()` and `qcut()` both return a `Categorical` object, and the bins they create are stored as an `IntervalIndex` in its `.categories` attribute.

```
In [203]: c = pd.cut(range(4), bins=2)

In [204]: c
Out[204]:
[(-0.003, 1.5], (-0.003, 1.5], (1.5, 3.0], (1.5, 3.0]]
Categories (2, interval[float64]): [(-0.003, 1.5] < (1.5, 3.0]]

In [205]: c.categories
Out[205]:
IntervalIndex([(−0.003, 1.5], (1.5, 3.0]],
               closed='right',
               dtype='interval[float64]')
```

`cut()` also accepts an `IntervalIndex` for its `bins` argument, which enables a useful pandas idiom. First, we call `cut()` with some data and `bins` set to a fixed number, to generate the bins. Then, we pass the values of `.categories` as the `bins` argument in subsequent calls to `cut()`, supplying new data which will be binned into the same bins.

```
In [206]: pd.cut([0, 3, 5, 1], bins=c.categories)
Out[206]:
[(-0.003, 1.5], (1.5, 3.0], NaN, (-0.003, 1.5]]
Categories (2, interval[float64]): [(-0.003, 1.5] < (1.5, 3.0)]
```

Any value which falls outside all bins will be assigned a `NaN` value.

Generating ranges of intervals

If we need intervals on a regular frequency, we can use the `interval_range()` function to create an `IntervalIndex` using various combinations of `start`, `end`, and `periods`. The default frequency for `interval_range` is a 1 for numeric intervals, and calendar day for datetime-like intervals:

```
In [207]: pd.interval_range(start=0, end=5)
Out[207]:
IntervalIndex([(0, 1], (1, 2], (2, 3], (3, 4], (4, 5]),
              closed='right',
              dtype='interval[int64]')

In [208]: pd.interval_range(start=pd.Timestamp('2017-01-01'), periods=4)
Out[208]:
IntervalIndex([(2017-01-01, 2017-01-02], (2017-01-02, 2017-01-03], (2017-01-03, 2017-
              ↪01-04], (2017-01-04, 2017-01-05]],
               closed='right',
               dtype='interval[datetime64[ns]]')

In [209]: pd.interval_range(end=pd.Timedelta('3 days'), periods=3)
Out[209]:
IntervalIndex([(0 days 00:00:00, 1 days 00:00:00], (1 days 00:00:00, 2 days 00:00:00],
              ↪(2 days 00:00:00, 3 days 00:00:00]),
               closed='right',
               dtype='interval[timedelta64[ns]]')
```

The `freq` parameter can be used to specify non-default frequencies, and can utilize a variety of [frequency aliases](#) with datetime-like intervals:

```
In [210]: pd.interval_range(start=0, periods=5, freq=1.5)
Out[210]:
IntervalIndex([(0.0, 1.5], (1.5, 3.0], (3.0, 4.5], (4.5, 6.0], (6.0, 7.5]),
              closed='right',
              dtype='interval[float64]')

In [211]: pd.interval_range(start=pd.Timestamp('2017-01-01'), periods=4, freq='W')
Out[211]:
IntervalIndex([(2017-01-01, 2017-01-08], (2017-01-08, 2017-01-15], (2017-01-15, 2017-01-22],
              (2017-01-22, 2017-01-29]],
              closed='right',
              dtype='interval[datetime64[ns]]')

In [212]: pd.interval_range(start=pd.Timedelta('0 days'), periods=3, freq='9H')
Out[212]:
IntervalIndex([(0 days 00:00:00, 0 days 09:00:00], (0 days 09:00:00, 0 days 18:00:00],
              (0 days 18:00:00, 1 days 03:00:00]],
              closed='right',
              dtype='interval[timedelta64[ns]]')
```

Additionally, the `closed` parameter can be used to specify which side(s) the intervals are closed on. Intervals are closed on the right side by default.

```
In [213]: pd.interval_range(start=0, end=4, closed='both')
Out[213]:
IntervalIndex([(0, 1], (1, 2], (2, 3], (3, 4]),
              closed='both',
              dtype='interval[int64]')

In [214]: pd.interval_range(start=0, end=4, closed='neither')
Out[214]:
IntervalIndex([(0, 1), (1, 2), (2, 3), (3, 4)],
              closed='neither',
              dtype='interval[int64]')
```

New in version 0.23.0.

Specifying `start`, `end`, and `periods` will generate a range of evenly spaced intervals from `start` to `end` inclusively, with `periods` number of elements in the resulting `IntervalIndex`:

```
In [215]: pd.interval_range(start=0, end=6, periods=4)
Out[215]:
IntervalIndex([(0.0, 1.5], (1.5, 3.0], (3.0, 4.5], (4.5, 6.0]),
              closed='right',
              dtype='interval[float64]')

In [216]: pd.interval_range(pd.Timestamp('2018-01-01'),
.....:                  pd.Timestamp('2018-02-28'), periods=3)
.....:
Out[216]:
IntervalIndex([(2018-01-01, 2018-01-20 08:00:00], (2018-01-20 08:00:00, 2018-02-08 16:00:00],
              (2018-02-08 16:00:00, 2018-02-28]],
              closed='right',
              dtype='interval[datetime64[ns]]')
```

3.3.6 Miscellaneous indexing FAQ

Integer indexing

Label-based indexing with integer axis labels is a thorny topic. It has been discussed heavily on mailing lists and among various members of the scientific Python community. In pandas, our general viewpoint is that labels matter more than integer locations. Therefore, with an integer axis index *only* label-based indexing is possible with the standard tools like `.loc`. The following code will generate exceptions:

```
In [217]: s = pd.Series(range(5))

In [218]: s[-1]
-----
KeyError Traceback (most recent call last)
<ipython-input-218-76c3dce40054> in <module>

KeyError: -1

In [219]: df = pd.DataFrame(np.random.randn(5, 4))

In [220]: df
Out[220]:
   0         1         2         3
0 -0.673682  0.614468 -0.854893  0.625250
1 -1.305915 -1.323911 -1.178487  0.187278
2 -0.691704 -0.068578 -1.292877 -0.350397
3 -0.521565 -1.340581 -1.012930 -1.100162
4 -0.109009 -0.494863  1.374200  0.918760
```

(continues on next page)

(continued from previous page)

```
In [221]: df.loc[-2:]
Out[221]:
   0         1         2         3
0 -0.673682  0.614468 -0.854893  0.625250
1 -1.305915 -1.323911 -1.178487  0.187278
2 -0.691704 -0.068578 -1.292877 -0.350397
3 -0.521565 -1.340581 -1.012930 -1.100162
4 -0.109009 -0.494863  1.374200  0.918760
```

This deliberate decision was made to prevent ambiguities and subtle bugs (many users reported finding bugs when the API change was made to stop “falling back” on position-based indexing).

Non-monotonic indexes require exact matches

If the index of a Series or DataFrame is monotonically increasing or decreasing, then the bounds of a label-based slice can be outside the range of the index, much like slice indexing a normal Python list. Monotonicity of an index can be tested with the `is_monotonic_increasing()` and `is_monotonic_decreasing()` attributes.

```
In [222]: df = pd.DataFrame(index=[2, 3, 3, 4, 5], columns=['data'],
                           data=list(range(5)))
In [223]: df.index.is_monotonic_increasing
Out[223]: True

# no rows 0 or 1, but still returns rows 2, 3 (both of them), and 4:
In [224]: df.loc[0:4, :]
Out[224]:
   data
2      0
3      1
3      2
4      3

# slice is outside the index, so empty DataFrame is returned
In [225]: df.loc[13:15, :]
Out[225]:
Empty DataFrame
Columns: [data]
Index: []
```

On the other hand, if the index is not monotonic, then both slice bounds must be *unique* members of the index.

```
In [226]: df = pd.DataFrame(index=[2, 3, 1, 4, 3, 5],
                           ....,
                           columns=['data'], data=list(range(6)))
.....
In [227]: df.index.is_monotonic_increasing
Out[227]: False

# OK because 2 and 4 are in the index
In [228]: df.loc[2:4, :]
Out[228]:
   data
2      0
3      1
```

(continues on next page)

(continued from previous page)

```
1      2  
4      3
```

```
# 0 is not in the index  
In [9]: df.loc[0:4, :]  
KeyError: 0  
  
# 3 is not a unique label  
In [11]: df.loc[2:3, :]  
KeyError: 'Cannot get right slice bound for non-unique label: 3'
```

`Index.is_monotonic_increasing` and `Index.is_monotonic_decreasing` only check that an index is weakly monotonic. To check for strict monotonicity, you can combine one of those with the `is_unique()` attribute.

```
In [229]: weakly_monotonic = pd.Index(['a', 'b', 'c', 'c'])  
  
In [230]: weakly_monotonic  
Out[230]: Index(['a', 'b', 'c', 'c'], dtype='object')  
  
In [231]: weakly_monotonic.is_monotonic_increasing  
Out[231]: True  
  
In [232]: weakly_monotonic.is_monotonic_increasing & weakly_monotonic.is_unique  
Out[232]: False
```

Endpoints are inclusive

Compared with standard Python sequence slicing in which the slice endpoint is not inclusive, label-based slicing in pandas **is inclusive**. The primary reason for this is that it is often not possible to easily determine the “successor” or next element after a particular label in an index. For example, consider the following Series:

```
In [233]: s = pd.Series(np.random.randn(6), index=list('abcdef'))  
  
In [234]: s  
Out[234]:  
a    0.065578  
b    0.380583  
c    1.678224  
d   -1.922895  
e    0.526141  
f   -0.620716  
dtype: float64
```

Suppose we wished to slice from `c` to `e`, using integers this would be accomplished as such:

```
In [235]: s[2:5]  
Out[235]:  
c    1.678224  
d   -1.922895  
e    0.526141  
dtype: float64
```

However, if you only had `c` and `e`, determining the next element in the index can be somewhat complicated. For example, the following does not work:

```
s.loc['c':'e' + 1]
```

A very common use case is to limit a time series to start and end at two specific dates. To enable this, we made the design choice to make label-based slicing include both endpoints:

```
In [236]: s.loc['c':'e']
Out[236]:
c    1.678224
d   -1.922895
e    0.526141
dtype: float64
```

This is most definitely a “practicality beats purity” sort of thing, but it is something to watch out for if you expect label-based slicing to behave exactly in the way that standard Python integer slicing works.

Indexing potentially changes underlying Series dtype

The different indexing operation can potentially change the dtype of a Series.

```
In [237]: series1 = pd.Series([1, 2, 3])
In [238]: series1.dtype
Out[238]: dtype('int64')

In [239]: res = series1.reindex([0, 4])
In [240]: res.dtype
Out[240]: dtype('float64')

In [241]: res
Out[241]:
0    1.0
4    NaN
dtype: float64
```

```
In [242]: series2 = pd.Series([True])
In [243]: series2.dtype
Out[243]: dtype('bool')

In [244]: res = series2.reindex_like(series1)
In [245]: res.dtype
Out[245]: dtype('O')

In [246]: res
Out[246]:
0    True
1    NaN
2    NaN
dtype: object
```

This is because the (re)indexing operations above silently inserts NaNs and the dtype changes accordingly. This can cause some issues when using numpy ufuncs such as `numpy.logical_and`.

See the [this old issue](#) for a more detailed discussion. {{ header }}

3.4 Merge, join, and concatenate

pandas provides various facilities for easily combining together Series or DataFrame with various kinds of set logic for the indexes and relational algebra functionality in the case of join / merge-type operations.

3.4.1 Concatenating objects

The `concat()` function (in the main pandas namespace) does all of the heavy lifting of performing concatenation operations along an axis while performing optional set logic (union or intersection) of the indexes (if any) on the other axes. Note that I say “if any” because there is only a single possible axis of concatenation for Series.

Before diving into all of the details of `concat` and what it can do, here is a simple example:

```
In [1]: df1 = pd.DataFrame({'A': ['A0', 'A1', 'A2', 'A3'],
....:                      'B': ['B0', 'B1', 'B2', 'B3'],
....:                      'C': ['C0', 'C1', 'C2', 'C3'],
....:                      'D': ['D0', 'D1', 'D2', 'D3']},
....:                     index=[0, 1, 2, 3])
....:

In [2]: df2 = pd.DataFrame({'A': ['A4', 'A5', 'A6', 'A7'],
....:                      'B': ['B4', 'B5', 'B6', 'B7'],
....:                      'C': ['C4', 'C5', 'C6', 'C7'],
....:                      'D': ['D4', 'D5', 'D6', 'D7']},
....:                     index=[4, 5, 6, 7])
....:

In [3]: df3 = pd.DataFrame({'A': ['A8', 'A9', 'A10', 'A11'],
....:                      'B': ['B8', 'B9', 'B10', 'B11'],
....:                      'C': ['C8', 'C9', 'C10', 'C11'],
....:                      'D': ['D8', 'D9', 'D10', 'D11']},
....:                     index=[8, 9, 10, 11])
....:

In [4]: frames = [df1, df2, df3]

In [5]: result = pd.concat(frames)
```

df1				Result				
	A	B	C	D	A	B	C	D
0	A0	B0	C0	D0				
1	A1	B1	C1	D1				
2	A2	B2	C2	D2				
3	A3	B3	C3	D3				

df2				Result				
	A	B	C	D	A	B	C	D
4	A4	B4	C4	D4				
5	A5	B5	C5	D5				
6	A6	B6	C6	D6				
7	A7	B7	C7	D7				

df3				Result				
	A	B	C	D	A	B	C	D
8	A8	B8	C8	D8				
9	A9	B9	C9	D9				
10	A10	B10	C10	D10				
11	A11	B11	C11	D11				

Like its sibling function on ndarrays, `numpy.concatenate`, `pandas.concat` takes a list or dict of homogeneously-typed objects and concatenates them with some configurable handling of “what to do with the other axes”:

```
pd.concat(objs, axis=0, join='outer', ignore_index=False, keys=None,
          levels=None, names=None, verify_integrity=False, copy=True)
```

- `objs`: a sequence or mapping of Series or DataFrame objects. If a dict is passed, the sorted keys will be used as the `keys` argument, unless it is passed, in which case the values will be selected (see below). Any None objects will be dropped silently unless they are all None in which case a ValueError will be raised.
- `axis`: {0, 1, ...}, default 0. The axis to concatenate along.
- `join`: {'inner', 'outer'}, default 'outer'. How to handle indexes on other axis(es). Outer for union and inner for intersection.
- `ignore_index`: boolean, default False. If True, do not use the index values on the concatenation axis. The resulting axis will be labeled 0, ..., n - 1. This is useful if you are concatenating objects where the concatenation axis does not have meaningful indexing information. Note the index values on the other axes are still respected in the join.
- `keys`: sequence, default None. Construct hierarchical index using the passed keys as the outermost level. If multiple levels passed, should contain tuples.
- `levels`: list of sequences, default None. Specific levels (unique values) to use for constructing a MultiIndex. Otherwise they will be inferred from the keys.
- `names`: list, default None. Names for the levels in the resulting hierarchical index.
- `verify_integrity`: boolean, default False. Check whether the new concatenated axis contains duplicates. This can be very expensive relative to the actual data concatenation.
- `copy`: boolean, default True. If False, do not copy data unnecessarily.

Without a little bit of context many of these arguments don't make much sense. Let's revisit the above example. Suppose we wanted to associate specific keys with each of the pieces of the chopped up DataFrame. We can do this using the `keys` argument:

```
In [6]: result = pd.concat(frames, keys=['x', 'y', 'z'])
```

df1				Result					
	A	B	C	D	A	B	C	D	
0	A0	B0	C0	D0	x 0	A0	B0	C0	D0
1	A1	B1	C1	D1	x 1	A1	B1	C1	D1
2	A2	B2	C2	D2	x 2	A2	B2	C2	D2
3	A3	B3	C3	D3	x 3	A3	B3	C3	D3
df2				Result					
	A	B	C	D	A	B	C	D	
4	A4	B4	C4	D4	y 4	A4	B4	C4	D4
5	A5	B5	C5	D5	y 5	A5	B5	C5	D5
6	A6	B6	C6	D6	y 6	A6	B6	C6	D6
7	A7	B7	C7	D7	y 7	A7	B7	C7	D7
df3				Result					
	A	B	C	D	A	B	C	D	
8	A8	B8	C8	D8	z 8	A8	B8	C8	D8
9	A9	B9	C9	D9	z 9	A9	B9	C9	D9
10	A10	B10	C10	D10	z 10	A10	B10	C10	D10
11	A11	B11	C11	D11	z 11	A11	B11	C11	D11

As you can see (if you've read the rest of the documentation), the resulting object's index has a *hierarchical index*. This means that we can now select out each chunk by key:

```
In [7]: result.loc['y']
```

Out[7]:

	A	B	C	D
4	A4	B4	C4	D4
5	A5	B5	C5	D5
6	A6	B6	C6	D6
7	A7	B7	C7	D7

It's not a stretch to see how this can be very useful. More detail on this functionality below.

Note: It is worth noting that `concat()` (and therefore `append()`) makes a full copy of the data, and that constantly reusing this function can create a significant performance hit. If you need to use the operation over several datasets, use a list comprehension.

```
frames = [ process_your_file(f) for f in files ]
result = pd.concat(frames)
```

Set logic on the other axes

When gluing together multiple DataFrames, you have a choice of how to handle the other axes (other than the one being concatenated). This can be done in the following two ways:

- Take the union of them all, `join='outer'`. This is the default option as it results in zero information loss.
- Take the intersection, `join='inner'`.

Here is an example of each of these methods. First, the default `join='outer'` behavior:

```
In [8]: df4 = pd.DataFrame({'B': ['B2', 'B3', 'B6', 'B7'],
   ....:                 'D': ['D2', 'D3', 'D6', 'D7'],
   ....:                 'F': ['F2', 'F3', 'F6', 'F7']},
   ....:                index=[2, 3, 6, 7])
....:
```

```
In [9]: result = pd.concat([df1, df4], axis=1, sort=False)
```

df1				df4			Result									
	A	B	C	D	B	D	F	A	B	C	D	B	D	F		
0	A0	B0	C0	D0	2	B2	D2	F2	0	A0	B0	C0	D0	NaN	NaN	NaN
1	A1	B1	C1	D1	3	B3	D3	F3	1	A1	B1	C1	D1	NaN	NaN	NaN
2	A2	B2	C2	D2	6	B6	D6	F6	2	A2	B2	C2	D2	B2	D2	F2
3	A3	B3	C3	D3	7	B7	D7	F7	3	A3	B3	C3	D3	B3	D3	F3
								6	NaN	NaN	NaN	NaN	B6	D6	F6	
								7	NaN	NaN	NaN	NaN	B7	D7	F7	

Warning: Changed in version 0.23.0.

The default behavior with `join='outer'` is to sort the other axis (columns in this case). In a future version of pandas, the default will be to not sort. We specified `sort=False` to opt in to the new behavior now.

Here is the same thing with `join='inner'`:

```
In [10]: result = pd.concat([df1, df4], axis=1, join='inner')
```

df1				df4			Result									
	A	B	C	D	B	D	F	A	B	C	D	B	D	F		
0	A0	B0	C0	D0	2	B2	D2	F2	2	A2	B2	C2	D2	B2	D2	F2
1	A1	B1	C1	D1	3	B3	D3	F3	3	A3	B3	C3	D3	B3	D3	F3
2	A2	B2	C2	D2	6	B6	D6	F6								
3	A3	B3	C3	D3	7	B7	D7	F7								

Lastly, suppose we just wanted to reuse the *exact index* from the original DataFrame:

```
In [11]: result = pd.concat([df1, df4], axis=1).reindex(df1.index)
```

Similarly, we could index before the concatenation:

```
In [12]: pd.concat([df1, df4.reindex(df1.index)], axis=1)
```

```
Out[12]:
```

	A	B	C	D	B	D	F
0	A0	B0	C0	D0	NaN	NaN	NaN
1	A1	B1	C1	D1	NaN	NaN	NaN
2	A2	B2	C2	D2	B2	D2	F2
3	A3	B3	C3	D3	B3	D3	F3

Concatenating using append

A useful shortcut to `concat()` are the `append()` instance methods on Series and DataFrame. These methods actually predated concat. They concatenate along `axis=0`, namely the index:

```
In [13]: result = df1.append(df2)
```

In the case of DataFrame, the indexes must be disjoint but the columns do not need to be:

```
In [14]: result = df1.append(df4, sort=False)
```

df1					Result					
	A	B	C	D		A	B	C	D	F
0	A0	B0	C0	D0		A0	B0	C0	D0	NaN
1	A1	B1	C1	D1		A1	B1	C1	D1	NaN
2	A2	B2	C2	D2		A2	B2	C2	D2	NaN
3	A3	B3	C3	D3		A3	B3	C3	D3	NaN

df4					Result					F
	B	D	F			A	B	C	D	F
2	B2	D2	F2			NaN	B2	NaN	D2	F2
3	B3	D3	F3			NaN	B3	NaN	D3	F3
6	B6	D6	F6			NaN	B6	NaN	D6	F6
7	B7	D7	F7			NaN	B7	NaN	D7	F7

append may take multiple objects to concatenate:

```
In [15]: result = df1.append([df2, df3])
```

df1					Result					
	A	B	C	D		A	B	C	D	
0	A0	B0	C0	D0		A0	B0	C0	D0	
1	A1	B1	C1	D1		A1	B1	C1	D1	
2	A2	B2	C2	D2		A2	B2	C2	D2	
3	A3	B3	C3	D3		A3	B3	C3	D3	

df2					Result					
	A	B	C	D		A	B	C	D	
4	A4	B4	C4	D4		A4	B4	C4	D4	
5	A5	B5	C5	D5		A5	B5	C5	D5	
6	A6	B6	C6	D6		A6	B6	C6	D6	
7	A7	B7	C7	D7		A7	B7	C7	D7	

df3					Result					
	A	B	C	D		A	B	C	D	
8	A8	B8	C8	D8		A8	B8	C8	D8	
9	A9	B9	C9	D9		A9	B9	C9	D9	
10	A10	B10	C10	D10		A10	B10	C10	D10	
11	A11	B11	C11	D11		A11	B11	C11	D11	

Note: Unlike the `append()` method, which appends to the original list and returns `None`, `append()` here **does not** modify `df1` and returns its copy with `df2` appended.

Ignoring indexes on the concatenation axis

For DataFrame objects which don't have a meaningful index, you may wish to append them and ignore the fact that they may have overlapping indexes. To do this, use the `ignore_index=True` argument:

```
In [16]: result = pd.concat([df1, df4], ignore_index=True, sort=False)
```

df1					Result				
	A	B	C	D	A	B	C	D	F
0	A0	B0	C0	D0	0	A0	B0	C0	D0
1	A1	B1	C1	D1	1	A1	B1	C1	D1
2	A2	B2	C2	D2	2	A2	B2	C2	D2
3	A3	B3	C3	D3	3	A3	B3	C3	D3

df4					Result				
	B	D	F		A	B	C	D	F
2	B2	D2	F2		4	NaN	B2	NaN	D2
3	B3	D3	F3		5	NaN	B3	NaN	D3
6	B6	D6	F6		6	NaN	B6	NaN	D6
7	B7	D7	F7		7	NaN	B7	NaN	D7

This is also a valid argument to `DataFrame.append()`:

```
In [17]: result = df1.append(df4, ignore_index=True, sort=False)
```

df1					Result				
	A	B	C	D	A	B	C	D	F
0	A0	B0	C0	D0	0	A0	B0	C0	D0
1	A1	B1	C1	D1	1	A1	B1	C1	D1
2	A2	B2	C2	D2	2	A2	B2	C2	D2
3	A3	B3	C3	D3	3	A3	B3	C3	D3

df4					Result				
	B	D	F		A	B	C	D	F
2	B2	D2	F2		4	NaN	B2	NaN	D2
3	B3	D3	F3		5	NaN	B3	NaN	D3
6	B6	D6	F6		6	NaN	B6	NaN	D6
7	B7	D7	F7		7	NaN	B7	NaN	D7

Concatenating with mixed ndims

You can concatenate a mix of Series and DataFrame objects. The Series will be transformed to DataFrame with the column name as the name of the Series.

```
In [18]: s1 = pd.Series(['X0', 'X1', 'X2', 'X3'], name='X')
```

```
In [19]: result = pd.concat([df1, s1], axis=1)
```

df1				s1	Result					
	A	B	C	D	X	A	B	C	D	X
0	A0	B0	C0	D0	X0	A0	B0	C0	D0	X0
1	A1	B1	C1	D1	X1	A1	B1	C1	D1	X1
2	A2	B2	C2	D2	X2	A2	B2	C2	D2	X2
3	A3	B3	C3	D3	X3	A3	B3	C3	D3	X3

Note: Since we're concatenating a Series to a DataFrame, we could have achieved the same result with DataFrame.assign(). To concatenate an arbitrary number of pandas objects (DataFrame or Series), use concat.

If unnamed Series are passed they will be numbered consecutively.

```
In [20]: s2 = pd.Series(['_0', '_1', '_2', '_3'])
```

```
In [21]: result = pd.concat([df1, s2, s2, s2], axis=1)
```

df1				s2	Result								
	A	B	C	D	_0	0	A	B	C	D	0	1	2
0	A0	B0	C0	D0	_0	0	A0	B0	C0	D0	_0	_0	_0
1	A1	B1	C1	D1	_1	1	A1	B1	C1	D1	_1	_1	_1
2	A2	B2	C2	D2	_2	2	A2	B2	C2	D2	_2	_2	_2
3	A3	B3	C3	D3	_3	3	A3	B3	C3	D3	_3	_3	_3

Passing ignore_index=True will drop all name references.

```
In [22]: result = pd.concat([df1, s1], axis=1, ignore_index=True)
```

df1				s1	Result					
	A	B	C	D	X	0	1	2	3	4
0	A0	B0	C0	D0	X0	0	A0	B0	C0	D0
1	A1	B1	C1	D1	X1	1	A1	B1	C1	D1
2	A2	B2	C2	D2	X2	2	A2	B2	C2	D2
3	A3	B3	C3	D3	X3	3	A3	B3	C3	D3

More concatenating with group keys

A fairly common use of the `keys` argument is to override the column names when creating a new DataFrame based on existing Series. Notice how the default behaviour consists on letting the resulting DataFrame inherit the parent Series' name, when these existed.

```
In [23]: s3 = pd.Series([0, 1, 2, 3], name='foo')

In [24]: s4 = pd.Series([0, 1, 2, 3])

In [25]: s5 = pd.Series([0, 1, 4, 5])

In [26]: pd.concat([s3, s4, s5], axis=1)
Out[26]:
   foo    0    1
0      0    0
1      1    1
2      2    2
3      3    3
```

Through the `keys` argument we can override the existing column names.

```
In [27]: pd.concat([s3, s4, s5], axis=1, keys=['red', 'blue', 'yellow'])
Out[27]:
     red   blue   yellow
0      0       0        0
1      1       1        1
2      2       2        4
3      3       3        5
```

Let's consider a variation of the very first example presented:

```
In [28]: result = pd.concat(frames, keys=['x', 'y', 'z'])
```

df1				Result						
	A	B	C	D		A	B	C	D	
0	A0	B0	C0	D0	x	0	AD	BD	CD	DD
1	A1	B1	C1	D1	x	1	A1	B1	C1	D1
2	A2	B2	C2	D2	x	2	A2	B2	C2	D2
3	A3	B3	C3	D3	x	3	A3	B3	C3	D3
df2										
	A	B	C	D	y	4	A4	B4	C4	D4
4	A4	B4	C4	D4	y	5	A5	B5	C5	D5
5	A5	B5	C5	D5	y	6	A6	B6	C6	D6
6	A6	B6	C6	D6	y	7	A7	B7	C7	D7
7	A7	B7	C7	D7	z	8	AB	BB	CB	DB
df3										
	A	B	C	D	z	9	AB	BB	C9	D9
8	A8	B8	C8	D8	z	10	A10	B10	C10	D10
9	A9	B9	C9	D9	z	11	A11	B11	C11	D11
10	A10	B10	C10	D10						
11	A11	B11	C11	D11						

You can also pass a dict to `concat` in which case the dict keys will be used for the `keys` argument (unless other keys are specified):

```
In [29]: pieces = {'x': df1, 'y': df2, 'z': df3}
```

```
In [30]: result = pd.concat(pieces)
```

df1					Result					
	A	B	C	D		A	B	C	D	
0	A0	B0	C0	D0	x	0	AD	BD	CD	DD
1	A1	B1	C1	D1	x	1	A1	B1	C1	D1
2	A2	B2	C2	D2	x	2	A2	B2	C2	D2
3	A3	B3	C3	D3	x	3	A3	B3	C3	D3
df2					y	4	A4	B4	C4	D4
df3					y	5	A5	B5	C5	D5
df4					y	6	A6	B6	C6	D6
df5					y	7	A7	B7	C7	D7
df6					z	8	AB	BB	CB	DB
df7					z	9	AB	BB	CB	DB
df8					z	10	A10	B10	C10	D10
df9					z	11	A11	B11	C11	D11

```
In [31]: result = pd.concat(pieces, keys=['z', 'y'])
```

df1					Result					
	A	B	C	D		A	B	C	D	
0	A0	B0	C0	D0	z	8	AB	BB	CB	DB
1	A1	B1	C1	D1	z	9	AB	BB	CB	DB
2	A2	B2	C2	D2	z	10	A10	B10	C10	D10
3	A3	B3	C3	D3	z	11	A11	B11	C11	D11
df2					y	4	A4	B4	C4	D4
df3					y	5	A5	B5	C5	D5
df4					y	6	A6	B6	C6	D6
df5					y	7	A7	B7	C7	D7
df6										
df7										
df8										
df9										

The MultiIndex created has levels that are constructed from the passed keys and the index of the DataFrame pieces:

```
In [32]: result.index.levels
Out[32]: FrozenList([['z', 'y'], [4, 5, 6, 7, 8, 9, 10, 11]])
```

If you wish to specify other levels (as will occasionally be the case), you can do so using the `levels` argument:

```
In [33]: result = pd.concat(pieces, keys=['x', 'y', 'z'],
.....:                         levels=[[ 'z', 'y', 'x', 'w']],
.....:                         names=['group_key'])
.....:
```

	A	B	C	D
0	A0	B0	C0	D0
1	A1	B1	C1	D1
2	A2	B2	C2	D2
3	A3	B3	C3	D3

	A	B	C	D
4	A4	B4	C4	D4
5	A5	B5	C5	D5
6	A6	B6	C6	D6
7	A7	B7	C7	D7

	A	B	C	D
8	A8	B8	C8	D8
9	A9	B9	C9	D9
10	A10	B10	C10	D10
11	A11	B11	C11	D11

	A	B	C	D
x 0	AD	BD	CD	DD
x 1	A1	B1	C1	D1
x 2	A2	B2	C2	D2
x 3	A3	B3	C3	D3
y 4	A4	B4	C4	D4
y 5	A5	B5	C5	D5
y 6	A6	B6	C6	D6
y 7	A7	B7	C7	D7
z 8	AB	BB	CB	DB
z 9	A9	B9	C9	D9
z 10	A10	B10	C10	D10
z 11	A11	B11	C11	D11

```
In [34]: result.index.levels
Out[34]: FrozenList([['z', 'y', 'x', 'w'], [0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11]])
```

This is fairly esoteric, but it is actually necessary for implementing things like GroupBy where the order of a categorical variable is meaningful.

Appending rows to a DataFrame

While not especially efficient (since a new object must be created), you can append a single row to a DataFrame by passing a Series or dict to `append`, which returns a new DataFrame as above.

```
In [35]: s2 = pd.Series(['X0', 'X1', 'X2', 'X3'], index=['A', 'B', 'C', 'D'])
In [36]: result = df1.append(s2, ignore_index=True)
```

df1					Result				
	A	B	C	D		A	B	C	D
0	A0	B0	C0	D0					
1	A1	B1	C1	D1					
2	A2	B2	C2	D2					
3	A3	B3	C3	D3					

s2					Result				
	A	B	C	D		A	B	C	D
		X0							
	A		X1						
	B			X2					
	C				X3				
	D								

You should use `ignore_index` with this method to instruct DataFrame to discard its index. If you wish to preserve the index, you should construct an appropriately-indexed DataFrame and append or concatenate those objects.

You can also pass a list of dicts or Series:

```
In [37]: dicts = [{‘A’: 1, ‘B’: 2, ‘C’: 3, ‘X’: 4},  
.....: {‘A’: 5, ‘B’: 6, ‘C’: 7, ‘Y’: 8}]  
.....:  
  
In [38]: result = df1.append(dicts, ignore_index=True, sort=False)
```

df1					Result				
	A	B	C	D		A	B	C	D
0	A0	B0	C0	D0					
1	A1	B1	C1	D1					
2	A2	B2	C2	D2					
3	A3	B3	C3	D3					

dicts					Result				
	A	B	C	X		D	X	Y	
0	1	2	3	4.0		D0	NaN	NaN	
1	5	6	7	NaN		D1	NaN	NaN	

3.4.2 Database-style DataFrame or named Series joining/merging

pandas has full-featured, **high performance** in-memory join operations idiomatically very similar to relational databases like SQL. These methods perform significantly better (in some cases well over an order of magnitude better) than other open source implementations (like `base::merge.data.frame` in R). The reason for this is careful algorithmic design and the internal layout of the data in DataFrame.

See the [cookbook](#) for some advanced strategies.

Users who are familiar with SQL but new to pandas might be interested in a [comparison with SQL](#).

pandas provides a single function, `merge()`, as the entry point for all standard database join operations between DataFrame or named Series objects:

```
pd.merge(left, right, how='inner', on=None, left_on=None, right_on=None,
        left_index=False, right_index=False, sort=True,
        suffixes=('_x', '_y'), copy=True, indicator=False,
        validate=None)
```

- `left`: A DataFrame or named Series object.
- `right`: Another DataFrame or named Series object.
- `on`: Column or index level names to join on. Must be found in both the left and right DataFrame and/or Series objects. If not passed and `left_index` and `right_index` are `False`, the intersection of the columns in the DataFrames and/or Series will be inferred to be the join keys.
- `left_on`: Columns or index levels from the left DataFrame or Series to use as keys. Can either be column names, index level names, or arrays with length equal to the length of the DataFrame or Series.
- `right_on`: Columns or index levels from the right DataFrame or Series to use as keys. Can either be column names, index level names, or arrays with length equal to the length of the DataFrame or Series.
- `left_index`: If `True`, use the index (row labels) from the left DataFrame or Series as its join key(s). In the case of a DataFrame or Series with a MultiIndex (hierarchical), the number of levels must match the number of join keys from the right DataFrame or Series.
- `right_index`: Same usage as `left_index` for the right DataFrame or Series.
- `how`: One of '`left`', '`right`', '`outer`', '`inner`'. Defaults to `inner`. See below for more detailed description of each method.
- `sort`: Sort the result DataFrame by the join keys in lexicographical order. Defaults to `True`, setting to `False` will improve performance substantially in many cases.
- `suffixes`: A tuple of string suffixes to apply to overlapping columns. Defaults to `(''_x'', ''_y'')`.
- `copy`: Always copy data (default `True`) from the passed DataFrame or named Series objects, even when reindexing is not necessary. Cannot be avoided in many cases but may improve performance / memory usage. The cases where copying can be avoided are somewhat pathological but this option is provided nonetheless.
- `indicator`: Add a column to the output DataFrame called `_merge` with information on the source of each row. `_merge` is Categorical-type and takes on a value of `left_only` for observations whose merge key only appears in '`left`' DataFrame or Series, `right_only` for observations whose merge key only appears in '`right`' DataFrame or Series, and `both` if the observation's merge key is found in both.
- `validate`: string, default `None`. If specified, checks if merge is of specified type.
 - “`one_to_one`” or “`1:1`”: checks if merge keys are unique in both left and right datasets.
 - “`one_to_many`” or “`1:m`”: checks if merge keys are unique in left dataset.
 - “`many_to_one`” or “`m:1`”: checks if merge keys are unique in right dataset.
 - “`many_to_many`” or “`m:m`”: allowed, but does not result in checks.

New in version 0.21.0.

Note: Support for specifying index levels as the `on`, `left_on`, and `right_on` parameters was added in version 0.23.0. Support for merging named Series objects was added in version 0.24.0.

The return type will be the same as `left`. If `left` is a DataFrame or named Series and `right` is a subclass of DataFrame, the return type will still be DataFrame.

`merge` is a function in the pandas namespace, and it is also available as a DataFrame instance method `merge()`, with the calling DataFrame being implicitly considered the left object in the join.

The related `join()` method, uses `merge` internally for the index-on-index (by default) and column(s)-on-index join. If you are joining on index only, you may wish to use `DataFrame.join` to save yourself some typing.

Brief primer on merge methods (relational algebra)

Experienced users of relational databases like SQL will be familiar with the terminology used to describe join operations between two SQL-table like structures (`DataFrame` objects). There are several cases to consider which are very important to understand:

- **one-to-one** joins: for example when joining two `DataFrame` objects on their indexes (which must contain unique values).
- **many-to-one** joins: for example when joining an index (unique) to one or more columns in a different `DataFrame`.
- **many-to-many** joins: joining columns on columns.

Note: When joining columns on columns (potentially a many-to-many join), any indexes on the passed `DataFrame` objects **will be discarded**.

It is worth spending some time understanding the result of the **many-to-many** join case. In SQL / standard relational algebra, if a key combination appears more than once in both tables, the resulting table will have the **Cartesian product** of the associated data. Here is a very basic example with one unique key combination:

```
In [39]: left = pd.DataFrame({'key': ['K0', 'K1', 'K2', 'K3'],
....:                   'A': ['A0', 'A1', 'A2', 'A3'],
....:                   'B': ['B0', 'B1', 'B2', 'B3']})

In [40]: right = pd.DataFrame({'key': ['K0', 'K1', 'K2', 'K3'],
....:                   'C': ['C0', 'C1', 'C2', 'C3'],
....:                   'D': ['D0', 'D1', 'D2', 'D3']})

In [41]: result = pd.merge(left, right, on='key')
```

left			right			Result							
	key	A		key	C	D		key	A	B	C	D	
0	K0	A0	B0	0	C0	D0		0	A0	B0	C0	D0	
1	K1	A1	B1	1	C1	D1		1	A1	B1	C1	D1	
2	K2	A2	B2	2	C2	D2		2	A2	B2	C2	D2	
3	K3	A3	B3	3	C3	D3		3	A3	B3	C3	D3	

Here is a more complicated example with multiple join keys. Only the keys appearing in `left` and `right` are present (the intersection), since `how='inner'` by default.

```
In [42]: left = pd.DataFrame({'key1': ['K0', 'K0', 'K1', 'K2'],
....:                   'key2': ['K0', 'K1', 'K0', 'K1'],
....:                   'A': ['A0', 'A1', 'A2', 'A3'],
....:                   'B': ['B0', 'B1', 'B2', 'B3']})
```

(continues on next page)

(continued from previous page)

```
In [43]: right = pd.DataFrame({'key1': ['K0', 'K1', 'K1', 'K2'],
....:                   'key2': ['K0', 'K0', 'K0', 'K0'],
....:                   'C': ['C0', 'C1', 'C2', 'C3'],
....:                   'D': ['D0', 'D1', 'D2', 'D3']})
```

```
In [44]: result = pd.merge(left, right, on=['key1', 'key2'])
```

left				right				Result							
	key1	key2	A		key1	key2	C	D		key1	key2	A	B	C	D
0	K0	K0	A0	B0	0	K0	C0	D0	0	K0	K0	A0	B0	C0	D0
1	K0	K1	A1	B1	1	K1	C1	D1	1	K1	K0	A2	B2	C1	D1
2	K1	K0	A2	B2	2	K1	C2	D2	2	K1	K0	A2	B2	C2	D2
3	K2	K1	A3	B3	3	K2	C3	D3							

The `how` argument to `merge` specifies how to determine which keys are to be included in the resulting table. If a key combination **does not appear** in either the left or right tables, the values in the joined table will be NA. Here is a summary of the `how` options and their SQL equivalent names:

Merge method	SQL Join Name	Description
left	LEFT OUTER JOIN	Use keys from left frame only
right	RIGHT OUTER JOIN	Use keys from right frame only
outer	FULL OUTER JOIN	Use union of keys from both frames
inner	INNER JOIN	Use intersection of keys from both frames

```
In [45]: result = pd.merge(left, right, how='left', on=['key1', 'key2'])
```

left				right				Result							
	key1	key2	A		key1	key2	C	D		key1	key2	A	B	C	D
0	K0	K0	A0	B0	0	K0	C0	D0	0	K0	K0	A0	B0	C0	D0
1	K0	K1	A1	B1	1	K1	C1	D1	1	K0	K1	A1	B1	NaN	NaN
2	K1	K0	A2	B2	2	K1	C2	D2	2	K1	K0	A2	B2	C1	D1
3	K2	K1	A3	B3	3	K2	C3	D3	3	K1	K0	A2	B2	C2	D2
									4	K2	K1	A3	B3	NaN	NaN

```
In [46]: result = pd.merge(left, right, how='right', on=['key1', 'key2'])
```

left				right				Result								
	key1	key2	A		key1	key2	C		key1	key2	A	B	C	D		
0	K0	K0	A0	B0	0	K0	K0	C0	D0	0	K0	K0	A0	B0	C0	D0
1	K0	K1	A1	B1	1	K1	K0	C1	D1	1	K1	K0	A2	B2	C1	D1
2	K1	K0	A2	B2	2	K1	K0	C2	D2	2	K1	K0	A2	B2	C2	D2
3	K2	K1	A3	B3	3	K2	K0	C3	D3	3	K2	K0	NaN	NaN	C3	D3

```
In [47]: result = pd.merge(left, right, how='outer', on=['key1', 'key2'])
```

left				right				Result								
	key1	key2	A		key1	key2	C		key1	key2	A	B	C	D		
0	K0	K0	A0	B0	0	K0	K0	C0	D0	0	K0	K0	A0	B0	C0	D0
1	K0	K1	A1	B1	1	K1	K0	C1	D1	1	K0	K1	A1	B1	NaN	NaN
2	K1	K0	A2	B2	2	K1	K0	C2	D2	2	K1	K0	A2	B2	C1	D1
3	K2	K1	A3	B3	3	K2	K0	C3	D3	3	K1	K0	A2	B2	C2	D2
										4	K2	K1	A3	B3	NaN	NaN
										5	K2	K0	NaN	NaN	C3	D3

```
In [48]: result = pd.merge(left, right, how='inner', on=['key1', 'key2'])
```

left				right				Result								
	key1	key2	A		key1	key2	C		key1	key2	A	B	C	D		
0	K0	K0	A0	B0	0	K0	K0	C0	D0	0	K0	K0	A0	B0	C0	D0
1	K0	K1	A1	B1	1	K1	K0	C1	D1	1	K1	K0	A2	B2	C1	D1
2	K1	K0	A2	B2	2	K1	K0	C2	D2	2	K1	K0	A2	B2	C2	D2
3	K2	K1	A3	B3	3	K2	K0	C3	D3							

Here is another example with duplicate join keys in DataFrames:

```
In [49]: left = pd.DataFrame({'A': [1, 2], 'B': [2, 2]})
```

```
In [50]: right = pd.DataFrame({'A': [4, 5, 6], 'B': [2, 2, 2]})
```

```
In [51]: result = pd.merge(left, right, on='B', how='outer')
```

left	right	Result		
		A_x	B	A_y
		0	1	4
		1	1	5
		2	1	6
		3	2	4
		4	2	5
		5	2	6

Warning: Joining / merging on duplicate keys can cause a returned frame that is the multiplication of the row dimensions, which may result in memory overflow. It is the user's responsibility to manage duplicate values in keys before joining large DataFrames.

Checking for duplicate keys

New in version 0.21.0.

Users can use the `validate` argument to automatically check whether there are unexpected duplicates in their merge keys. Key uniqueness is checked before merge operations and so should protect against memory overflows. Checking key uniqueness is also a good way to ensure user data structures are as expected.

In the following example, there are duplicate values of B in the right DataFrame. As this is not a one-to-one merge – as specified in the `validate` argument – an exception will be raised.

```
In [52]: left = pd.DataFrame({'A' : [1,2], 'B' : [1, 2]})

In [53]: right = pd.DataFrame({'A' : [4,5,6], 'B': [2, 2, 2]})
```

```
In [53]: result = pd.merge(left, right, on='B', how='outer', validate="one_to_one")
...
MergeError: Merge keys are not unique in right dataset; not a one-to-one merge
```

If the user is aware of the duplicates in the right DataFrame but wants to ensure there are no duplicates in the left DataFrame, one can use the `validate='one_to_many'` argument instead, which will not raise an exception.

```
In [54]: pd.merge(left, right, on='B', how='outer', validate="one_to_many")
Out[54]:
   A_x  B  A_y
0    1  1  NaN
1    2  2  4.0
2    2  2  5.0
3    2  2  6.0
```

The merge indicator

`merge()` accepts the argument `indicator`. If `True`, a Categorical-type column called `_merge` will be added to the output object that takes on values:

Observation Origin	_merge value
Merge key only in 'left' frame	<code>left_only</code>
Merge key only in 'right' frame	<code>right_only</code>
Merge key in both frames	<code>both</code>

```
In [55]: df1 = pd.DataFrame({'col1': [0, 1], 'col_left': ['a', 'b']})  
  
In [56]: df2 = pd.DataFrame({'col1': [1, 2, 2], 'col_right': [2, 2, 2]})  
  
In [57]: pd.merge(df1, df2, on='col1', how='outer', indicator=True)  
Out[57]:  
      col1  col_left  col_right      _merge  
0        0         a        NaN  left_only  
1        1         b        2.0      both  
2        2        NaN        2.0  right_only  
3        2        NaN        2.0  right_only
```

The `indicator` argument will also accept string arguments, in which case the indicator function will use the value of the passed string as the name for the indicator column.

```
In [58]: pd.merge(df1, df2, on='col1', how='outer', indicator='indicator_column')  
Out[58]:  
      col1  col_left  col_right  indicator_column  
0        0         a        NaN  left_only  
1        1         b        2.0      both  
2        2        NaN        2.0  right_only  
3        2        NaN        2.0  right_only
```

Merge dtypes

Merging will preserve the dtype of the join keys.

```
In [59]: left = pd.DataFrame({'key': [1], 'v1': [10]})  
  
In [60]: left  
Out[60]:  
      key  v1  
0     1   10  
  
In [61]: right = pd.DataFrame({'key': [1, 2], 'v1': [20, 30]})  
  
In [62]: right  
Out[62]:  
      key  v1  
0     1   20  
1     2   30
```

We are able to preserve the join keys:

```
In [63]: pd.merge(left, right, how='outer')
Out[63]:
   key    v1
0     1   10
1     1   20
2     2   30

In [64]: pd.merge(left, right, how='outer').dtypes
Out[64]:
key      int64
v1      int64
dtype: object
```

Of course if you have missing values that are introduced, then the resulting dtype will be upcast.

```
In [65]: pd.merge(left, right, how='outer', on='key')
Out[65]:
   key    v1_x    v1_y
0     1   10.0     20
1     2     NaN     30

In [66]: pd.merge(left, right, how='outer', on='key').dtypes
Out[66]:
key      int64
v1_x    float64
v1_y      int64
dtype: object
```

Merging will preserve category dtypes of the mergands. See also the section on [categoricals](#).

The left frame.

```
In [67]: from pandas.api.types import CategoricalDtype

In [68]: X = pd.Series(np.random.choice(['foo', 'bar'], size=(10,)))

In [69]: X = X.astype(CategoricalDtype(categories=['foo', 'bar']))

In [70]: left = pd.DataFrame({'X': X,
....:                     'Y': np.random.choice(['one', 'two', 'three'],
....:                               size=(10,))})

In [71]: left
Out[71]:
   X      Y
0  foo    one
1  bar   three
2  foo    one
3  bar    one
4  bar   three
5  foo    one
6  bar    two
7  bar    two
8  bar    one
9  foo   three

In [72]: left.dtypes
```

(continues on next page)

(continued from previous page)

```
Out[72]:  
X    category  
Y    object  
dtype: object
```

The right frame.

```
In [73]: right = pd.DataFrame({'X': pd.Series(['foo', 'bar'],  
.....:                               dtype=CategoricalDtype(['foo', 'bar'])),  
.....:  
.....:  
.....:  
  
In [74]: right  
Out[74]:  
   X    Z  
0  foo  1  
1  bar  2  
  
In [75]: right.dtypes  
Out[75]:  
X    category  
Z    int64  
dtype: object
```

The merged result:

```
In [76]: result = pd.merge(left, right, how='outer')  
  
In [77]: result  
Out[77]:  
       X      Y    Z  
0    foo    one  1  
1    foo    one  1  
2    foo    one  1  
3    foo  three  1  
4    bar  three  2  
5    bar    one  2  
6    bar  three  2  
7    bar    two  2  
8    bar    two  2  
9    bar    one  2  
  
In [78]: result.dtypes  
Out[78]:  
X    category  
Y    object  
Z    int64  
dtype: object
```

Note: The category dtypes must be *exactly* the same, meaning the same categories and the ordered attribute. Otherwise the result will coerce to the categories' dtype.

Note: Merging on category dtypes that are the same can be quite performant compared to object dtype merging.

Joining on index

`DataFrame.join()` is a convenient method for combining the columns of two potentially differently-indexed `DataFrames` into a single result `DataFrame`. Here is a very basic example:

```
In [79]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2'],
....:                           'B': ['B0', 'B1', 'B2']},
....:                           index=['K0', 'K1', 'K2'])

In [80]: right = pd.DataFrame({'C': ['C0', 'C2', 'C3'],
....:                           'D': ['D0', 'D2', 'D3']},
....:                           index=['K0', 'K2', 'K3'])

In [81]: result = left.join(right)
```

left		right		Result						
		C	D	A	B	C	D			
K0	A0	B0	K0	C0	D0	K0	A0	B0	C0	D0
K1	A1	B1	K2	C2	D2	K1	A1	B1	NaN	NaN
K2	A2	B2	K3	C3	D3	K2	A2	B2	C2	D2

```
In [82]: result = left.join(right, how='outer')
```

left		right		Result						
		C	D	A	B	C	D			
K0	A0	B0	K0	C0	D0	K0	A0	B0	C0	D0
K1	A1	B1	K2	C2	D2	K1	A1	B1	NaN	NaN
K2	A2	B2	K3	C3	D3	K2	A2	B2	C2	D2
				K3	NaN	NaN	C3	D3		

The same as above, but with `how='inner'`.

```
In [83]: result = left.join(right, how='inner')
```

left		right		Result						
		C	D	A	B	C	D			
K0	A0	B0	K0	C0	D0	K0	A0	B0	C0	D0
K1	A1	B1	K2	C2	D2	K2	A2	B2	C2	D2
K2	A2	B2	K3	C3	D3	K2	A2	B2	C2	D2

The data alignment here is on the indexes (row labels). This same behavior can be achieved using `merge` plus additional arguments instructing it to use the indexes:

```
In [84]: result = pd.merge(left, right, left_index=True, right_index=True, how='outer'
                         ↪')
```

left		right		Result			
		C	D	A	B	C	D
K0	A0	B0	D0	K0	A0	B0	D0
K1	A1	B1	D2	K1	A1	B1	NaN
K2	A2	B2	D3	K2	A2	B2	C2
				K3	NaN	NaN	C3
							D3

```
In [85]: result = pd.merge(left, right, left_index=True, right_index=True, how='inner'
                         ↪');
```

left		right		Result			
		C	D	A	B	C	D
K0	A0	B0	D0	K0	A0	B0	D0
K1	A1	B1	D2	K2	A2	B2	C2
K2	A2	B2	D3				D2

Joining key columns on an index

`join()` takes an optional `on` argument which may be a column or multiple column names, which specifies that the passed DataFrame is to be aligned on that column in the DataFrame. These two function calls are completely equivalent:

```
left.join(right, on=key_or_keys)
pd.merge(left, right, left_on=key_or_keys, right_index=True,
         how='left', sort=False)
```

Obviously you can choose whichever form you find more convenient. For many-to-one joins (where one of the DataFrame's is already indexed by the join key), using `join` may be more convenient. Here is a simple example:

```
In [86]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2', 'A3'],
                             ....:                 'B': ['B0', 'B1', 'B2', 'B3'],
                             ....:                 'key': ['K0', 'K1', 'K0', 'K1']})

In [87]: right = pd.DataFrame({'C': ['C0', 'C1'],
                             ....:                 'D': ['D0', 'D1']},
                             ....:                 index=['K0', 'K1'])

In [88]: result = left.join(right, on='key')
```

left			right		Result							
	A	B	key		C	D	A	B	key	C	D	
0	A0	B0	K0				0	A0	B0	K0	C0	D0
1	A1	B1	K1	K0	C0	D0	1	A1	B1	K1	C1	D1
2	A2	B2	K0	K1	C1	D1	2	A2	B2	K0	C0	D0
3	A3	B3	K1				3	A3	B3	K1	C1	D1

```
In [89]: result = pd.merge(left, right, left_on='key', right_index=True,
....:                      how='left', sort=False);
```

left			right		Result							
	A	B	key		C	D	A	B	key	C	D	
0	A0	B0	K0				0	A0	B0	K0	C0	D0
1	A1	B1	K1	K0	C0	D0	1	A1	B1	K1	C1	D1
2	A2	B2	K0	K1	C1	D1	2	A2	B2	K0	C0	D0
3	A3	B3	K1				3	A3	B3	K1	C1	D1

the passed DataFrame must have a MultiIndex:

```
In [90]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2', 'A3'],
....: 'B': ['B0', 'B1', 'B2', 'B3'],
....: 'key1': ['K0', 'K0', 'K1', 'K2'],
....: 'key2': ['K0', 'K1', 'K0', 'K1']})
```

```
In [91]: index = pd.MultiIndex.from_tuples([('K0', 'K0'), ('K1', 'K0'),
....: ('K2', 'K0'), ('K2', 'K1')])
```

```
In [92]: right = pd.DataFrame({'C': ['C0', 'C1', 'C2', 'C3'],
....: 'D': ['D0', 'D1', 'D2', 'D3']},
....: index=index)
```

To join on multiple keys,

Now this can be joined by passing the two key column names:

```
In [93]: result = left.join(right, on=['key1', 'key2'])
```

left				right		Result					
	A	B	key1	C	D	A	B	key1	C	D	
0	A0	B0	K0	C0	D0	0	A0	B0	K0	C0	D0
1	A1	B1	K0	C1	D1	1	A1	B1	K0	NaN	NaN
2	A2	B2	K1	C2	D2	2	A2	B2	K1	C1	D1
3	A3	B3	K2	C3	D3	3	A3	B3	K2	C3	D3

The

default for `DataFrame.join` is to perform a left join (essentially a “VLOOKUP” operation, for Excel users), which uses only the keys found in the calling DataFrame. Other join types, for example inner join, can be just as easily

performed:

```
In [94]: result = left.join(right, on=['key1', 'key2'], how='inner')
```

left				right		Result				
	A	B	key1	C	D	A	B	key1	C	D
0	A0	B0	K0	C0	D0	0	A0	K0	C0	D0
1	A1	B1	K0	C1	D1	2	A2	K1	C1	D1
2	A2	B2	K1	C2	D2	3	A3	K2	C2	D2
3	A3	B3	K2	C3	D3					

As you can see, this drops any rows where there was no match.

Joining a single Index to a MultiIndex

You can join a singly-indexed DataFrame with a level of a MultiIndexed DataFrame. The level will match on the name of the index of the singly-indexed frame against a level name of the MultiIndexed frame.

```
In [95]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2'],
.....:                  'B': ['B0', 'B1', 'B2']},
.....:                  index=pd.Index(['K0', 'K1', 'K2'], name='key'))
.....:

In [96]: index = pd.MultiIndex.from_tuples([('K0', 'Y0'), ('K1', 'Y1'),
.....:                                         ('K2', 'Y2'), ('K2', 'Y3')],
.....:                                         names=['key', 'Y'])
.....:

In [97]: right = pd.DataFrame({'C': ['C0', 'C1', 'C2', 'C3'],
.....:                  'D': ['D0', 'D1', 'D2', 'D3']},
.....:                  index=index)
.....:

In [98]: result = left.join(right, how='inner')
```

left			right		Result			
	A	B	C	D	A	B	C	D
K0	A0	B0	K0	C0	AD	B0	C0	D0
K1	A1	B1	K1	C1	A1	B1	C1	D1
K2	A2	B2	K2	C2	A2	B2	C2	D2
K2			K2	C3	A2	B2	C3	D3

This is equivalent but less verbose and more memory efficient / faster than this.

```
In [99]: result = pd.merge(left.reset_index(), right.reset_index(),
.....:                  on=['key'], how='inner').set_index(['key', 'Y'])
```

Joining with two MultiIndexes

This is supported in a limited way, provided that the index for the right argument is completely used in the join, and is a subset of the indices in the left argument, as in this example:

```
In [100]: leftindex = pd.MultiIndex.from_product([list('abc'), list('xy'), [1, 2]],
.....:                               names=['abc', 'xy', 'num'])
.....:

In [101]: left = pd.DataFrame({'v1': range(12)}, index=leftindex)

In [102]: left
Out[102]:
      v1
abc xy num
a   x  1    0
     2    1
     y  1    2
     2    3
b   x  1    4
     2    5
     y  1    6
     2    7
c   x  1    8
     2    9
     y  1   10
     2   11

In [103]: rightindex = pd.MultiIndex.from_product([list('abc'), list('xy')],
.....:                               names=['abc', 'xy'])
.....:

In [104]: right = pd.DataFrame({'v2': [100 * i for i in range(1, 7)]}, index=rightindex)

In [105]: right
Out[105]:
      v2
abc xy
a   x  100
     y  200
b   x  300
     y  400
c   x  500
     y  600
```

(continues on next page)

(continued from previous page)

```
In [106]: left.join(right, on=['abc', 'xy'], how='inner')
Out[106]:
      v1    v2
abc xy num
a   x  1   0  100
     2   1  100
     y  1   2  200
     2   3  200
b   x  1   4  300
     2   5  300
     y  1   6  400
     2   7  400
c   x  1   8  500
     2   9  500
     y  1  10  600
     2  11  600
```

If that condition is not satisfied, a join with two multi-indexes can be done using the following code.

```
In [107]: leftindex = pd.MultiIndex.from_tuples([('K0', 'X0'), ('K0', 'X1'),
.....:                               ('K1', 'X2')], names=['key', 'X'])
.....:
.....:
.....:

In [108]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2'],
.....:                           'B': ['B0', 'B1', 'B2']},
.....:                           index=leftindex)
.....:

In [109]: rightindex = pd.MultiIndex.from_tuples([('K0', 'Y0'), ('K1', 'Y1'),
.....:                               ('K2', 'Y2'), ('K2', 'Y3')], names=['key', 'Y'])
.....:
.....:
.....:

In [110]: right = pd.DataFrame({'C': ['C0', 'C1', 'C2', 'C3'],
.....:                           'D': ['D0', 'D1', 'D2', 'D3']},
.....:                           index=rightindex)
.....:

In [111]: result = pd.merge(left.reset_index(), right.reset_index(),
.....:                         on=['key'], how='inner').set_index(['key', 'X', 'Y'])
.....:
```

Merging on a combination of columns and index levels

New in version 0.23.

Strings passed as the `on`, `left_on`, and `right_on` parameters may refer to either column names or index level names. This enables merging `DataFrame` instances on a combination of index levels and columns without resetting indexes.

```
In [112]: left_index = pd.Index(['K0', 'K0', 'K1', 'K2'], name='key1')

In [113]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2', 'A3'],
.....:                 'B': ['B0', 'B1', 'B2', 'B3'],
.....:                 'key2': ['K0', 'K1', 'K0', 'K1']},
.....:                 index=left_index)
.....:

In [114]: right_index = pd.Index(['K0', 'K1', 'K2', 'K2'], name='key1')

In [115]: right = pd.DataFrame({'C': ['C0', 'C1', 'C2', 'C3'],
.....:                 'D': ['D0', 'D1', 'D2', 'D3'],
.....:                 'key2': ['K0', 'K0', 'K0', 'K1']},
.....:                 index=right_index)
.....:

In [116]: result = left.merge(right, on=['key1', 'key2'])
```

left			right			Result					
	A	B	C	D	key2		A	B	key2	C	D
K0	A0	B0	C0	D0	K0	K0	A0	B0	K0	C0	D0
K0	A1	B1	C1	D1	K0	K1	A2	B2	K0	C1	D1
K1	A2	B2	C2	D2	K0	K2	A3	B3	K1	C3	D3
K2	A3	B3	C3	D3	K1						

Note: When `DataFrames` are merged on a string that matches an index level in both frames, the index level is preserved as an index level in the resulting `DataFrame`.

Note: When `DataFrames` are merged using only some of the levels of a `MultiIndex`, the extra levels will be dropped from the resulting merge. In order to preserve those levels, use `reset_index` on those level names to move those levels to columns prior to doing the merge.

Note: If a string matches both a column name and an index level name, then a warning is issued and the column takes precedence. This will result in an ambiguity error in a future version.

Overlapping value columns

The merge suffixes argument takes a tuple of list of strings to append to overlapping column names in the input DataFrames to disambiguate the result columns:

```
In [117]: left = pd.DataFrame({'k': ['K0', 'K1', 'K2'], 'v': [1, 2, 3]})

In [118]: right = pd.DataFrame({'k': ['K0', 'K0', 'K3'], 'v': [4, 5, 6]})

In [119]: result = pd.merge(left, right, on='k')
```

left		right		Result		
	k	v		k	v	
0	K0	1	0	K0	4	0
1	K1	2	1	K0	5	1
2	K2	3	2	K3	6	

```
In [120]: result = pd.merge(left, right, on='k', suffixes=['_l', '_r'])
```

left		right		Result		
	k	v		k	v	
0	K0	1	0	K0	4	0
1	K1	2	1	K0	5	1
2	K2	3	2	K3	6	

DataFrame.join() has lsuffix and rsuffix arguments which behave similarly.

```
In [121]: left = left.set_index('k')

In [122]: right = right.set_index('k')

In [123]: result = left.join(right, lsuffix='_l', rsuffix='_r')
```

left		right		Result	
	v		v	v_l	v_r
K0	1	K0	4	K0	1 4.0
K1	2	K0	5	K0	1 5.0
K2	3	K3	6	K1	2 NaN
				K2	3 NaN

Joining multiple DataFrames

A list or tuple of DataFrames can also be passed to `join()` to join them together on their indexes.

```
In [124]: right2 = pd.DataFrame({'v': [7, 8, 9]}, index=['K1', 'K1', 'K2'])

In [125]: result = left.join([right, right2])
```

left	right	right2	Result
			v_x v_y v
K0 1	K0 4	K1 7	K0 1 4.0 NaN
K1 2	K0 5	K1 8	K0 1 5.0 NaN
K2 3	K3 6	K2 9	K1 2 NaN 7.0
			K1 2 NaN 8.0
			K2 3 NaN 9.0

Merging together values within Series or DataFrame columns

Another fairly common situation is to have two like-indexed (or similarly indexed) Series or DataFrame objects and wanting to “patch” values in one object from values for matching indices in the other. Here is an example:

```
In [126]: df1 = pd.DataFrame([[np.nan, 3., 5.], [-4.6, np.nan, np.nan],
.....:                   [np.nan, 7., np.nan]])
.....:

In [127]: df2 = pd.DataFrame([[-42.6, np.nan, -8.2], [-5., 1.6, 4.]],
.....:                   index=[1, 2])
.....:
```

For this, use the `combine_first()` method:

```
In [128]: result = df1.combine_first(df2)
```

df1	df2	Result
		0 1 2
0 NaN 3.0 5.0	1 -42.6 NaN -8.2	0 NaN 3.0 5.0
1 -4.6 NaN NaN	2 -5.0 1.6 4.0	1 -4.6 NaN -8.2
2 NaN 7.0 NaN		2 -5.0 7.0 4.0

Note that this method only takes values from the right DataFrame if they are missing in the left DataFrame. A related method, `update()`, alters non-NA values in place:

```
In [129]: df1.update(df2)
```

df1				df2			Result				
	0	1	2		0	1	2		0	1	2
0	NaN	3.0	5.0	1	-42.6	NaN	-8.2	2	NaN	3.0	5.0
1	-4.6	NaN	NaN	2	-5.0	1.6	4.0		-42.6	NaN	-8.2
2	NaN	7.0	NaN					2	-5.0	1.6	4.0

3.4.3 Timeseries friendly merging

Merging ordered data

A `merge_ordered()` function allows combining time series and other ordered data. In particular it has an optional `fill_method` keyword to fill/interpolate missing data:

```
In [130]: left = pd.DataFrame({'k': ['K0', 'K1', 'K1', 'K2'],
.....:                   'lv': [1, 2, 3, 4],
.....:                   's': ['a', 'b', 'c', 'd']}))
.....:

In [131]: right = pd.DataFrame({'k': ['K1', 'K2', 'K4'],
.....:                      'rv': [1, 2, 3]})

In [132]: pd.merge_ordered(left, right, fill_method='ffill', left_by='s')
Out[132]:
      k    lv  s    rv
0   K0  1.0  a  NaN
1   K1  1.0  a  1.0
2   K2  1.0  a  2.0

12  K4  4.0  d  3.0
```

Merging asof

A `merge_asof()` is similar to an ordered left-join except that we match on nearest key rather than equal keys. For each row in the `left` DataFrame, we select the last row in the `right` DataFrame whose `on` key is less than the left's key. Both DataFrames must be sorted by the key.

Optionally an asof merge can perform a group-wise merge. This matches the `by` key equally, in addition to the nearest match on the `on` key.

For example; we might have `trades` and `quotes` and we want to asof merge them.

```
In [133]: trades = pd.DataFrame({
.....:     'time': pd.to_datetime(['20160525 13:30:00.023',
.....:                           '20160525 13:30:00.038',
```

(continues on next page)

(continued from previous page)

```

.....
.....:                               '20160525 13:30:00.048',
.....:                               '20160525 13:30:00.048',
.....:                               '20160525 13:30:00.048']),
.....:     'ticker': ['MSFT', 'MSFT',

.....:             720.93, 98.01, 720.88, 52.03}],
.....:     columns=['time', 'ticker', 'bid', 'ask'])
.....:
.....

```

In [135]: trades

Out[135]:

	time	ticker	price	quantity
0	2016-05-25 13:30:00.023	MSFT	51.95	75
1	2016-05-25 13:30:00.038	MSFT	51.95	155
2	2016-05-25 13:30:00.048	GOOG	720.77	100
3	2016-05-25 13:30:00.048	GOOG	720.92	100
4	2016-05-25 13:30:00.048	AAPL	98.00	100

In [136]: quotes

Out[136]:

	time	ticker	bid	ask
0	2016-05-25 13:30:00.023	GOOG	720.50	720.93
1	2016-05-25 13:30:00.023	MSFT	51.95	51.96
2	2016-05-25 13:30:00.030	MSFT	51.97	51.98
3	2016-05-25 13:30:00.041	MSFT	51.99	52.00
4	2016-05-25 13:30:00.048	GOOG	720.50	720.93
5	2016-05-25 13:30:00.049	AAPL	97.99	98.01
6	2016-05-25 13:30:00.072	GOOG	720.50	720.88
7	2016-05-25 13:30:00.075	MSFT	52.01	52.03

By default we are taking the asof of the quotes.

```

In [137]: pd.merge_asof(trades, quotes,
.....:          on='time',
.....:
```

(continues on next page)

(continued from previous page)

.....:	by='ticker')
Out[137]:	
0	time ticker price quantity bid ask
2016-05-25 13:30:00.023	MSFT 51.95 75 51.95 51.96
1	2016-05-25 13:30:00.038 MSFT 51.95 155 51.97 51.98
2	2016-05-25 13:30:00.048 GOOG 720.77 100 720.50 720.93
3	2016-05-25 13:30:00.048 GOOG 720.92 100 720.50 720.93
4	2016-05-25 13:30:00.048 AAPL 98.00 100 NaN NaN

We only asof within 2ms between the quote time and the trade time.

In [138]:	pd.merge_asof(trades, quotes,
.....:	on='time',
.....:	by='ticker',
.....:	tolerance=pd.Timedelta('2ms'))
Out[138]:	
0	time ticker price quantity bid ask
2016-05-25 13:30:00.023	MSFT 51.95 75 51.95 51.96
1	2016-05-25 13:30:00.038 MSFT 51.95 155 NaN NaN

3.5 Reshaping and pivot tables

3.5.1 Reshaping by pivoting DataFrame objects

Data is often stored in so-called “stacked” or “record” format:

```
In [1]: df
Out[1]:
      date variable    value
0  2000-01-03        A  0.259126
1  2000-01-04        A  0.774683
2  2000-01-05        A  0.713390
3  2000-01-03        B -0.837638
4  2000-01-04        B  0.064089
5  2000-01-05        B -0.034934
6  2000-01-03        C -0.452395
7  2000-01-04        C  2.488398
8  2000-01-05        C  1.429389
9  2000-01-03        D  0.547623
10 2000-01-04        D  0.008959
11 2000-01-05        D  1.097237
```

For the curious here is how the above DataFrame was created:

```
import pandas._testing as tm

tm.N = 3

def unpivot(frame):
    N, K = frame.shape
    data = {'value': frame.to_numpy().ravel('F'),
            'variable': np.asarray(frame.columns).repeat(N),
            'date': np.tile(np.asarray(frame.index), K)}
```

(continues on next page)

(continued from previous page)

```
return pd.DataFrame(data, columns=['date', 'variable', 'value'])

df = unpivot(tm.makeTimeDataFrame())
```

To select out everything for variable A we could do:

In [2]:	df[df['variable'] == 'A']																
Out [2]:	<table border="1"> <thead> <tr> <th></th> <th>date</th> <th>variable</th> <th>value</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>2000-01-03</td> <td>A</td> <td>0.259126</td> </tr> <tr> <td>1</td> <td>2000-01-04</td> <td>A</td> <td>0.774683</td> </tr> <tr> <td>2</td> <td>2000-01-05</td> <td>A</td> <td>0.713390</td> </tr> </tbody> </table>		date	variable	value	0	2000-01-03	A	0.259126	1	2000-01-04	A	0.774683	2	2000-01-05	A	0.713390
	date	variable	value														
0	2000-01-03	A	0.259126														
1	2000-01-04	A	0.774683														
2	2000-01-05	A	0.713390														

But suppose we wish to do time series operations with the variables. A better representation would be where the columns are the unique variables and an index of dates identifies individual observations. To reshape the data into this form, we use the DataFrame.pivot() method (also implemented as a top level function `pivot()`):

In [3]:	df.pivot(index='date', columns='variable', values='value')																								
Out [3]:	<table border="1"> <thead> <tr> <th></th> <th>variable</th> <th>A</th> <th>B</th> <th>C</th> <th>D</th> </tr> </thead> <tbody> <tr> <td>date</td> <td>2000-01-03</td> <td>0.259126</td> <td>-0.837638</td> <td>-0.452395</td> <td>0.547623</td> </tr> <tr> <td>2000-01-04</td> <td>0.774683</td> <td>0.064089</td> <td>2.488398</td> <td>0.008959</td> <td></td> </tr> <tr> <td>2000-01-05</td> <td>0.713390</td> <td>-0.034934</td> <td>1.429389</td> <td>1.097237</td> <td></td> </tr> </tbody> </table>		variable	A	B	C	D	date	2000-01-03	0.259126	-0.837638	-0.452395	0.547623	2000-01-04	0.774683	0.064089	2.488398	0.008959		2000-01-05	0.713390	-0.034934	1.429389	1.097237	
	variable	A	B	C	D																				
date	2000-01-03	0.259126	-0.837638	-0.452395	0.547623																				
2000-01-04	0.774683	0.064089	2.488398	0.008959																					
2000-01-05	0.713390	-0.034934	1.429389	1.097237																					

If the values argument is omitted, and the input DataFrame has more than one column of values which are not used as column or index inputs to pivot, then the resulting “pivoted” DataFrame will have *hierarchical columns* whose topmost level indicates the respective value column:

In [4]:	df['value2'] = df['value'] * 2																																							
In [5]:	pivoted = df.pivot(index='date', columns='variable')																																							
In [6]:	pivoted																																							
Out [6]:	<table border="1"> <thead> <tr> <th></th> <th>variable</th> <th>A</th> <th>B</th> <th>C</th> <th>D</th> <th>A</th> <th>B</th> <th>C</th> </tr> </thead> <tbody> <tr> <td>date</td> <td>2000-01-03</td> <td>0.259126</td> <td>-0.837638</td> <td>-0.452395</td> <td>0.547623</td> <td>0.518252</td> <td>-1.675276</td> <td>-0.904790</td> <td>1.</td> </tr> <tr> <td>2000-01-04</td> <td>0.774683</td> <td>0.064089</td> <td>2.488398</td> <td>0.008959</td> <td>1.549366</td> <td>0.128178</td> <td>4.976796</td> <td>0.</td> <td></td> </tr> <tr> <td>2000-01-05</td> <td>0.713390</td> <td>-0.034934</td> <td>1.429389</td> <td>1.097237</td> <td>1.426780</td> <td>-0.069868</td> <td>2.858779</td> <td>2.</td> <td></td> </tr> </tbody> </table>		variable	A	B	C	D	A	B	C	date	2000-01-03	0.259126	-0.837638	-0.452395	0.547623	0.518252	-1.675276	-0.904790	1.	2000-01-04	0.774683	0.064089	2.488398	0.008959	1.549366	0.128178	4.976796	0.		2000-01-05	0.713390	-0.034934	1.429389	1.097237	1.426780	-0.069868	2.858779	2.	
	variable	A	B	C	D	A	B	C																																
date	2000-01-03	0.259126	-0.837638	-0.452395	0.547623	0.518252	-1.675276	-0.904790	1.																															
2000-01-04	0.774683	0.064089	2.488398	0.008959	1.549366	0.128178	4.976796	0.																																
2000-01-05	0.713390	-0.034934	1.429389	1.097237	1.426780	-0.069868	2.858779	2.																																

You can then select subsets from the pivoted DataFrame:

In [7]:	pivoted['value2']												
Out [7]:	<table border="1"> <thead> <tr> <th></th> <th>variable</th> <th>A</th> <th>B</th> <th>C</th> <th>D</th> </tr> </thead> <tbody> <tr> <td>date</td> <td>2000-01-03</td> <td>0.518252</td> <td>-1.675276</td> <td>-0.904790</td> <td>1.095246</td> </tr> </tbody> </table>		variable	A	B	C	D	date	2000-01-03	0.518252	-1.675276	-0.904790	1.095246
	variable	A	B	C	D								
date	2000-01-03	0.518252	-1.675276	-0.904790	1.095246								

(continues on next page)

(continued from previous page)

2000-01-04	1.549366	0.128178	4.976796	0.017919
2000-01-05	1.426780	-0.069868	2.858779	2.194473

Note that this returns a view on the underlying data in the case where the data are homogeneously-typed.

Note: `pivot()` will error with a `ValueError`: Index contains duplicate entries, cannot reshape if the index/column pair is not unique. In this case, consider using `pivot_table()` which is a generalization of pivot that can handle duplicate values for one index/column pair.

3.5.2 Reshaping by stacking and unstacking

Closely related to the `pivot()` method are the related `stack()` and `unstack()` methods available on Series and DataFrame. These methods are designed to work together with MultiIndex objects (see the section on [hierarchical indexing](#)). Here are essentially what these methods do:

- `stack`: “pivot” a level of the (possibly hierarchical) column labels, returning a `DataFrame` with an index with a new inner-most level of row labels.
 - `unstack`: (inverse operation of `stack`) “pivot” a level of the (possibly hierarchical) row index to the column axis, producing a reshaped `DataFrame` with a new inner-most level of column labels.

Unstack

The clearest way to explain is by example. Let's take a prior example data set from the hierarchical indexing section:

```
In [8]: tuples = list(zip(*[['bar', 'bar', 'baz', 'baz',
...:                   'foo', 'foo', 'qux', 'qux'],
...:                   ['one', 'two', 'one', 'two',
...:                   'one', 'two', 'one', 'two']]))

In [9]: index = pd.MultiIndex.from_tuples(tuples, names=['first', 'second'])

In [10]: df = pd.DataFrame(np.random.randn(8, 2), index=index, columns=['A', 'B'])

In [11]: df2 = df[:4]

In [12]: df2
Out[12]:
          A         B
first second
bar   one    -1.427767  1.011174
      two    -0.227837  0.260297
baz   one    -0.664499 -1.085553
      two    -1.392521 -0.426500
```

The `stack` function “compresses” a level in the `DataFrame`'s columns to produce either:

- A `Series`, in the case of a simple column Index.
- A `DataFrame`, in the case of a `MultiIndex` in the columns.

If the columns have a `MultiIndex`, you can choose which level to stack. The stacked level becomes the new lowest level in a `MultiIndex` on the columns:

```
In [13]: stacked = df2.stack()
```

```
In [14]: stacked
```

```
Out[14]:
```

	first	second	A	B
bar	one	A	-1.427767	1.011174
		B		
	two	A	-0.227837	0.260297
		B		
baz	one	A	-0.664499	-1.085553
		B		
	two	A	-1.392521	-0.426500
		B		

```
dtype: float64
```

With a “stacked” DataFrame or Series (having a MultiIndex as the index), the inverse operation of stack is unstack, which by default unstacks the **last level**:

```
In [15]: stacked.unstack()
```

```
Out[15]:
```

	first	second	A	B
bar	one	A	-1.427767	1.011174
		two	-0.227837	0.260297
baz	one	A	-0.664499	-1.085553
		two	-1.392521	-0.426500

```
In [16]: stacked.unstack(1)
```

```
Out[16]:
```

	second	one	two	
bar	one	A	-1.427767	-0.227837
		B	1.011174	0.260297
baz	one	A	-0.664499	-1.392521
		B	-1.085553	-0.426500

```
In [17]: stacked.unstack(0)
```

```
Out[17]:
```

	first	bar	baz	
one	one	A	-1.427767	-0.664499
		B	1.011174	-1.085553
two	one	A	-0.227837	-1.392521
		B	0.260297	-0.426500

Unstack(1)

If the indexes have names, you can use the level names instead of specifying the level numbers:

```
In [18]: stacked.unstack('second')
Out[18]:
second      one      two
first
bar    A -1.427767 -0.227837
        B  1.011174  0.260297
baz    A -0.664499 -1.392521
        B -1.085553 -0.426500
```

Unstack(0)

Notice that the `stack` and `unstack` methods implicitly sort the index levels involved. Hence a call to `stack` and then `unstack`, or vice versa, will result in a **sorted** copy of the original `DataFrame` or `Series`:

```
In [19]: index = pd.MultiIndex.from_product([[2, 1], ['a', 'b']])
In [20]: df = pd.DataFrame(np.random.randn(4), index=index, columns=['A'])
In [21]: df
Out[21]:
          A
2 a -1.727109
      b -1.966122
1 a -0.004308
      b  0.627249

In [22]: all(df.unstack().stack() == df.sort_index())
Out[22]: True
```

The above code will raise a `TypeError` if the call to `sort_index` is removed.

Multiple levels

You may also stack or unstack more than one level at a time by passing a list of levels, in which case the end result is as if each level in the list were processed individually.

```
In [23]: columns = pd.MultiIndex.from_tuples([
.....:     ('A', 'cat', 'long'), ('B', 'cat', 'long'),
.....:     ('A', 'dog', 'short'), ('B', 'dog', 'short')],
.....:     names=['exp', 'animal', 'hair_length']
.....: )
.....:
```

(continues on next page)

(continued from previous page)

```
In [24]: df = pd.DataFrame(np.random.randn(4, 4), columns=columns)
```

```
In [25]: df
```

```
Out[25]:
```

	A	B	A	B
exp				
animal	cat	cat	dog	dog
hair_length	long	long	short	short
0	-2.260817	0.023953	-1.328037	-0.091360
1	-0.063483	0.691641	1.062240	-1.912934
2	-0.967661	1.438160	1.796396	0.364482
3	0.384514	0.774313	-1.215737	1.533214

```
In [26]: df.stack(level=['animal', 'hair_length'])
```

```
Out[26]:
```

		A	B
exp			
	animal hair_length		
0	cat long	-2.260817	0.023953
	dog short	-1.328037	-0.091360
1	cat long	-0.063483	0.691641
	dog short	1.062240	-1.912934
2	cat long	-0.967661	1.438160
	dog short	1.796396	0.364482
3	cat long	0.384514	0.774313
	dog short	-1.215737	1.533214

The list of levels can contain either level names or level numbers (but not a mixture of the two).

```
# df.stack(level=['animal', 'hair_length'])
# from above is equivalent to:
```

```
In [27]: df.stack(level=[1, 2])
```

```
Out[27]:
```

		A	B
exp			
	animal hair_length		
0	cat long	-2.260817	0.023953
	dog short	-1.328037	-0.091360
1	cat long	-0.063483	0.691641
	dog short	1.062240	-1.912934
2	cat long	-0.967661	1.438160
	dog short	1.796396	0.364482
3	cat long	0.384514	0.774313
	dog short	-1.215737	1.533214

Missing data

These functions are intelligent about handling missing data and do not expect each subgroup within the hierarchical index to have the same set of labels. They also can handle the index being unsorted (but you can make it sorted by calling `sort_index`, of course). Here is a more complex example:

```
In [28]: columns = pd.MultiIndex.from_tuples([('A', 'cat'), ('B', 'dog'),
.....:                                     ('B', 'cat'), ('A', 'dog')],
.....:                                     names=['exp', 'animal']))
```

```
In [29]: index = pd.MultiIndex.from_product([('bar', 'baz', 'foo', 'qux'),
.....:                                         ('one', 'two')]),
```

(continues on next page)

(continued from previous page)

```
....:                                         names=['first', 'second'])
....:

In [30]: df = pd.DataFrame(np.random.randn(8, 4), index=index, columns=columns)

In [31]: df2 = df.iloc[[0, 1, 2, 4, 5, 7]]

In [32]: df2
Out[32]:
exp          A          B          A
animal      cat        dog        cat        dog
first second
bar    one   -1.436953  0.561814 -0.346880 -0.546060
       two   -1.993054 -0.689365 -0.877031  1.507935
baz    one   -1.866380  0.043384  0.252683 -0.479004
foo    one   -1.613149 -0.622599  0.291003  0.792238
       two    0.807151 -0.758613 -2.393856  1.098272
qux    two   -0.411186  1.584705 -1.042868 -0.295906
```

As mentioned above, `stack` can be called with a `level` argument to select which level in the columns to stack:

```
In [33]: df2.stack('exp')
Out[33]:
animal          cat        dog
first second exp
bar    one   A   -1.436953 -0.546060
       two   B   -0.346880  0.561814
             A   -1.993054  1.507935
             B   -0.877031 -0.689365
baz    one   A   -1.866380 -0.479004
             B   0.252683  0.043384
foo    one   A   -1.613149  0.792238
             B   0.291003 -0.622599
       two   A   0.807151  1.098272
             B   -2.393856 -0.758613
qux    two   A   -0.411186 -0.295906
             B   -1.042868  1.584705
```

```
In [34]: df2.stack('animal')
Out[34]:
exp          A          B
first second animal
bar    one   cat   -1.436953 -0.346880
       two   dog   -0.546060  0.561814
             cat   -1.993054 -0.877031
             dog    1.507935 -0.689365
baz    one   cat   -1.866380  0.252683
             dog   -0.479004  0.043384
foo    one   cat   -1.613149  0.291003
             dog    0.792238 -0.622599
       two   cat    0.807151 -2.393856
             dog    1.098272 -0.758613
qux    two   cat   -0.411186 -1.042868
             dog   -0.295906  1.584705
```

Unstacking can result in missing values if subgroups do not have the same set of labels. By default, missing values will be replaced with the default fill value for that data type, `NaN` for float, `NaT` for datetimelike, etc. For integer types,

by default data will converted to float and missing values will be set to NaN.

```
In [35]: df3 = df.iloc[[0, 1, 4, 7], [1, 2]]  
  
In [36]: df3  
Out[36]:  
exp              B  
animal          dog      cat  
first second  
bar   one    0.561814 -0.346880  
      two   -0.689365 -0.877031  
foo   one   -0.622599  0.291003  
qux   two    1.584705 -1.042868  
  
In [37]: df3.unstack()  
Out[37]:  
exp              B  
animal          dog            cat  
second         one           two       one       two  
first  
bar    0.561814 -0.689365 -0.346880 -0.877031  
foo   -0.622599      NaN  0.291003      NaN  
qux     NaN  1.584705      NaN -1.042868
```

Alternatively, unstack takes an optional `fill_value` argument, for specifying the value of missing data.

```
In [38]: df3.unstack(fill_value=-1e9)  
Out[38]:  
exp              B  
animal          dog            cat  
second         one           two       one       two  
first  
bar    5.618142e-01 -6.893650e-01 -3.468802e-01 -8.770315e-01  
foo   -6.225992e-01 -1.0000000e+09  2.910029e-01 -1.0000000e+09  
qux   -1.000000e+09  1.584705e+00 -1.000000e+09 -1.042868e+00
```

With a MultiIndex

Unstacking when the columns are a MultiIndex is also careful about doing the right thing:

```
In [39]: df[:3].unstack(0)  
Out[39]:  
exp          A          B          A  
animal      cat        dog        cat        A  
first       bar       baz       bar       baz  
second  
one   -1.436953 -1.86638  0.561814  0.043384 -0.346880  0.252683 -0.546060 -0.479004  
two   -1.993054      NaN -0.689365      NaN -0.877031      NaN  1.507935      NaN  
  
In [40]: df2.unstack(1)  
Out[40]:  
exp          A          B          A  
animal      cat        dog        cat        A  
second      one       two       one       two  
first  
bar   -1.436953 -1.993054  0.561814 -0.689365 -0.346880 -0.877031 -0.546060  1.507935  
(continues on next page)
```

(continued from previous page)

baz	-1.866380	NaN	0.043384	NaN	0.252683	NaN	-0.479004	NaN
foo	-1.613149	0.807151	-0.622599	-0.758613	0.291003	-2.393856	0.792238	1.098272

3.5.3 Reshaping by Melt

Melt

The top-level `melt()` function and the corresponding `DataFrame.melt()` are useful to massage a `DataFrame` into a format where one or more columns are *identifier variables*, while all other columns, considered *measured variables*, are “unpivoted” to the row axis, leaving just two non-identifier columns, “variable” and “value”. The names of those columns can be customized by supplying the `var_name` and `value_name` parameters.

For instance,

```
In [41]: cheese = pd.DataFrame({'first': ['John', 'Mary'],
.....:                   'last': ['Doe', 'Bo'],
.....:                   'height': [5.5, 6.0],
.....:                   'weight': [130, 150]})

In [42]: cheese
Out[42]:
   first  last  height  weight
0   John   Doe     5.5     130
1   Mary    Bo     6.0     150

In [43]: cheese.melt(id_vars=['first', 'last'])
Out[43]:
   first  last  variable  value
0   John   Doe    height    5.5
1   Mary    Bo    height    6.0
2   John   Doe   weight  130.0
3   Mary    Bo   weight  150.0
```

(continues on next page)

(continued from previous page)

```
In [44]: cheese.melt(id_vars=['first', 'last'], var_name='quantity')
Out[44]:
   first last quantity  value
0  John   Doe    height  5.5
1  Mary   Bo    height  6.0
2  John   Doe   weight 130.0
3  Mary   Bo   weight 150.0
```

Another way to transform is to use the `wide_to_long()` panel data convenience function. It is less flexible than `melt()`, but more user-friendly.

```
In [45]: dft = pd.DataFrame({ "A1970": {0: "a", 1: "b", 2: "c"}, "A1980": {0: "d", 1: "e", 2: "f"}, "B1970": {0: 2.5, 1: 1.2, 2: .7}, "B1980": {0: 3.2, 1: 1.3, 2: .1}, "X": dict(zip(range(3), np.random.randn(3)))})
.....
In [46]: dft["id"] = dft.index
In [47]: dft
Out[47]:
   A1970  A1980  B1970  B1980      X  id
0       a      d    2.5    3.2 -2.013095  0
1       b      e    1.2    1.3 -1.711797  1
2       c      f    0.7    0.1  0.975018  2

In [48]: pd.wide_to_long(dft, ["A", "B"], i="id", j="year")
Out[48]:
      X  A     B
id year
0  1970 -2.013095  a  2.5
1  1970 -1.711797  b  1.2
2  1970  0.975018  c  0.7
0  1980 -2.013095  d  3.2
1  1980 -1.711797  e  1.3
2  1980  0.975018  f  0.1
```

3.5.4 Combining with stats and GroupBy

It should be no shock that combining `pivot` / `stack` / `unstack` with `GroupBy` and the basic Series and DataFrame statistical functions can produce some very expressive and fast data manipulations.

```
In [49]: df
Out[49]:
exp           A           B           A
animal        cat         dog        cat        dog
first second
bar  one    -1.436953  0.561814 -0.346880 -0.546060
      two    -1.993054 -0.689365 -0.877031  1.507935
baz  one    -1.866380  0.043384  0.252683 -0.479004
      two    -0.190425 -1.520207  1.697480  0.923916
foo  one    -1.613149 -0.622599  0.291003  0.792238
```

(continues on next page)

(continued from previous page)

```
two      0.807151 -0.758613 -2.393856  1.098272
qux    one     -0.168090 -0.243576  0.316513 -0.633213
       two     -0.411186  1.584705 -1.042868 -0.295906
```

In [50]: df.stack().mean(1).unstack()

Out[50]:

```
animal          cat      dog
first second
bar   one     -0.891917  0.007877
      two     -1.435043  0.409285
baz   one     -0.806849 -0.217810
      two     0.753528 -0.298146
foo   one     -0.661073  0.084819
      two     -0.793352  0.169830
qux   one     0.074211 -0.438394
      two     -0.727027  0.644399
```

same result, another way

In [51]: df.groupby(level=1, axis=1).mean()

Out[51]:

```
animal          cat      dog
first second
bar   one     -0.891917  0.007877
      two     -1.435043  0.409285
baz   one     -0.806849 -0.217810
      two     0.753528 -0.298146
foo   one     -0.661073  0.084819
      two     -0.793352  0.169830
qux   one     0.074211 -0.438394
      two     -0.727027  0.644399
```

In [52]: df.stack().groupby(level=1).mean()

Out[52]:

```
exp          A      B
second
one     -0.743827  0.031543
two      0.180838 -0.499969
```

In [53]: df.mean().unstack(0)

Out[53]:

```
exp          A      B
animal
cat     -0.859011 -0.262870
dog      0.296022 -0.205557
```

3.5.5 Pivot tables

While `pivot()` provides general purpose pivoting with various data types (strings, numerics, etc.), pandas also provides `pivot_table()` for pivoting with aggregation of numeric data.

The function `pivot_table()` can be used to create spreadsheet-style pivot tables. See the [cookbook](#) for some advanced strategies.

It takes a number of arguments:

- `data`: a DataFrame object.

- values: a column or a list of columns to aggregate.
- index: a column, Grouper, array which has the same length as data, or list of them. Keys to group by on the pivot table index. If an array is passed, it is being used as the same manner as column values.
- columns: a column, Grouper, array which has the same length as data, or list of them. Keys to group by on the pivot table column. If an array is passed, it is being used as the same manner as column values.
- aggfunc: function to use for aggregation, defaulting to numpy.mean.

Consider a data set like this:

```
In [54]: import datetime

In [55]: df = pd.DataFrame({'A': ['one', 'one', 'two', 'three'] * 6,
.....:                 'B': ['A', 'B', 'C'] * 8,
.....:                 'C': ['foo', 'foo', 'foo', 'bar', 'bar', 'bar'] * 4,
.....:                 'D': np.random.randn(24),
.....:                 'E': np.random.randn(24),
.....:                 'F': [datetime.datetime(2013, i, 1) for i in range(1, 13)]
.....:                  + [datetime.datetime(2013, i, 15) for i in range(1, 13)]})
.....:

In [56]: df
Out[56]:
   A    B    C      D      E           F
0  one   A  foo  1.772891 -1.594231 2013-01-01
1  one   B  foo  0.498050 -1.165583 2013-02-01
2  two   C  foo  0.476510  0.451407 2013-03-01
3  three  A  bar  0.877022 -1.724523 2013-04-01
4  one   B  bar -0.301831  2.097509 2013-05-01
5  one   C  bar -0.733711  1.078343 2013-06-01
6  two   A  foo  0.826360 -0.394125 2013-07-01
7  three  B  foo  0.466766 -0.726083 2013-08-01
8  one   C  foo  1.634589  0.490827 2013-09-01
9  one   A  bar  0.958132 -0.559443 2013-10-01
10  two   B  bar -0.970543 -0.395876 2013-11-01
11  three  C  bar -0.932172 -0.927091 2013-12-01
12  one   A  foo -1.273567 -0.417776 2013-01-15
13  one   B  foo  0.270030 -0.708679 2013-02-15
14  two   C  foo -1.388749 -1.557855 2013-03-15
15  three  A  bar  2.090035 -1.742504 2013-04-15
16  one   B  bar -0.815984 -0.201498 2013-05-15
17  one   C  bar -0.020855  0.070382 2013-06-15
18  two   A  foo -0.108292 -0.749683 2013-07-15
19  three  B  foo  0.093700  1.434318 2013-08-15
20  one   C  foo -0.851281  1.226799 2013-09-15
21  one   A  bar -2.154727 -0.706492 2013-10-15
22  two   B  bar -0.120914  0.299114 2013-11-15
23  three  C  bar -0.976377 -0.081937 2013-12-15
```

We can produce pivot tables from this data very easily:

```
In [57]: pd.pivot_table(df, values='D', index=['A', 'B'], columns=['C'])
Out[57]:
C
  bar    foo
A
one
  A -0.598297  0.249662
      B -0.558907  0.384040
```

(continues on next page)

(continued from previous page)

```
C -0.377283  0.391654
three A  1.483528      NaN
       B      NaN  0.280233
       C -0.954274      NaN
two   A      NaN  0.359034
      B -0.545728      NaN
      C      NaN -0.456119

In [58]: pd.pivot_table(df, values='D', index=['B'], columns=['A', 'C'], aggfunc=np.sum)
Out[58]:
A      one            three            two
C    bar      foo      bar      foo      bar      foo
B
A -1.196595  0.499324  2.967057      NaN      NaN  0.718067
B -1.117815  0.768081      NaN  0.560466 -1.091457      NaN
C -0.754566  0.783308 -1.908549      NaN      NaN -0.912238

In [59]: pd.pivot_table(df, values=['D', 'E'], index=['B'], columns=['A', 'C'],
....:                               aggfunc=np.sum)
....:
Out[59]:
          D                           E
A      one            three            two      one
C    bar      foo      bar      foo      bar      foo
B
A -1.196595  0.499324  2.967057      NaN      NaN  0.718067 -1.265936 -2.012007 -3.
B -1.117815  0.768081      NaN  0.560466 -1.091457      NaN  1.896010 -1.874262
C -0.754566  0.783308 -1.908549      NaN      NaN -0.912238  1.148725  1.717626 -1.
B -0.09028      NaN      NaN -1.106447
```

The result object is a DataFrame having potentially hierarchical indexes on the rows and columns. If the values column name is not given, the pivot table will include all of the data that can be aggregated in an additional level of hierarchy in the columns:

```
In [60]: pd.pivot_table(df, index=['A', 'B'], columns=['C'])
Out[60]:
          D                           E
C      bar      foo      bar      foo
A      B
one   A -0.598297  0.249662 -0.632968 -1.006004
      B -0.558907  0.384040  0.948005 -0.937131
      C -0.377283  0.391654  0.574362  0.858813
three A  1.483528      NaN -1.733513      NaN
      B      NaN  0.280233      NaN  0.354117
      C -0.954274      NaN -0.504514      NaN
two   A      NaN  0.359034      NaN -0.571904
      B -0.545728      NaN -0.048381      NaN
      C      NaN -0.456119      NaN -0.553224
```

Also, you can use Grouper for index and columns keywords. For detail of Grouper, see [Grouping with a](#)

Grouper specification.

```
In [61]: pd.pivot_table(df, values='D', index=pd.Grouper(freq='M', key='F'),
....:                      columns='C')
....:
Out[61]:
C           bar      foo
F
2013-01-31     NaN  0.249662
2013-02-28     NaN  0.384040
2013-03-31     NaN -0.456119
2013-04-30  1.483528      NaN
2013-05-31 -0.558907      NaN
2013-06-30 -0.377283      NaN
2013-07-31     NaN  0.359034
2013-08-31     NaN  0.280233
2013-09-30     NaN  0.391654
2013-10-31 -0.598297      NaN
2013-11-30 -0.545728      NaN
2013-12-31 -0.954274      NaN
```

You can render a nice output of the table omitting the missing values by calling `to_string` if you wish:

```
In [62]: table = pd.pivot_table(df, index=['A', 'B'], columns=['C'])

In [63]: print(table.to_string(na_rep=' '))
          D           E
          bar      foo    bar      foo
C
A   B
one  A -0.598297  0.249662 -0.632968 -1.006004
     B -0.558907  0.384040  0.948005 -0.937131
     C -0.377283  0.391654  0.574362  0.858813
three A  1.483528           -1.733513
       B           0.280233           0.354117
       C -0.954274           -0.504514
two   A           0.359034           -0.571904
     B -0.545728           -0.048381
     C           -0.456119           -0.553224
```

Note that `pivot_table` is also available as an instance method on `DataFrame`, i.e. `DataFrame.pivot_table()`.

Adding margins

If you pass `margins=True` to `pivot_table`, special All columns and rows will be added with partial group aggregates across the categories on the rows and columns:

```
In [64]: df.pivot_table(index=['A', 'B'], columns='C', margins=True, aggfunc=np.std)
Out[64]:
          D           E
          bar      foo    bar      foo    All
C
A   B
one  A  2.201124  2.154171  1.844310  0.103979  0.831880  0.529777
     B  0.363561  0.161235  0.590854  1.625643  0.323080  1.449234
     C  0.504065  1.757775  1.145298  0.712737  0.520411  0.535329
three A  0.857730      NaN  0.857730  0.012714      NaN  0.012714
       B      NaN  0.263797  0.263797      NaN  1.527634  1.527634
```

(continues on next page)

3.5.6 Cross tabulations

Use `crosstab()` to compute a cross-tabulation of two (or more) factors. By default `crosstab` computes a frequency table of the factors unless an array of values and an aggregation function are passed.

It takes a number of arguments

- `index`: array-like, values to group by in the rows.
- `columns`: array-like, values to group by in the columns.
- `values`: array-like, optional, array of values to aggregate according to the factors.
- `aggfunc`: function, optional, If no values array is passed, computes a frequency table.
- `rownames`: sequence, default `None`, must match number of row arrays passed.
- `colnames`: sequence, default `None`, if passed, must match number of column arrays passed.
- `margins`: boolean, default `False`, Add row/column margins (subtotals)
- `normalize`: boolean, {‘all’, ‘index’, ‘columns’}, or {0,1}, default `False`. Normalize by dividing all values by the sum of values.

Any `Series` passed will have their name attributes used unless row or column names for the cross-tabulation are specified

For example:

```
In [65]: foo, bar, dull, shiny, one, two = 'foo', 'bar', 'dull', 'shiny', 'one', 'two'

In [66]: a = np.array([foo, foo, bar, bar, foo, foo], dtype=object)

In [67]: b = np.array([one, one, two, one, two, one], dtype=object)

In [68]: c = np.array([dull, dull, shiny, dull, dull, shiny], dtype=object)

In [69]: pd.crosstab(a, [b, c], rownames=['a'], colnames=['b', 'c'])

Out[69]:
b   one      two
c  dull shiny dull shiny
a
bar    1     0     0     1
foo    2     1     1     0
```

If `crosstab` receives only two `Series`, it will provide a frequency table.

```
In [70]: df = pd.DataFrame({'A': [1, 2, 2, 2, 2], 'B': [3, 3, 4, 4, 4],
.....:             'C': [1, 1, np.nan, 1, 1]})

In [71]: df
Out[71]:
```

(continues on next page)

(continued from previous page)

```
A   B   C
0   1   3   1.0
1   2   3   1.0
2   2   4   NaN
3   2   4   1.0
4   2   4   1.0
```

In [72]: pd.crosstab(df['A'], df['B'])

Out[72]:

```
B   3   4
A
1   1   0
2   1   3
```

Any input passed containing `Categorical` data will have **all** of its categories included in the cross-tabulation, even if the actual data does not contain any instances of a particular category.

In [73]: foo = pd.Categorical(['a', 'b'], categories=['a', 'b', 'c'])

In [74]: bar = pd.Categorical(['d', 'e'], categories=['d', 'e', 'f'])

In [75]: pd.crosstab(foo, bar)

Out[75]:

```
col_0  d   e
row_0
a      1   0
b      0   1
```

Normalization

Frequency tables can also be normalized to show percentages rather than counts using the `normalize` argument:

In [76]: pd.crosstab(df['A'], df['B'], normalize=True)

Out[76]:

```
B   3   4
A
1  0.2  0.0
2  0.2  0.6
```

`normalize` can also normalize values within each row or within each column:

In [77]: pd.crosstab(df['A'], df['B'], normalize='columns')

Out[77]:

```
B   3   4
A
1  0.5  0.0
2  0.5  1.0
```

`crosstab` can also be passed a third `Series` and an aggregation function (`aggfunc`) that will be applied to the values of the third `Series` within each group defined by the first two `Series`:

In [78]: pd.crosstab(df['A'], df['B'], values=df['C'], aggfunc=np.sum)

Out[78]:

```
B   3   4
A
```

(continues on next page)

(continued from previous page)

```
1 1.0  NaN
2 1.0  2.0
```

Adding margins

Finally, one can also add margins or normalize this output.

```
In [79]: pd.crosstab(df['A'], df['B'], values=df['C'], aggfunc=np.sum, normalize=True,
....:                         margins=True)
....:
Out[79]:
B      3     4    All
A
1    0.25  0.0  0.25
2    0.25  0.5  0.75
All   0.50  0.5  1.00
```

3.5.7 Tiling

The `cut()` function computes groupings for the values of the input array and is often used to transform continuous variables to discrete or categorical variables:

```
In [80]: ages = np.array([10, 15, 13, 12, 23, 25, 28, 59, 60])

In [81]: pd.cut(ages, bins=3)
Out[81]:
[(9.95, 26.667], (9.95, 26.667], (9.95, 26.667], (9.95, 26.667], (9.95, 26.667], (9.95, 26.667], (9.
˓→95, 26.667], (26.667, 43.333], (43.333, 60.0], (43.333, 60.0]]
Categories (3, interval[float64]): [(9.95, 26.667] < (26.667, 43.333] < (43.333, 60.
˓→0]]
```

If the `bins` keyword is an integer, then equal-width bins are formed. Alternatively we can specify custom bin-edges:

```
In [82]: c = pd.cut(ages, bins=[0, 18, 35, 70])

In [83]: c
Out[83]:
[(0, 18], (0, 18], (0, 18], (0, 18], (18, 35], (18, 35], (18, 35], (35, 70], (35, 70]]
Categories (3, interval[int64]): [(0, 18] < (18, 35] < (35, 70]]
```

If the `bins` keyword is an `IntervalIndex`, then these will be used to bin the passed data.:

```
pd.cut([25, 20, 50], bins=c.categories)
```

3.5.8 Computing indicator / dummy variables

To convert a categorical variable into a “dummy” or “indicator” DataFrame, for example a column in a DataFrame (a Series) which has k distinct values, can derive a DataFrame containing k columns of 1s and 0s using `get_dummies()`:

```
In [84]: df = pd.DataFrame({'key': list('bbacab'), 'data1': range(6)})  
  
In [85]: pd.get_dummies(df['key'])  
Out[85]:  
   a   b   c  
0  0   1   0  
1  0   1   0  
2  1   0   0  
3  0   0   1  
4  1   0   0  
5  0   1   0
```

Sometimes it’s useful to prefix the column names, for example when merging the result with the original DataFrame:

```
In [86]: dummies = pd.get_dummies(df['key'], prefix='key')  
  
In [87]: dummies  
Out[87]:  
   key_a  key_b  key_c  
0      0      1      0  
1      0      1      0  
2      1      0      0  
3      0      0      1  
4      1      0      0  
5      0      1      0  
  
In [88]: df[['data1']].join(dummies)  
Out[88]:  
   data1  key_a  key_b  key_c  
0      0      0      1      0  
1      1      0      1      0  
2      2      1      0      0  
3      3      0      0      1  
4      4      1      0      0  
5      5      0      1      0
```

This function is often used along with discretization functions like `cut`:

```
In [89]: values = np.random.randn(10)  
  
In [90]: values  
Out[90]:  
array([-0.7350435,  1.42920375, -1.11519984, -0.97015174, -1.19270064,  
       0.02125661, -0.20556342, -0.66677255,  2.12277401, -0.10814128])  
  
In [91]: bins = [0, 0.2, 0.4, 0.6, 0.8, 1]
```

(continues on next page)

(continued from previous page)

```
In [92]: pd.get_dummies(pd.cut(values, bins))
Out[92]:
(0.0, 0.2] (0.2, 0.4] (0.4, 0.6] (0.6, 0.8] (0.8, 1.0]
0          0          0          0          0          0
1          0          0          0          0          0
2          0          0          0          0          0
3          0          0          0          0          0
4          0          0          0          0          0
5          1          0          0          0          0
6          0          0          0          0          0
7          0          0          0          0          0
8          0          0          0          0          0
9          0          0          0          0          0
```

See also `Series.str.get_dummies`.

`get_dummies()` also accepts a DataFrame. By default all categorical variables (categorical in the statistical sense, those with `object` or `categorical` dtype) are encoded as dummy variables.

```
In [93]: df = pd.DataFrame({'A': ['a', 'b', 'a'], 'B': ['c', 'c', 'b'],
....:                  'C': [1, 2, 3]})
....:

In [94]: pd.get_dummies(df)
Out[94]:
   C  A_a  A_b  B_b  B_c
0  1    1    0    0    1
1  2    0    1    0    1
2  3    1    0    1    0
```

All non-object columns are included untouched in the output. You can control the columns that are encoded with the `columns` keyword.

```
In [95]: pd.get_dummies(df, columns=['A'])
Out[95]:
   B  C  A_a  A_b
0  c  1    1    0
1  c  2    0    1
2  b  3    1    0
```

Notice that the `B` column is still included in the output, it just hasn't been encoded. You can drop `B` before calling `get_dummies` if you don't want to include it in the output.

As with the Series version, you can pass values for the `prefix` and `prefix_sep`. By default the column name is used as the prefix, and `_` as the prefix separator. You can specify `prefix` and `prefix_sep` in 3 ways:

- string: Use the same value for `prefix` or `prefix_sep` for each column to be encoded.
- list: Must be the same length as the number of columns being encoded.
- dict: Mapping column name to prefix.

```
In [96]: simple = pd.get_dummies(df, prefix='new_prefix')

In [97]: simple
Out[97]:
   C  new_prefix_a  new_prefix_b  new_prefix_b  new_prefix_c
0  1            1            0            0            1
```

(continues on next page)

(continued from previous page)

1	2	0	1	0	1
2	3	1	0	1	0
In [98]: <code>from_list = pd.get_dummies(df, prefix=['from_A', 'from_B'])</code>					
In [99]: <code>from_list</code>					
Out[99]:					
0	1	from_A_a	from_A_b	from_B_b	from_B_c
1	2	1	0	0	1
2	3	0	1	0	1
In [100]: <code>from_dict = pd.get_dummies(df, prefix={'B': 'from_B', 'A': 'from_A'})</code>					
In [101]: <code>from_dict</code>					
Out[101]:					
0	1	from_A_a	from_A_b	from_B_b	from_B_c
1	2	1	0	0	1
2	3	0	1	0	1

Sometimes it will be useful to only keep k-1 levels of a categorical variable to avoid collinearity when feeding the result to statistical models. You can switch to this mode by turn on `drop_first`.

In [102]: <code>s = pd.Series(list('abcaa'))</code>					
In [103]: <code>pd.get_dummies(s)</code>					
Out[103]:					
0	a	b	c		
1	1	0	0		
2	0	1	0		
3	0	0	1		
4	1	0	0		
In [104]: <code>pd.get_dummies(s, drop_first=True)</code>					
Out[104]:					
0	b	c			
1	0	0			
2	1	0			
3	0	1			
4	0	0			

When a column contains only one level, it will be omitted in the result.

In [105]: <code>df = pd.DataFrame({'A': list('aaaaa'), 'B': list('ababc')})</code>					
In [106]: <code>pd.get_dummies(df)</code>					
Out[106]:					
0	A_a	B_a	B_b	B_c	
1	1	1	0	0	
2	1	0	1	0	
3	1	1	0	0	
4	1	0	1	0	

(continues on next page)

(continued from previous page)

```
In [107]: pd.get_dummies(df, drop_first=True)
Out[107]:
   B_b  B_c
0    0    0
1    1    0
2    0    0
3    1    0
4    0    1
```

By default new columns will have `np.uint8` dtype. To choose another dtype, use the `dtype` argument:

```
In [108]: df = pd.DataFrame({'A': list('abc'), 'B': [1.1, 2.2, 3.3]})

In [109]: pd.get_dummies(df, dtype=bool).dtypes
Out[109]:
B      float64
A_a     bool
A_b     bool
A_c     bool
dtype: object
```

New in version 0.23.0.

3.5.9 Factorizing values

To encode 1-d values as an enumerated type use `factorize()`:

```
In [110]: x = pd.Series(['A', 'A', np.nan, 'B', 3.14, np.inf])

In [111]: x
Out[111]:
0      A
1      A
2    NaN
3      B
4    3.14
5    inf
dtype: object

In [112]: labels, uniques = pd.factorize(x)

In [113]: labels
Out[113]: array([0, 0, -1, 1, 2, 3])

In [114]: uniques
Out[114]: Index(['A', 'B', 3.14, inf], dtype='object')
```

Note that `factorize` is similar to `numpy.unique`, but differs in its handling of `NaN`:

Note: The following `numpy.unique` will fail under Python 3 with a `TypeError` because of an ordering bug. See also [here](#).

```
In [1]: x = pd.Series(['A', 'A', np.nan, 'B', 3.14, np.inf])
In [2]: pd.factorize(x, sort=True)
Out[2]:
(array([ 2,  2, -1,  3,  0,  1]),
 Index([3.14, inf, 'A', 'B'], dtype='object'))

In [3]: np.unique(x, return_inverse=True)[::-1]
Out[3]: (array([3, 3, 0, 4, 1, 2]), array([nan, 3.14, inf, 'A', 'B'], dtype=object))
```

Note: If you just want to handle one column as a categorical variable (like R's factor), you can use `df["cat_col"] = pd.Categorical(df["col"])` or `df["cat_col"] = df["col"].astype("category")`. For full docs on `Categorical`, see the [Categorical introduction](#) and the [API documentation](#).

3.5.10 Examples

In this section, we will review frequently asked questions and examples. The column names and relevant column values are named to correspond with how this DataFrame will be pivoted in the answers below.

```
In [115]: np.random.seed([3, 1415])

In [116]: n = 20

In [117]: cols = np.array(['key', 'row', 'item', 'col'])

In [118]: df = cols + pd.DataFrame((np.random.randint(5, size=(n, 4))
.....:                         // [2, 1, 2, 1]).astype(str))
.....:

In [119]: df.columns = cols

In [120]: df = df.join(pd.DataFrame(np.random.rand(n, 2).round(2)).add_prefix('val'))

In [121]: df
Out[121]:
   key    row    item    col    val0    val1
0  key0  row3  item1  col3  0.81  0.04
1  key1  row2  item1  col2  0.44  0.07
2  key1  row0  item1  col0  0.77  0.01
3  key0  row4  item0  col2  0.15  0.59
4  key1  row0  item2  col1  0.81  0.64
5  key1  row2  item2  col4  0.13  0.88
6  key2  row4  item1  col3  0.88  0.39
7  key1  row4  item1  col1  0.10  0.07
8  key1  row0  item2  col4  0.65  0.02
9  key1  row2  item0  col2  0.35  0.61
10 key2  row0  item2  col1  0.40  0.85
11 key2  row4  item1  col2  0.64  0.25
12 key0  row2  item2  col3  0.50  0.44
13 key0  row4  item1  col4  0.24  0.46
14 key1  row3  item2  col3  0.28  0.11
15 key0  row3  item1  col1  0.31  0.23
16 key0  row0  item2  col3  0.86  0.01
17 key0  row4  item0  col3  0.64  0.21
```

(continues on next page)

(continued from previous page)

```
18  key2  row2  item2  col0  0.13  0.45
19  key0  row2  item0  col4  0.37  0.70
```

Pivoting with single aggregations

Suppose we wanted to pivot `df` such that the `col` values are columns, `row` values are the index, and the mean of `val0` are the values? In particular, the resulting DataFrame should look like:

col	col0	col1	col2	col3	col4
row					
row0	0.77	0.605	NaN	0.860	0.65
row2	0.13	NaN	0.395	0.500	0.25
row3	NaN	0.310	NaN	0.545	NaN
row4	NaN	0.100	0.395	0.760	0.24

This solution uses `pivot_table()`. Also note that `aggfunc='mean'` is the default. It is included here to be explicit.

```
In [122]: df.pivot_table(
.....:     values='val0', index='row', columns='col', aggfunc='mean')
.....:
Out[122]:
col  col0  col1  col2  col3  col4
row
row0  0.77  0.605  NaN  0.860  0.65
row2  0.13  NaN  0.395  0.500  0.25
row3  NaN  0.310  NaN  0.545  NaN
row4  NaN  0.100  0.395  0.760  0.24
```

Note that we can also replace the missing values by using the `fill_value` parameter.

```
In [123]: df.pivot_table(
.....:     values='val0', index='row', columns='col', aggfunc='mean', fill_value=0)
.....:
Out[123]:
col  col0  col1  col2  col3  col4
row
row0  0.77  0.605  0.000  0.860  0.65
row2  0.13  0.000  0.395  0.500  0.25
row3  0.00  0.310  0.000  0.545  0.00
row4  0.00  0.100  0.395  0.760  0.24
```

Also note that we can pass in other aggregation functions as well. For example, we can also pass in `sum`.

```
In [124]: df.pivot_table(
.....:     values='val0', index='row', columns='col', aggfunc='sum', fill_value=0)
.....:
Out[124]:
col  col0  col1  col2  col3  col4
row
row0  0.77  1.21  0.00  0.86  0.65
row2  0.13  0.00  0.79  0.50  0.50
row3  0.00  0.31  0.00  1.09  0.00
row4  0.00  0.10  0.79  1.52  0.24
```

Another aggregation we can do is calculate the frequency in which the columns and rows occur together a.k.a. “cross tabulation”. To do this, we can pass `size` to the `aggfunc` parameter.

```
In [125]: df.pivot_table(index='row', columns='col', fill_value=0, aggfunc='size')
Out[125]:
col  col0  col1  col2  col3  col4
row
row0    1     2     0     1     1
row2    1     0     2     1     2
row3    0     1     0     2     0
row4    0     1     2     2     1
```

Pivoting with multiple aggregations

We can also perform multiple aggregations. For example, to perform both a `sum` and mean, we can pass in a list to the `aggfunc` argument.

```
In [126]: df.pivot_table(
.....:     values='val0', index='row', columns='col', aggfunc=['mean', 'sum'])
.....:
Out[126]:
mean                                         sum
col  col0  col1  col2  col3  col4  col0  col1  col2  col3  col4
row
row0  0.77  0.605   NaN  0.860  0.65  0.77  1.21   NaN  0.86  0.65
row2  0.13   NaN  0.395  0.500  0.25  0.13   NaN  0.79  0.50  0.50
row3   NaN  0.310   NaN  0.545   NaN   NaN  0.31   NaN  1.09   NaN
row4   NaN  0.100  0.395  0.760  0.24   NaN  0.10  0.79  1.52  0.24
```

Note to aggregate over multiple value columns, we can pass in a list to the `values` parameter.

```
In [127]: df.pivot_table(
.....:     values=['val0', 'val1'], index='row', columns='col', aggfunc=['mean'])
.....:
Out[127]:
mean
val0                                         val1
col  col0  col1  col2  col3  col4  col0  col1  col2  col3  col4
row
row0  0.77  0.605   NaN  0.860  0.65  0.01  0.745   NaN  0.010  0.02
row2  0.13   NaN  0.395  0.500  0.25  0.45   NaN  0.34  0.440  0.79
row3   NaN  0.310   NaN  0.545   NaN   NaN  0.230   NaN  0.075   NaN
row4   NaN  0.100  0.395  0.760  0.24   NaN  0.070  0.42  0.300  0.46
```

Note to subdivide over multiple columns we can pass in a list to the `columns` parameter.

```
In [128]: df.pivot_table(
.....:     values=['val0'], index='row', columns=['item', 'col'], aggfunc=['mean'])
.....:
Out[128]:
mean
val0
item item0           item1           item2
col  col2  col3  col4  col0  col1  col2  col3  col4  col0  col1  col3  col4
row
row0   NaN   NaN   NaN  0.77   NaN   NaN   NaN   NaN   NaN  0.605  0.86  0.65
```

(continues on next page)

(continued from previous page)

row2	0.35	NaN	0.37	NaN	NaN	0.44	NaN	NaN	0.13	NaN	0.50	0.13
row3	NaN	NaN	NaN	NaN	0.31	NaN	0.81	NaN	NaN	NaN	0.28	NaN
row4	0.15	0.64	NaN	NaN	0.10	0.64	0.88	0.24	NaN	NaN	NaN	NaN

3.5.11 Exploding a list-like column

New in version 0.25.0.

Sometimes the values in a column are list-like.

```
In [129]: keys = ['panda1', 'panda2', 'panda3']

In [130]: values = [['eats', 'shoots'], ['shoots', 'leaves'], ['eats', 'leaves']]

In [131]: df = pd.DataFrame({'keys': keys, 'values': values})

In [132]: df
Out[132]:
   keys          values
0  panda1    [eats, shoots]
1  panda2  [shoots, leaves]
2  panda3    [eats, leaves]
```

We can ‘explode’ the values column, transforming each list-like to a separate row, by using `explode()`. This will replicate the index values from the original row:

```
In [133]: df['values'].explode()
Out[133]:
0      eats
0     shoots
1     shoots
1    leaves
2      eats
2    leaves
Name: values, dtype: object
```

You can also explode the column in the DataFrame.

```
In [134]: df.explode('values')
Out[134]:
   keys  values
0  panda1    eats
0  panda1   shoots
1  panda2   shoots
1  panda2   leaves
2  panda3    eats
2  panda3   leaves
```

`Series.explode()` will replace empty lists with `np.nan` and preserve scalar entries. The `dtype` of the resulting Series is always `object`.

```
In [135]: s = pd.Series([[1, 2, 3], 'foo', [], ['a', 'b']])
In [136]: s
Out[136]:
```

(continues on next page)

(continued from previous page)

```
0    [1, 2, 3]
1        foo
2        []
3    [a, b]
dtype: object

In [137]: s.explode()
Out[137]:
0      1
0      2
0      3
1    foo
2    NaN
3      a
3      b
dtype: object
```

Here is a typical usecase. You have comma separated strings in a column and want to expand this.

```
In [138]: df = pd.DataFrame([{'var1': 'a,b,c', 'var2': 1},
.....:                         {'var1': 'd,e,f', 'var2': 2}])
.....:

In [139]: df
Out[139]:
   var1  var2
0  a,b,c      1
1  d,e,f      2
```

Creating a long form DataFrame is now straightforward using explode and chained operations

```
In [140]: df.assign(var1=df.var1.str.split(',')).explode('var1')
Out[140]:
   var1  var2
0    a      1
0    b      1
0    c      1
1    d      2
1    e      2
1    f      2
```

{{ header }}

3.6 Working with text data

3.6.1 Text Data Types

New in version 1.0.0.

There are two ways to store text data in pandas:

1. `object`-dtype NumPy array.
2. `StringDtype` extension type.

We recommend using `StringDtype` to store text data.

Prior to pandas 1.0, `object` dtype was the only option. This was unfortunate for many reasons:

1. You can accidentally store a *mixture* of strings and non-strings in an `object` dtype array. It's better to have a dedicated dtype.
2. `object` dtype breaks dtype-specific operations like `DataFrame.select_dtypes()`. There isn't a clear way to select *just* text while excluding non-text but still `object`-dtype columns.
3. When reading code, the contents of an `object` dtype array is less clear than '`string`'.

Currently, the performance of `object` dtype arrays of strings and `arrays.StringArray` are about the same. We expect future enhancements to significantly increase the performance and lower the memory overhead of `StringArray`.

Warning: `StringArray` is currently considered experimental. The implementation and parts of the API may change without warning.

For backwards-compatibility, `object` dtype remains the default type we infer a list of strings to

```
In [1]: pd.Series(['a', 'b', 'c'])
Out[1]:
0    a
1    b
2    c
dtype: object
```

To explicitly request `string` dtype, specify the `dtype`

```
In [2]: pd.Series(['a', 'b', 'c'], dtype="string")
Out[2]:
0    a
1    b
2    c
dtype: string

In [3]: pd.Series(['a', 'b', 'c'], dtype=pd.StringDtype())
Out[3]:
0    a
1    b
2    c
dtype: string
```

Or `astype` after the Series or DataFrame is created

```
In [4]: s = pd.Series(['a', 'b', 'c'])

In [5]: s
Out[5]:
0    a
1    b
2    c
dtype: object

In [6]: s.astype("string")
Out[6]:
0    a
1    b
```

(continues on next page)

(continued from previous page)

```
2    c
dtype: string
```

Behavior differences

These are places where the behavior of `StringDtype` objects differ from `object` `dtype`

- I. For `StringDtype`, *string accessor methods* that return **numeric** output will always return a nullable integer `dtype`, rather than either int or float `dtype`, depending on the presence of NA values. Methods returning **boolean** output will return a nullable boolean `dtype`.

```
In [7]: s = pd.Series(["a", None, "b"], dtype="string")

In [8]: s
Out[8]:
0      a
1    <NA>
2      b
dtype: string

In [9]: s.str.count("a")
Out[9]:
0      1
1    <NA>
2      0
dtype: Int64

In [10]: s.dropna().str.count("a")
Out[10]:
0      1
2      0
dtype: Int64
```

Both outputs are `Int64` `dtype`. Compare that with `object-dtype`

```
In [11]: s2 = pd.Series(["a", None, "b"], dtype="object")

In [12]: s2.str.count("a")
Out[12]:
0    1.0
1    NaN
2    0.0
dtype: float64

In [13]: s2.dropna().str.count("a")
Out[13]:
0      1
2      0
dtype: int64
```

When NA values are present, the output `dtype` is `float64`. Similarly for methods returning boolean values.

```
In [14]: s.str.isdigit()
Out[14]:
0    False
```

(continues on next page)

(continued from previous page)

```

1      <NA>
2    False
dtype: boolean

In [15]: s.str.match("a")
Out[15]:
0    True
1    <NA>
2    False
dtype: boolean

```

2. Some string methods, like Series.str.decode() are not available on StringArray because StringArray only holds strings, not bytes.
3. In comparison operations, arrays.StringArray and Series backed by a StringArray will return an object with BooleanDtype, rather than a bool dtype object. Missing values in a StringArray will propagate in comparison operations, rather than always comparing unequal like numpy.nan.

Everything else that follows in the rest of this document applies equally to string and object dtype.

3.6.2 String Methods

Series and Index are equipped with a set of string processing methods that make it easy to operate on each element of the array. Perhaps most importantly, these methods exclude missing/NA values automatically. These are accessed via the str attribute and generally have names matching the equivalent (scalar) built-in string methods:

```

In [16]: s = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca', np.nan, 'CABA', 'dog', 'cat'],
....:                  dtype="string")
....:

In [17]: s.str.lower()
Out[17]:
0     a
1     b
2     c
3    aaba
4    baca
5    <NA>
6    caba
7    dog
8    cat
dtype: string

In [18]: s.str.upper()
Out[18]:
0     A
1     B
2     C
3    AABA
4    BACA
5    <NA>
6    CABA
7    DOG
8    CAT
dtype: string

```

(continues on next page)

(continued from previous page)

```
In [19]: s.str.len()
```

```
Out[19]:
```

```
0      1
1      1
2      1
3      4
4      4
5    <NA>
6      4
7      3
8      3
dtype: Int64
```

```
In [20]: idx = pd.Index([' jack', 'jill ', ' jesse ', 'frank'])
```

```
In [21]: idx.str.strip()
```

```
Out[21]: Index(['jack', 'jill', 'jesse', 'frank'], dtype='object')
```

```
In [22]: idx.str.lstrip()
```

```
Out[22]: Index(['jack', 'jill ', 'jesse ', 'frank'], dtype='object')
```

```
In [23]: idx.str.rstrip()
```

```
Out[23]: Index([' jack', 'jill', ' jesse', 'frank'], dtype='object')
```

The string methods on Index are especially useful for cleaning up or transforming DataFrame columns. For instance, you may have columns with leading or trailing whitespace:

```
In [24]: df = pd.DataFrame(np.random.randn(3, 2),
....:                     columns=[' Column A ', ' Column B '], index=range(3))
....:
```

```
In [25]: df
```

```
Out[25]:
```

	Column A	Column B
0	-0.061542	0.528296
1	-0.952849	2.392803
2	-1.524186	2.642204

Since df.columns is an Index object, we can use the .str accessor

```
In [26]: df.columns.str.strip()
```

```
Out[26]: Index(['Column A', 'Column B'], dtype='object')
```

```
In [27]: df.columns.str.lower()
```

```
Out[27]: Index([' column a ', ' column b '], dtype='object')
```

These string methods can then be used to clean up the columns as needed. Here we are removing leading and trailing whitespaces, lower casing all names, and replacing any remaining whitespaces with underscores:

```
In [28]: df.columns = df.columns.str.strip().str.lower().str.replace(' ', '_')
```

```
In [29]: df
```

```
Out[29]:
```

	column_a	column_b
0	-0.061542	0.528296
1	-0.952849	2.392803

(continues on next page)

(continued from previous page)

2 -1.524186 2.642204

Note: If you have a Series where lots of elements are repeated (i.e. the number of unique elements in the Series is a lot smaller than the length of the Series), it can be faster to convert the original Series to one of type category and then use .str.<method> or .dt.<property> on that. The performance difference comes from the fact that, for Series of type category, the string operations are done on the .categories and not on each element of the Series.

Please note that a Series of type category with string .categories has some limitations in comparison to Series of type string (e.g. you can't add strings to each other: s + " " + s won't work if s is a Series of type category). Also, .str methods which operate on elements of type list are not available on such a Series.

Warning: Before v.0.25.0, the .str-accessor did only the most rudimentary type checks. Starting with v.0.25.0, the type of the Series is inferred and the allowed types (i.e. strings) are enforced more rigorously.

Generally speaking, the .str accessor is intended to work only on strings. With very few exceptions, other uses are not supported, and may be disabled at a later point.

3.6.3 Splitting and replacing strings

Methods like split return a Series of lists:

```
In [30]: s2 = pd.Series(['a_b_c', 'c_d_e', np.nan, 'f_g_h'], dtype="string")
In [31]: s2.str.split('_')
Out[31]:
0    [a, b, c]
1    [c, d, e]
2    <NA>
3    [f, g, h]
dtype: object
```

Elements in the split lists can be accessed using get or [] notation:

```
In [32]: s2.str.split('_').str.get(1)
Out[32]:
0      b
1      d
2    <NA>
3      g
dtype: object

In [33]: s2.str.split('_').str[1]
Out[33]:
0      b
1      d
2    <NA>
3      g
dtype: object
```

It is easy to expand this to return a DataFrame using expand.

```
In [34]: s2.str.split('_', expand=True)
Out[34]:
      0      1      2
0    a    b    c
1    c    d    e
2  <NA>  <NA>  <NA>
3    f    g    h
```

When original Series has `StringDtype`, the output columns will all be `StringDtype` as well.

It is also possible to limit the number of splits:

```
In [35]: s2.str.split('_', expand=True, n=1)
Out[35]:
      0      1
0    a  b_c
1    c  d_e
2  <NA>  <NA>
3    f  g_h
```

`rsplit` is similar to `split` except it works in the reverse direction, i.e., from the end of the string to the beginning of the string:

```
In [36]: s2.str.rsplit('_', expand=True, n=1)
Out[36]:
      0      1
0  a_b    c
1  c_d    e
2  <NA>  <NA>
3  f_g    h
```

`replace` by default replaces regular expressions:

```
In [37]: s3 = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca',
.....:                   np.nan, 'CABA', 'dog', 'cat'],
.....:                   dtype="string")
.....:

In [38]: s3
Out[38]:
0      A
1      B
2      C
3    Aaba
4    Baca
5
6  <NA>
7    CABA
8    dog
9    cat
dtype: string

In [39]: s3.str.replace('^.a|dog', 'XX-XX ', case=False)
Out[39]:
0          A
1          B
2          C
3    XX-XX ba
```

(continues on next page)

(continued from previous page)

```

4    XX-XX ca
5
6        <NA>
7    XX-XX BA
8        XX-XX
9    XX-XX t
dtype: string

```

Some caution must be taken to keep regular expressions in mind! For example, the following code will cause trouble because of the regular expression meaning of `$`:

```

# Consider the following badly formatted financial data
In [40]: dollars = pd.Series(['12', '-$10', '$10,000'], dtype="string")

# This does what you'd naively expect:
In [41]: dollars.str.replace('$', '')
Out[41]:
0      12
1     -10
2  10,000
dtype: string

# But this doesn't:
In [42]: dollars.str.replace('-$', '-')
Out[42]:
0      12
1     -$10
2   $10,000
dtype: string

# We need to escape the special character (for >1 len patterns)
In [43]: dollars.str.replace(r'-\$', '-')
Out[43]:
0      12
1     -10
2   $10,000
dtype: string

```

New in version 0.23.0.

If you do want literal replacement of a string (equivalent to `str.replace()`), you can set the optional `regex` parameter to `False`, rather than escaping each character. In this case both `pat` and `repl` must be strings:

```

# These lines are equivalent
In [44]: dollars.str.replace(r'-\$', '-')
Out[44]:
0      12
1     -10
2   $10,000
dtype: string

In [45]: dollars.str.replace('-$', '-', regex=False)
Out[45]:
0      12
1     -10
2   $10,000
dtype: string

```

The `replace` method can also take a callable as replacement. It is called on every pat using `re.sub()`. The callable should expect one positional argument (a regex object) and return a string.

```
# Reverse every lowercase alphabetic word
In [46]: pat = r'[a-z]+'

In [47]: def repl(m):
....:     return m.group(0)[::-1]
....:

In [48]: pd.Series(['foo 123', 'bar baz', np.nan],
....:              dtype="string").str.replace(pat, repl)
....:

Out[48]:
0    oof 123
1    rab zab
2    <NA>
dtype: string

# Using regex groups
In [49]: pat = r"(?P<one>\w+) (?P<two>\w+) (?P<three>\w+)"
```

```
In [50]: def repl(m):
....:     return m.group('two').swapcase()
....:

In [51]: pd.Series(['Foo Bar Baz', np.nan],
....:              dtype="string").str.replace(pat, repl)
....:

Out[51]:
0    bAR
1    <NA>
dtype: string
```

The `replace` method also accepts a compiled regular expression object from `re.compile()` as a pattern. All flags should be included in the compiled regular expression object.

```
In [52]: import re

In [53]: regex_pat = re.compile(r'^.a|dog', flags=re.IGNORECASE)

In [54]: s3.str.replace(regex_pat, 'XX-XX ')
Out[54]:
0        A
1        B
2        C
3    XX-XX ba
4    XX-XX ca
5
6    <NA>
7    XX-XX BA
8    XX-XX
9    XX-XX t
dtype: string
```

Including a `flags` argument when calling `replace` with a compiled regular expression object will raise a `ValueError`.

```
In [55]: s3.str.replace(regex_pat, 'XX-XX ', flags=re.IGNORECASE)
```

```
ValueError: case and flags cannot be set when pat is a compiled regex
```

3.6.4 Concatenation

There are several ways to concatenate a Series or Index, either with itself or others, all based on `cat()`, resp. `Index.str.cat`.

Concatenating a single Series into a string

The content of a Series (or Index) can be concatenated:

```
In [56]: s = pd.Series(['a', 'b', 'c', 'd'], dtype="string")
```

```
In [57]: s.str.cat(sep=',')
```

```
Out[57]: 'a,b,c,d'
```

If not specified, the keyword `sep` for the separator defaults to the empty string, `sep=' '`:

```
In [58]: s.str.cat()
```

```
Out[58]: 'abcd'
```

By default, missing values are ignored. Using `na_rep`, they can be given a representation:

```
In [59]: t = pd.Series(['a', 'b', np.nan, 'd'], dtype="string")
```

```
In [60]: t.str.cat(sep=',')
```

```
Out[60]: 'a,b,d'
```

```
In [61]: t.str.cat(sep=',', na_rep='--')
```

```
Out[61]: 'a,b,--,d'
```

Concatenating a Series and something list-like into a Series

The first argument to `cat()` can be a list-like object, provided that it matches the length of the calling Series (or Index).

```
In [62]: s.str.cat(['A', 'B', 'C', 'D'])
```

```
Out[62]:
```

```
0      aA
```

```
1      bB
```

```
2      cC
```

```
3      dD
```

```
dtype: string
```

Missing values on either side will result in missing values in the result as well, *unless* `na_rep` is specified:

```
In [63]: s.str.cat(t)
```

```
Out[63]:
```

```
0      aa
```

```
1      bb
```

```
2      <NA>
```

(continues on next page)

(continued from previous page)

```
3      dd
dtype: string

In [64]: s.str.cat(t, na_rep='-' )
Out[64]:
0    aa
1    bb
2    c-
3    dd
dtype: string
```

Concatenating a Series and something array-like into a Series

New in version 0.23.0.

The parameter `others` can also be two-dimensional. In this case, the number or rows must match the lengths of the calling Series (or Index).

```
In [65]: d = pd.concat([t, s], axis=1)

In [66]: s
Out[66]:
0    a
1    b
2    c
3    d
dtype: string

In [67]: d
Out[67]:
   0  1
0    a  a
1    b  b
2  <NA>  c
3    d  d

In [68]: s.str.cat(d, na_rep='-' )
Out[68]:
0    aaa
1    bbb
2    c-c
3    ddd
dtype: string
```

Concatenating a Series and an indexed object into a Series, with alignment

New in version 0.23.0.

For concatenation with a Series or DataFrame, it is possible to align the indexes before concatenation by setting the `join`-keyword.

```
In [69]: u = pd.Series(['b', 'd', 'a', 'c'], index=[1, 3, 0, 2],
....:                  dtype="string")
....:
```

(continues on next page)

(continued from previous page)

```
In [70]: s
Out[70]:
0    a
1    b
2    c
3    d
dtype: string

In [71]: u
Out[71]:
1    b
3    d
0    a
2    c
dtype: string

In [72]: s.str.cat(u)
Out[72]:
0    aa
1    bb
2    cc
3    dd
dtype: string

In [73]: s.str.cat(u, join='left')
Out[73]:
0    aa
1    bb
2    cc
3    dd
dtype: string
```

Warning: If the `join` keyword is not passed, the method `cat()` will currently fall back to the behavior before version 0.23.0 (i.e. no alignment), but a `FutureWarning` will be raised if any of the involved indexes differ, since this default will change to `join='left'` in a future version.

The usual options are available for `join` (one of `'left'`, `'outer'`, `'inner'`, `'right'`). In particular, alignment also means that the different lengths do not need to coincide anymore.

```
In [74]: v = pd.Series(['z', 'a', 'b', 'd', 'e'], index=[-1, 0, 1, 3, 4],
....:                  dtype="string")
....:

In [75]: s
Out[75]:
0    a
1    b
2    c
3    d
dtype: string

In [76]: v
Out[76]:
```

(continues on next page)

(continued from previous page)

```
-1      z
 0      a
 1      b
 3      d
 4      e
dtype: string

In [77]: s.str.cat(v, join='left', na_rep=' ')
Out[77]:
0    aa
1    bb
2    c-
3    dd
dtype: string

In [78]: s.str.cat(v, join='outer', na_rep=' ')
Out[78]:
-1     -z
 0     aa
 1     bb
 2     c-
 3     dd
 4     -e
dtype: string
```

The same alignment can be used when `others` is a DataFrame:

```
In [79]: f = d.loc[[3, 2, 1, 0], :]
In [80]: s
Out[80]:
0    a
1    b
2    c
3    d
dtype: string

In [81]: f
Out[81]:
   0  1
3  d  d
2 <NA>  c
1    b  b
0    a  a

In [82]: s.str.cat(f, join='left', na_rep=' ')
Out[82]:
0    aaa
1    bbb
2    c-c
3    ddd
dtype: string
```

Concatenating a Series and many objects into a Series

Several array-like items (specifically: Series, Index, and 1-dimensional variants of np.ndarray) can be combined in a list-like container (including iterators, dict-views, etc.).

```
In [83]: s
Out[83]:
0    a
1    b
2    c
3    d
dtype: string

In [84]: u
Out[84]:
1    b
3    d
0    a
2    c
dtype: string

In [85]: s.str.cat([u, u.to_numpy()], join='left')
Out[85]:
0    aab
1    bbd
2    cca
3    ddc
dtype: string
```

All elements without an index (e.g. np.ndarray) within the passed list-like must match in length to the calling Series (or Index), but Series and Index may have arbitrary length (as long as alignment is not disabled with join=None):

```
In [86]: v
Out[86]:
-1    z
 0    a
 1    b
 3    d
 4    e
dtype: string

In [87]: s.str.cat([v, u, u.to_numpy()], join='outer', na_rep='--')
Out[87]:
-1    --z--
 0    aaab
 1    bbbd
 2    c-ca
 3    ddc
 4    --e--
dtype: string
```

If using join='right' on a list-like of others that contains different indexes, the union of these indexes will be used as the basis for the final concatenation:

```
In [88]: u.loc[[3]]
Out[88]:
```

(continues on next page)

(continued from previous page)

```
3      d
dtype: string

In [89]: v.loc[[-1, 0]]
Out[89]:
-1      z
 0      a
dtype: string

In [90]: s.str.cat([u.loc[[3]], v.loc[[-1, 0]]], join='right', na_rep='--')
Out[90]:
-1    --z
 0    a-a
 3    dd-
dtype: string
```

3.6.5 Indexing with .str

You can use [] notation to directly index by position locations. If you index past the end of the string, the result will be a NaN.

```
In [91]: s = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca', np.nan,
.....:           'CABA', 'dog', 'cat'],
.....:           dtype="string")
.....:

In [92]: s.str[0]
Out[92]:
0      A
1      B
2      C
3      A
4      B
5      <NA>
6      C
7      d
8      c
dtype: string

In [93]: s.str[1]
Out[93]:
0      <NA>
1      <NA>
2      <NA>
3      a
4      a
5      <NA>
6      A
7      o
8      a
dtype: string
```

3.6.6 Extracting substrings

Extract first match in each subject (extract)

Warning: Before version 0.23, argument `expand` of the `extract` method defaulted to `False`. When `expand=False`, `expand` returns a Series, Index, or DataFrame, depending on the subject and regular expression pattern. When `expand=True`, it always returns a DataFrame, which is more consistent and less confusing from the perspective of a user. `expand=True` has been the default since version 0.23.0.

The `extract` method accepts a regular expression with at least one capture group.

Extracting a regular expression with more than one group returns a DataFrame with one column per group.

```
In [94]: pd.Series(['a1', 'b2', 'c3'],
....:                 dtype="string").str.extract(r'([ab]) (\d)', expand=False)
....:
Out[94]:
   0    1
0  a  1
1  b  2
2 <NA> <NA>
```

Elements that do not match return a row filled with NaN. Thus, a Series of messy strings can be “converted” into a like-indexed Series or DataFrame of cleaned-up or more useful strings, without necessitating `get()` to access tuples or `re.match` objects. The `dtype` of the result is always object, even if no match is found and the result only contains NaN.

Named groups like

```
In [95]: pd.Series(['a1', 'b2', 'c3'],
....:                 dtype="string").str.extract(r'(?P<letter>[ab]) (?P<digit>\d)',
....:                                         expand=False)
....:
Out[95]:
  letter digit
0      a     1
1      b     2
2    <NA>  <NA>
```

and optional groups like

```
In [96]: pd.Series(['a1', 'b2', '3'],
....:                 dtype="string").str.extract(r'([ab])?(\d)', expand=False)
....:
Out[96]:
   0  1
0  a  1
1  b  2
2 <NA> 3
```

can also be used. Note that any capture group names in the regular expression will be used for column names; otherwise capture group numbers will be used.

Extracting a regular expression with one group returns a DataFrame with one column if `expand=True`.

```
In [97]: pd.Series(['a1', 'b2', 'c3'],
....:                 dtype="string").str.extract(r'[ab](\d)', expand=True)
....:
Out[97]:
0
1
2
2 <NA>
```

It returns a Series if expand=False.

```
In [98]: pd.Series(['a1', 'b2', 'c3'],
....:                 dtype="string").str.extract(r'[ab](\d)', expand=False)
....:
Out[98]:
0      1
1      2
2    <NA>
dtype: string
```

Calling on an Index with a regex with exactly one capture group returns a DataFrame with one column if expand=True.

```
In [99]: s = pd.Series(["a1", "b2", "c3"], ["A11", "B22", "C33"],
....:                     dtype="string")
....:

In [100]: s
Out[100]:
A11    a1
B22    b2
C33    c3
dtype: string

In [101]: s.index.str.extract("(?P<letter>[a-zA-Z])", expand=True)
Out[101]:
  letter
0      A
1      B
2      C
```

It returns an Index if expand=False.

```
In [102]: s.index.str.extract("(?P<letter>[a-zA-Z])", expand=False)
Out[102]: Index(['A', 'B', 'C'], dtype='object', name='letter')
```

Calling on an Index with a regex with more than one capture group returns a DataFrame if expand=True.

```
In [103]: s.index.str.extract("(?P<letter>[a-zA-Z])([0-9]+)", expand=True)
Out[103]:
  letter  1
0      A  11
1      B  22
2      C  33
```

It raises ValueError if expand=False.

```
>>> s.index.str.extract("(?P<letter>[a-zA-Z]) ([0-9]+)", expand=False)
ValueError: only one regex group is supported with Index
```

The table below summarizes the behavior of `extract` (`expand=False`) (input subject in first column, number of groups in regex in first row)

	1 group	>1 group
Index	Index	ValueError
Series	Series	DataFrame

Extract all matches in each subject (extractall)

Unlike `extract` (which returns only the first match),

```
In [104]: s = pd.Series(["a1a2", "b1", "c1"], index=["A", "B", "C"],
.....:                 dtype="string")
.....:

In [105]: s
Out[105]:
A    a1a2
B    b1
C    c1
dtype: string

In [106]: two_groups = '(?P<letter>[a-z]) (?P<digit>[0-9])'

In [107]: s.str.extract(two_groups, expand=True)
Out[107]:
   letter  digit
A      a      1
B      b      1
C      c      1
```

the `extractall` method returns every match. The result of `extractall` is always a DataFrame with a MultiIndex on its rows. The last level of the MultiIndex is named `match` and indicates the order in the subject.

```
In [108]: s.str.extractall(two_groups)
Out[108]:
   letter  digit
   match
A  0        a      1
   1        a      2
B  0        b      1
C  0        c      1
```

When each subject string in the Series has exactly one match,

```
In [109]: s = pd.Series(['a3', 'b3', 'c2'], dtype="string")

In [110]: s
Out[110]:
0    a3
1    b3
```

(continues on next page)

(continued from previous page)

```
2    c2
dtype: string
```

then `extractall(pat).xs(0, level='match')` gives the same result as `extract(pat)`.

```
In [111]: extract_result = s.str.extract(two_groups, expand=True)
```

```
In [112]: extract_result
```

```
Out[112]:
```

```
letter digit
0      a      3
1      b      3
2      c      2
```

```
In [113]: extractall_result = s.str.extractall(two_groups)
```

```
In [114]: extractall_result
```

```
Out[114]:
```

```
letter digit
match
0 0        a      3
1 0        b      3
2 0        c      2
```

```
In [115]: extractall_result.xs(0, level="match")
```

```
Out[115]:
```

```
letter digit
0      a      3
1      b      3
2      c      2
```

Index also supports `.str.extractall`. It returns a DataFrame which has the same result as a Series.`str.extractall` with a default index (starts from 0).

```
In [116]: pd.Index(["ala2", "b1", "c1"]).str.extractall(two_groups)
```

```
Out[116]:
```

```
letter digit
match
0 0        a      1
1        a      2
1 0        b      1
2 0        c      1
```

```
In [117]: pd.Series(["ala2", "b1", "c1"], dtype="string").str.extractall(two_groups)
```

```
Out[117]:
```

```
letter digit
match
0 0        a      1
1        a      2
1 0        b      1
2 0        c      1
```

3.6.7 Testing for Strings that match or contain a pattern

You can check whether elements contain a pattern:

```
In [118]: pattern = r'[0-9][a-z]'

In [119]: pd.Series(['1', '2', '3a', '3b', '03c'],
.....:           dtype="string").str.contains(pattern)
.....:

Out[119]:
0    False
1    False
2     True
3     True
4     True
dtype: boolean
```

Or whether elements match a pattern:

```
In [120]: pd.Series(['1', '2', '3a', '3b', '03c'],
.....:           dtype="string").str.match(pattern)
.....:

Out[120]:
0    False
1    False
2     True
3     True
4    False
dtype: boolean
```

The distinction between `match` and `contains` is strictness: `match` relies on strict `re.match`, while `contains` relies on `re.search`.

Methods like `match`, `contains`, `startswith`, and `endswith` take an extra `na` argument so missing values can be considered True or False:

```
In [121]: s4 = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca', np.nan, 'CABA', 'dog', 'cat',
.....:           dtype="string")
.....:

In [122]: s4.str.contains('A', na=False)
Out[122]:
0     True
1    False
2    False
3     True
4    False
5    False
6     True
7    False
8    False
dtype: boolean
```

3.6.8 Creating indicator variables

You can extract dummy variables from string columns. For example if they are separated by a '|':

```
In [123]: s = pd.Series(['a', 'a|b', np.nan, 'a|c'], dtype="string")  
  
In [124]: s.str.get_dummies(sep='|')  
Out[124]:  
   a   b   c  
0  1  0  0  
1  1  1  0  
2  0  0  0  
3  1  0  1
```

String Index also supports `get_dummies` which returns a MultiIndex.

```
In [125]: idx = pd.Index(['a', 'a|b', np.nan, 'a|c'])  
  
In [126]: idx.str.get_dummies(sep='|')  
Out[126]:  
MultiIndex([(1, 0, 0),  
            (1, 1, 0),  
            (0, 0, 0),  
            (1, 0, 1)],  
           names=['a', 'b', 'c'])
```

See also [get_dummies\(\)](#).

3.6.9 Method summary

Method	Description
<code>cat()</code>	Concatenate strings
<code>split()</code>	Split strings on delimiter
<code>rsplit()</code>	Split strings on delimiter working from the end of the string
<code>get()</code>	Index into each element (retrieve i-th element)
<code>join()</code>	Join strings in each element of the Series with passed separator
<code>get_dummies()</code>	Split strings on the delimiter returning DataFrame of dummy variables
<code>contains()</code>	Return boolean array if each string contains pattern/regex
<code>replace()</code>	Replace occurrences of pattern/regex/string with some other string or the return value of a callable given the occurrence
<code>repeat()</code>	Duplicate values (<code>s.str.repeat(3)</code> equivalent to <code>x * 3</code>)
<code>pad()</code>	Add whitespace to left, right, or both sides of strings
<code>center()</code>	Equivalent to <code>str.center</code>
<code>ljust()</code>	Equivalent to <code>str.ljust</code>
<code>rjust()</code>	Equivalent to <code>str.rjust</code>
<code>zfill()</code>	Equivalent to <code>str.zfill</code>
<code>wrap()</code>	Split long strings into lines with length less than a given width
<code>slice()</code>	Slice each string in the Series
<code>slice_replace()</code>	Replace slice in each string with passed value
<code>count()</code>	Count occurrences of pattern
<code>startswith()</code>	Equivalent to <code>str.startswith(pat)</code> for each element
<code>endswith()</code>	Equivalent to <code>str.endswith(pat)</code> for each element

Continued on next page

Table 2 – continued from previous page

Method	Description
findall()	Compute list of all occurrences of pattern/regex for each string
match()	Call <code>re.match</code> on each element, returning matched groups as list
extract()	Call <code>re.search</code> on each element, returning DataFrame with one row for each element and one column for each regex capture group
extractall()	Call <code>re.findall</code> on each element, returning DataFrame with one row for each match and one column for each regex capture group
len()	Compute string lengths
strip()	Equivalent to <code>str.strip</code>
rstrip()	Equivalent to <code>str.rstrip</code>
lstrip()	Equivalent to <code>str.lstrip</code>
partition()	Equivalent to <code>str.partition</code>
rpartition()	Equivalent to <code>str.rpartition</code>
lower()	Equivalent to <code>str.lower</code>
casefold()	Equivalent to <code>str.casefold</code>
upper()	Equivalent to <code>str.upper</code>
find()	Equivalent to <code>str.find</code>
rfind()	Equivalent to <code>str.rfind</code>
index()	Equivalent to <code>str.index</code>
rindex()	Equivalent to <code>str.rindex</code>
capitalize()	Equivalent to <code>str.capitalize</code>
swapcase()	Equivalent to <code>str.swapcase</code>
normalize()	Return Unicode normal form. Equivalent to <code>unicodedata.normalize</code>
translate()	Equivalent to <code>str.translate</code>
isalnum()	Equivalent to <code>str.isalnum</code>
isalpha()	Equivalent to <code>str.isalpha</code>
isdigit()	Equivalent to <code>str.isdigit</code>
isspace()	Equivalent to <code>str.isspace</code>
islower()	Equivalent to <code>str.islower</code>
isupper()	Equivalent to <code>str.isupper</code>
istitle()	Equivalent to <code>str.istitle</code>
isnumeric()	Equivalent to <code>str.isnumeric</code>
isdecimal()	Equivalent to <code>str.isdecimal</code>

{{ header }}

3.7 Working with missing data

In this section, we will discuss missing (also referred to as NA) values in pandas.

Note: The choice of using NaN internally to denote missing data was largely for simplicity and performance reasons. Starting from pandas 1.0, some optional data types start experimenting with a native NA scalar using a mask-based approach. See [here](#) for more.

See the [cookbook](#) for some advanced strategies.

3.7.1 Values considered “missing”

As data comes in many shapes and forms, pandas aims to be flexible with regard to handling missing data. While `NaN` is the default missing value marker for reasons of computational speed and convenience, we need to be able to easily detect this value with data of different types: floating point, integer, boolean, and general object. In many cases, however, the Python `None` will arise and we wish to also consider that “missing” or “not available” or “NA”.

Note: If you want to consider `inf` and `-inf` to be “NA” in computations, you can set `pandas.options.mode.use_inf_as_na = True`.

```
In [1]: df = pd.DataFrame(np.random.randn(5, 3), index=['a', 'c', 'e', 'f', 'h'],
...:                         columns=['one', 'two', 'three'])
...:

In [2]: df['four'] = 'bar'

In [3]: df['five'] = df['one'] > 0

In [4]: df
Out[4]:
   one      two      three four five
a  1.470357  0.517558  1.495133 bar  True
c -2.009772  1.271870 -0.020355 bar False
e -0.737611  0.272524  2.048328 bar False
f -0.896220  0.350183  1.042304 bar False
h -1.887824  1.094870  1.029304 bar False

In [5]: df2 = df.reindex(['a', 'b', 'c', 'd', 'e', 'f', 'g', 'h'])

In [6]: df2
Out[6]:
   one      two      three four five
a  1.470357  0.517558  1.495133 bar  True
b    NaN        NaN        NaN    NaN
c -2.009772  1.271870 -0.020355 bar False
d    NaN        NaN        NaN    NaN
e -0.737611  0.272524  2.048328 bar False
f -0.896220  0.350183  1.042304 bar False
g    NaN        NaN        NaN    NaN
h -1.887824  1.094870  1.029304 bar False
```

To make detecting missing values easier (and across different array dtypes), pandas provides the `isna()` and `notna()` functions, which are also methods on Series and DataFrame objects:

```
In [7]: df2['one']
Out[7]:
a    1.470357
b    NaN
c   -2.009772
d    NaN
e   -0.737611
f   -0.896220
g    NaN
h   -1.887824
Name: one, dtype: float64
```

(continues on next page)

(continued from previous page)

In [8]: pd.isna(df2['one'])**Out[8]:**

```
a    False
b     True
c    False
d     True
e    False
f    False
g     True
h    False
Name: one, dtype: bool
```

In [9]: df2['four'].notna()**Out[9]:**

```
a     True
b    False
c     True
d    False
e     True
f     True
g    False
h     True
Name: four, dtype: bool
```

In [10]: df2.isna()**Out[10]:**

	one	two	three	four	five
a	False	False	False	False	False
b	True	True	True	True	True
c	False	False	False	False	False
d	True	True	True	True	True
e	False	False	False	False	False
f	False	False	False	False	False
g	True	True	True	True	True
h	False	False	False	False	False

Warning: One has to be mindful that in Python (and NumPy), the nan's don't compare equal, but None's do.
Note that pandas/NumPy uses the fact that np.nan != np.nan, and treats None like np.nan.

In [11]: None == None

noqa: E711

Out[11]: True**In [12]:** np.nan == np.nan**Out[12]:** False

So as compared to above, a scalar equality comparison versus a None/np.nan doesn't provide useful information.

In [13]: df2['one'] == np.nan**Out[13]:**

```
a    False
b    False
c    False
d    False
e    False
f    False
g    False
h   False
Name: one, dtype: bool
```

Integer dtypes and missing data

Because NaN is a float, a column of integers with even one missing values is cast to floating-point dtype (see [Support for integer NA](#) for more). Pandas provides a nullable integer array, which can be used by explicitly requesting the dtype:

```
In [14]: pd.Series([1, 2, np.nan, 4], dtype=pd.Int64Dtype())
Out[14]:
0      1
1      2
2    <NA>
3      4
dtype: Int64
```

Alternatively, the string alias `dtype='Int64'` (note the capital "I") can be used.

See [Nullable integer data type](#) for more.

Datetimes

For datetime64[ns] types, NaT represents missing values. This is a pseudo-native sentinel value that can be represented by NumPy in a singular dtype (datetime64[ns]). pandas objects provide compatibility between NaT and NaN.

```
In [15]: df2 = df.copy()

In [16]: df2['timestamp'] = pd.Timestamp('20120101')

In [17]: df2
Out[17]:
   one      two      three  four   five  timestamp
a  1.470357  0.517558  1.495133  bar  True  2012-01-01
c -2.009772  1.271870 -0.020355  bar  False 2012-01-01
e -0.737611  0.272524  2.048328  bar  False 2012-01-01
f -0.896220  0.350183  1.042304  bar  False 2012-01-01
h -1.887824  1.094870  1.029304  bar  False 2012-01-01

In [18]: df2.loc[['a', 'c', 'h'], ['one', 'timestamp']] = np.nan

In [19]: df2
Out[19]:
   one      two      three  four   five  timestamp
a     NaN  0.517558  1.495133  bar  True      NaT
c     NaN  1.271870 -0.020355  bar  False     NaT
e -0.737611  0.272524  2.048328  bar  False 2012-01-01
f -0.896220  0.350183  1.042304  bar  False 2012-01-01
h     NaN  1.094870  1.029304  bar  False     NaT

In [20]: df2.dtypes.value_counts()
Out[20]:
float64      3
datetime64[ns]  1
bool          1
object         1
dtype: int64
```

3.7.2 Inserting missing data

You can insert missing values by simply assigning to containers. The actual missing value used will be chosen based on the dtype.

For example, numeric containers will always use NaN regardless of the missing value type chosen:

```
In [21]: s = pd.Series([1, 2, 3])
In [22]: s.loc[0] = None
In [23]: s
Out[23]:
0      NaN
1      2.0
2      3.0
dtype: float64
```

Likewise, datetime containers will always use NaT.

For object containers, pandas will use the value given:

```
In [24]: s = pd.Series(["a", "b", "c"])
In [25]: s.loc[0] = None
In [26]: s.loc[1] = np.nan
In [27]: s
Out[27]:
0      None
1      NaN
2      c
dtype: object
```

3.7.3 Calculations with missing data

Missing values propagate naturally through arithmetic operations between pandas objects.

```
In [28]: a
Out[28]:
      one      two
a    NaN  0.517558
c    NaN  1.271870
e -0.737611  0.272524
f -0.896220  0.350183
h -0.896220  1.094870

In [29]: b
Out[29]:
      one      two      three
a    NaN  0.517558  1.495133
c    NaN  1.271870 -0.020355
e -0.737611  0.272524  2.048328
f -0.896220  0.350183  1.042304
h    NaN  1.094870  1.029304
```

(continues on next page)

(continued from previous page)

```
In [30]: a + b
Out[30]:
      one   three      two
a     NaN     NaN  1.035115
c     NaN     NaN  2.543739
e -1.475222    NaN  0.545049
f -1.792440    NaN  0.700366
h     NaN     NaN  2.189741
```

The descriptive statistics and computational methods discussed in the [data structure overview](#) (and listed [here](#) and [here](#)) are all written to account for missing data. For example:

- When summing data, NA (missing) values will be treated as zero.
- If the data are all NA, the result will be 0.
- Cumulative methods like `cumsum()` and `cumprod()` ignore NA values by default, but preserve them in the resulting arrays. To override this behaviour and include NA values, use `skipna=False`.

```
In [31]: df
Out[31]:
      one      two      three
a     NaN  0.517558  1.495133
c     NaN  1.271870 -0.020355
e -0.737611  0.272524  2.048328
f -0.896220  0.350183  1.042304
h     NaN  1.094870  1.029304
```

```
In [32]: df['one'].sum()
Out[32]: -1.6338307670509524
```

```
In [33]: df.mean(1)
```

```
Out[33]:
a    1.006345
c    0.625757
e    0.527747
f    0.165422
h    1.062087
dtype: float64
```

```
In [34]: df.cumsum()
```

```
Out[34]:
      one      two      three
a     NaN  0.517558  1.495133
c     NaN  1.789427  1.474778
e -0.737611  2.061952  3.523106
f -1.633831  2.412135  4.565410
h     NaN  3.507005  5.594714
```

```
In [35]: df.cumsum(skipna=False)
```

```
Out[35]:
      one      two      three
a   NaN  0.517558  1.495133
c   NaN  1.789427  1.474778
e   NaN  2.061952  3.523106
f   NaN  2.412135  4.565410
h   NaN  3.507005  5.594714
```

3.7.4 Sum/prod of empties/nans

Warning: This behavior is now standard as of v0.22.0 and is consistent with the default in numpy; previously sum/prod of all-NA or empty Series/DataFrames would return NaN. See [v0.22.0 whatsnew](#) for more.

The sum of an empty or all-NA Series or column of a DataFrame is 0.

```
In [36]: pd.Series([np.nan]).sum()
Out[36]: 0.0
```

```
In [37]: pd.Series([], dtype="float64").sum()
Out[37]: 0.0
```

The product of an empty or all-NA Series or column of a DataFrame is 1.

```
In [38]: pd.Series([np.nan]).prod()
Out[38]: 1.0
```

```
In [39]: pd.Series([], dtype="float64").prod()
Out[39]: 1.0
```

3.7.5 NA values in GroupBy

NA groups in GroupBy are automatically excluded. This behavior is consistent with R, for example:

```
In [40]: df
Out[40]:
   one      two      three
a    NaN  0.517558  1.495133
c    NaN  1.271870 -0.020355
e -0.737611  0.272524  2.048328
f -0.896220  0.350183  1.042304
h    NaN  1.094870  1.029304
```

```
In [41]: df.groupby('one').mean()
Out[41]:
      two      three
one
-0.896220  0.350183  1.042304
-0.737611  0.272524  2.048328
```

See the groupby section [here](#) for more information.

Cleaning / filling missing data

pandas objects are equipped with various data manipulation methods for dealing with missing data.

3.7.6 Filling missing values: `fillna`

`fillna()` can “fill in” NA values with non-NA data in a couple of ways, which we illustrate:

Replace NA with a scalar value

```
In [42]: df2
Out[42]:
      one      two      three  four   five timestamp
a    NaN  0.517558  1.495133  bar  True      NaT
c    NaN  1.271870 -0.020355  bar False      NaT
e -0.737611  0.272524  2.048328  bar False 2012-01-01
f -0.896220  0.350183  1.042304  bar False 2012-01-01
h    NaN  1.094870  1.029304  bar False      NaT

In [43]: df2.fillna(0)
Out[43]:
      one      two      three  four   five timestamp
a  0.000000  0.517558  1.495133  bar  True          0
c  0.000000  1.271870 -0.020355  bar False          0
e -0.737611  0.272524  2.048328  bar False 2012-01-01 00:00:00
f -0.896220  0.350183  1.042304  bar False 2012-01-01 00:00:00
h  0.000000  1.094870  1.029304  bar False          0

In [44]: df2['one'].fillna('missing')
Out[44]:
a      missing
c      missing
e    -0.737611
f    -0.896220
h      missing
Name: one, dtype: object
```

Fill gaps forward or backward

Using the same filling arguments as `reindexing`, we can propagate non-NA values forward or backward:

```
In [45]: df
Out[45]:
      one      two      three
a    NaN  0.517558  1.495133
c    NaN  1.271870 -0.020355
e -0.737611  0.272524  2.048328
f -0.896220  0.350183  1.042304
h    NaN  1.094870  1.029304

In [46]: df.fillna(method='pad')
Out[46]:
      one      two      three
a    NaN  0.517558  1.495133
c    NaN  1.271870 -0.020355
e -0.737611  0.272524  2.048328
f -0.896220  0.350183  1.042304
h -0.896220  1.094870  1.029304
```

Limit the amount of filling

If we only want consecutive gaps filled up to a certain number of data points, we can use the `limit` keyword:

```
In [47]: df
Out[47]:
   one      two      three
a  NaN  0.517558  1.495133
c  NaN  1.271870 -0.020355
e  NaN      NaN      NaN
f  NaN      NaN      NaN
h  NaN  1.094870  1.029304

In [48]: df.fillna(method='pad', limit=1)
Out[48]:
   one      two      three
a  NaN  0.517558  1.495133
c  NaN  1.271870 -0.020355
e  NaN  1.271870 -0.020355
f  NaN      NaN      NaN
h  NaN  1.094870  1.029304
```

To remind you, these are the available filling methods:

Method	Action
pad / ffill	Fill values forward
bfill / backfill	Fill values backward

With time series data, using pad/ffill is extremely common so that the “last known value” is available at every time point.

`ffill()` is equivalent to `fillna(method='ffill')` and `bfill()` is equivalent to `fillna(method='bfill')`

3.7.7 Filling with a PandasObject

You can also fillna using a dict or Series that is alignable. The labels of the dict or index of the Series must match the columns of the frame you wish to fill. The use case of this is to fill a DataFrame with the mean of that column.

```
In [49]: dff = pd.DataFrame(np.random.randn(10, 3), columns=list('ABC'))
In [50]: dff.iloc[3:5, 0] = np.nan
In [51]: dff.iloc[4:6, 1] = np.nan
In [52]: dff.iloc[5:8, 2] = np.nan
In [53]: dff
Out[53]:
       A      B      C
0 -0.841820  0.746136 -0.245717
1 -1.156726  0.446539  0.224149
2 -1.231386 -0.302564  0.819234
3      NaN  0.115153 -1.780373
4      NaN      NaN  0.234816
5  0.343207      NaN      NaN
```

(continues on next page)

(continued from previous page)

```
6  0.984642 -0.812285      NaN
7  0.355619 -0.091436      NaN
8 -0.771807  0.132621  0.787468
9  0.336740 -0.817529 -1.712467
```

In [54]: `dff.fillna(dff.mean())`

Out [54]:

	A	B	C
0	-0.841820	0.746136	-0.245717
1	-1.156726	0.446539	0.224149
2	-1.231386	-0.302564	0.819234
3	-0.247691	0.115153	-1.780373
4	-0.247691	-0.072921	0.234816
5	0.343207	-0.072921	-0.238984
6	0.984642	-0.812285	-0.238984
7	0.355619	-0.091436	-0.238984
8	-0.771807	0.132621	0.787468
9	0.336740	-0.817529	-1.712467

In [55]: `dff.fillna(dff.mean() ['B' : 'C'])`

Out [55]:

	A	B	C
0	-0.841820	0.746136	-0.245717
1	-1.156726	0.446539	0.224149
2	-1.231386	-0.302564	0.819234
3	NaN	0.115153	-1.780373
4	NaN	-0.072921	0.234816
5	0.343207	-0.072921	-0.238984
6	0.984642	-0.812285	-0.238984
7	0.355619	-0.091436	-0.238984
8	-0.771807	0.132621	0.787468
9	0.336740	-0.817529	-1.712467

Same result as above, but is aligning the ‘fill’ value which is a Series in this case.

In [56]: `dff.where(pd.notna(dff), dff.mean(), axis='columns')`

Out [56]:

	A	B	C
0	-0.841820	0.746136	-0.245717
1	-1.156726	0.446539	0.224149
2	-1.231386	-0.302564	0.819234
3	-0.247691	0.115153	-1.780373
4	-0.247691	-0.072921	0.234816
5	0.343207	-0.072921	-0.238984
6	0.984642	-0.812285	-0.238984
7	0.355619	-0.091436	-0.238984
8	-0.771807	0.132621	0.787468
9	0.336740	-0.817529	-1.712467

3.7.8 Dropping axis labels with missing data: dropna

You may wish to simply exclude labels from a data set which refer to missing data. To do this, use `dropna()`:

```
In [57]: df
Out[57]:
   one      two      three
a  NaN  0.517558  1.495133
c  NaN  1.271870 -0.020355
e  NaN  0.000000  0.000000
f  NaN  0.000000  0.000000
h  NaN  1.094870  1.029304

In [58]: df.dropna(axis=0)
Out[58]:
Empty DataFrame
Columns: [one, two, three]
Index: []

In [59]: df.dropna(axis=1)
Out[59]:
      two      three
a  0.517558  1.495133
c  1.271870 -0.020355
e  0.000000  0.000000
f  0.000000  0.000000
h  1.094870  1.029304

In [60]: df['one'].dropna()
Out[60]: Series([], Name: one, dtype: float64)
```

An equivalent `dropna()` is available for Series. `DataFrame.dropna` has considerably more options than `Series.dropna`, which can be examined [in the API](#).

3.7.9 Interpolation

New in version 0.23.0: The `limit_area` keyword argument was added.

Both Series and DataFrame objects have `interpolate()` that, by default, performs linear interpolation at missing data points.

```
In [61]: ts
Out[61]:
2000-01-31    0.469112
2000-02-29      NaN
2000-03-31      NaN
2000-04-28      NaN
2000-05-31      NaN
...
2007-12-31   -6.950267
2008-01-31   -7.904475

2008-02-29   -6.441779
2008-03-31   -8.184940
2008-04-30   -9.011531
Freq: BM, Length: 100, dtype: float64
```

```
In [65]: ts.interpolate().count()
```

```
Out[65]: 100
```

```
In [66]: ts.interpolate().plot()
```

(continues on next page)

(continued from previous page)

Out [66]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d64542510>

Index aware interpolation is available via the `method` keyword:

In [67]: ts2**Out [67]:**

```
2000-01-31    0.469112
2000-02-29      NaN
2002-07-31   -5.785037
2005-01-31      NaN
2008-04-30   -9.011531
dtype: float64
```

In [68]: ts2.interpolate()**Out [68]:**

```
2000-01-31    0.469112
2000-02-29   -2.657962
2002-07-31   -5.785037
2005-01-31   -7.398284
2008-04-30   -9.011531
dtype: float64
```

In [69]: ts2.interpolate(method='time')**Out [69]:**

(continues on next page)

(continued from previous page)

```
2000-01-31    0.469112
2000-02-29    0.270241
2002-07-31   -5.785037
2005-01-31   -7.190866
2008-04-30   -9.011531
dtype: float64
```

For a floating-point index, use `method='values'`:

```
In [70]: ser
Out[70]:
0.0      0.0
1.0      NaN
10.0     10.0
dtype: float64

In [71]: ser.interpolate()
Out[71]:
0.0      0.0
1.0      5.0
10.0     10.0
dtype: float64

In [72]: ser.interpolate(method='values')
Out[72]:
0.0      0.0
1.0      1.0
10.0     10.0
dtype: float64
```

You can also interpolate with a DataFrame:

```
In [73]: df = pd.DataFrame({'A': [1, 2.1, np.nan, 4.7, 5.6, 6.8],
....:                      'B': [.25, np.nan, np.nan, 4, 12.2, 14.4]})

In [74]: df
Out[74]:
       A      B
0  1.0  0.25
1  2.1  NaN
2  NaN  NaN
3  4.7  4.00
4  5.6  12.20
5  6.8  14.40

In [75]: df.interpolate()
Out[75]:
       A      B
0  1.0  0.25
1  2.1  1.50
2  3.4  2.75
3  4.7  4.00
4  5.6  12.20
5  6.8  14.40
```

The `method` argument gives access to fancier interpolation methods. If you have `scipy` installed, you can pass the

name of a 1-d interpolation routine to `method`. You'll want to consult the full [scipy interpolation documentation](#) and reference [guide](#) for details. The appropriate interpolation method will depend on the type of data you are working with.

- If you are dealing with a time series that is growing at an increasing rate, `method='quadratic'` may be appropriate.
- If you have values approximating a cumulative distribution function, then `method='pchip'` should work well.
- To fill missing values with goal of smooth plotting, consider `method='akima'`.

Warning: These methods require `scipy`.

```
In [76]: df.interpolate(method='barycentric')
```

```
Out[76]:
```

	A	B
0	1.00	0.250
1	2.10	-7.660
2	3.53	-4.515
3	4.70	4.000
4	5.60	12.200
5	6.80	14.400

```
In [77]: df.interpolate(method='pchip')
```

```
Out[77]:
```

	A	B
0	1.00000	0.250000
1	2.10000	0.672808
2	3.43454	1.928950
3	4.70000	4.000000
4	5.60000	12.200000
5	6.80000	14.400000

```
In [78]: df.interpolate(method='akima')
```

```
Out[78]:
```

	A	B
0	1.000000	0.250000
1	2.100000	-0.873316
2	3.406667	0.320034
3	4.700000	4.000000
4	5.600000	12.200000
5	6.800000	14.400000

When interpolating via a polynomial or spline approximation, you must also specify the degree or order of the approximation:

```
In [79]: df.interpolate(method='spline', order=2)
```

```
Out[79]:
```

	A	B
0	1.000000	0.250000
1	2.100000	-0.428598
2	3.404545	1.206900
3	4.700000	4.000000
4	5.600000	12.200000
5	6.800000	14.400000

(continues on next page)

(continued from previous page)

```
In [80]: df.interpolate(method='polynomial', order=2)
Out[80]:
      A          B
0  1.000000  0.250000
1  2.100000 -2.703846
2  3.451351 -1.453846
3  4.700000  4.000000
4  5.600000 12.200000
5  6.800000 14.400000
```

Compare several methods:

```
In [81]: np.random.seed(2)

In [82]: ser = pd.Series(np.arange(1, 10.1, .25) ** 2 + np.random.randn(37))

In [83]: missing = np.array([4, 13, 14, 15, 16, 17, 18, 20, 29])

In [84]: ser[missing] = np.nan

In [85]: methods = ['linear', 'quadratic', 'cubic']

In [86]: df = pd.DataFrame({m: ser.interpolate(method=m) for m in methods})

In [87]: df.plot()
Out[87]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d64159650>
```

Another use case is interpolation at *new* values. Suppose you have 100 observations from some distribution. And let's suppose that you're particularly interested in what's happening around the middle. You can mix pandas' `reindex` and `interpolate` methods to interpolate at the new values.

```
In [88]: ser = pd.Series(np.sort(np.random.uniform(size=100)))

# interpolate at new_index
In [89]: new_index = ser.index | pd.Index([49.25, 49.5, 49.75, 50.25, 50.5, 50.75])

In [90]: interp_s = ser.reindex(new_index).interpolate(method='pchip')

In [91]: interp_s[49:51]
Out[91]:
49.00    0.471410
49.25    0.476841
49.50    0.481780
49.75    0.485998
50.00    0.489266
50.25    0.491814
50.50    0.493995
50.75    0.495763
51.00    0.497074
dtype: float64
```

Interpolation limits

Like other pandas fill methods, `interpolate()` accepts a `limit` keyword argument. Use this argument to limit the number of consecutive `NaN` values filled since the last valid observation:

```
In [92]: ser = pd.Series([np.nan, np.nan, 5, np.nan, np.nan,
....:                      np.nan, 13, np.nan, np.nan])
....:

In [93]: ser
Out[93]:
0      NaN
1      NaN
2      5.0
3      NaN
4      NaN
5      NaN
6     13.0
7      NaN
8      NaN
dtype: float64

# fill all consecutive values in a forward direction
In [94]: ser.interpolate()
Out[94]:
0      NaN
1      NaN
2      5.0
3      7.0
4      9.0
5     11.0
6     13.0
7     13.0
8     13.0
dtype: float64

# fill one consecutive value in a forward direction
In [95]: ser.interpolate(limit=1)
Out[95]:
0      NaN
1      NaN
2      5.0
3      7.0
4      NaN
5      NaN
6     13.0
7     13.0
8      NaN
dtype: float64
```

By default, `NaN` values are filled in a `forward` direction. Use `limit_direction` parameter to fill `backward` or from both directions.

```
# fill one consecutive value backwards
In [96]: ser.interpolate(limit=1, limit_direction='backward')
Out[96]:
0      NaN
1      5.0
```

(continues on next page)

(continued from previous page)

```

2      5.0
3      NaN
4      NaN
5     11.0
6     13.0
7      NaN
8      NaN
dtype: float64

# fill one consecutive value in both directions
In [97]: ser.interpolate(limit=1, limit_direction='both')
Out[97]:
0      NaN
1      5.0
2      5.0
3      7.0
4      NaN
5     11.0
6     13.0
7     13.0
8      NaN
dtype: float64

# fill all consecutive values in both directions
In [98]: ser.interpolate(limit_direction='both')
Out[98]:
0      5.0
1      5.0
2      5.0
3      7.0
4      9.0
5     11.0
6     13.0
7     13.0
8     13.0
dtype: float64

```

By default, NaN values are filled whether they are inside (surrounded by) existing valid values, or outside existing valid values. Introduced in v0.23 the `limit_area` parameter restricts filling to either inside or outside values.

```

# fill one consecutive inside value in both directions
In [99]: ser.interpolate(limit_direction='both', limit_area='inside', limit=1)
Out[99]:
0      NaN
1      NaN
2      5.0
3      7.0
4      NaN
5     11.0
6     13.0
7      NaN
8      NaN
dtype: float64

# fill all consecutive outside values backward
In [100]: ser.interpolate(limit_direction='backward', limit_area='outside')

```

(continues on next page)

(continued from previous page)

```
Out[100]:  
0    5.0  
1    5.0  
2    5.0  
3    NaN  
4    NaN  
5    NaN  
6    13.0  
7    NaN  
8    NaN  
dtype: float64  
  
# fill all consecutive outside values in both directions  
In [101]: ser.interpolate(limit_direction='both', limit_area='outside')  
Out[101]:  
0    5.0  
1    5.0  
2    5.0  
3    NaN  
4    NaN  
5    NaN  
6    13.0  
7    13.0  
8    13.0  
dtype: float64
```

3.7.10 Replacing generic values

Often times we want to replace arbitrary values with other values.

`replace()` in Series and `replace()` in DataFrame provides an efficient yet flexible way to perform such replacements.

For a Series, you can replace a single value or a list of values by another value:

```
In [102]: ser = pd.Series([0., 1., 2., 3., 4.])  
  
In [103]: ser.replace(0, 5)  
Out[103]:  
0    5.0  
1    1.0  
2    2.0  
3    3.0  
4    4.0  
dtype: float64
```

You can replace a list of values by a list of other values:

```
In [104]: ser.replace([0, 1, 2, 3, 4], [4, 3, 2, 1, 0])  
Out[104]:  
0    4.0  
1    3.0  
2    2.0  
3    1.0  
4    0.0  
dtype: float64
```

You can also specify a mapping dict:

```
In [105]: ser.replace({0: 10, 1: 100})
Out[105]:
0    10.0
1   100.0
2    2.0
3    3.0
4    4.0
dtype: float64
```

For a DataFrame, you can specify individual values by column:

```
In [106]: df = pd.DataFrame({'a': [0, 1, 2, 3, 4], 'b': [5, 6, 7, 8, 9]})

In [107]: df.replace({'a': 0, 'b': 5}, 100)
Out[107]:
     a    b
0  100  100
1    1    6
2    2    7
3    3    8
4    4    9
```

Instead of replacing with specified values, you can treat all given values as missing and interpolate over them:

```
In [108]: ser.replace([1, 2, 3], method='pad')
Out[108]:
0    0.0
1    0.0
2    0.0
3    0.0
4    4.0
dtype: float64
```

3.7.11 String/regular expression replacement

Note: Python strings prefixed with the `r` character such as `r'hello world'` are so-called “raw” strings. They have different semantics regarding backslashes than strings without this prefix. Backslashes in raw strings will be interpreted as an escaped backslash, e.g., `r'\\' == '\\\\'`. You should [read about them](#) if this is unclear.

Replace the ‘.’ with NaN (str -> str):

```
In [109]: d = {'a': list(range(4)), 'b': list('ab..'), 'c': ['a', 'b', np.nan, 'd']}
In [110]: df = pd.DataFrame(d)

In [111]: df.replace('.', np.nan)
Out[111]:
     a    b    c
0    0    a    a
1    1    b    b
2    2  NaN  NaN
3    3  NaN    d
```

Now do it with a regular expression that removes surrounding whitespace (regex -> regex):

```
In [112]: df.replace(r'\s*\.\s*', np.nan, regex=True)
Out[112]:
   a     b     c
0  0     a     a
1  1     b     b
2  2    NaN    NaN
3  3    NaN     d
```

Replace a few different values (list -> list):

```
In [113]: df.replace(['a', '.'], ['b', np.nan])
Out[113]:
   a     b     c
0  0     b     b
1  1     b     b
2  2    NaN    NaN
3  3    NaN     d
```

list of regex -> list of regex:

```
In [114]: df.replace([r'\.', r'(a)'], ['dot', r'\1stuff'], regex=True)
Out[114]:
   a         b         c
0  0  astuff  astuff
1  1         b         b
2  2    dot      NaN
3  3    dot      d
```

Only search in column 'b' (dict -> dict):

```
In [115]: df.replace({'b': '.'}, {'b': np.nan})
Out[115]:
   a     b     c
0  0     a     a
1  1     b     b
2  2    NaN    NaN
3  3    NaN     d
```

Same as the previous example, but use a regular expression for searching instead (dict of regex -> dict):

```
In [116]: df.replace({'b': r'\s*\.\s*'}, {'b': np.nan}, regex=True)
Out[116]:
   a     b     c
0  0     a     a
1  1     b     b
2  2    NaN    NaN
3  3    NaN     d
```

You can pass nested dictionaries of regular expressions that use `regex=True`:

```
In [117]: df.replace({'b': {'b': r''}}, regex=True)
Out[117]:
   a     b     c
0  0     a     a
1  1         b
```

(continues on next page)

(continued from previous page)

```
2 2 . NaN
3 3 . d
```

Alternatively, you can pass the nested dictionary like so:

```
In [118]: df.replace(regex={'b': {r'\s*\.\s*': np.nan}})

Out[118]:
   a   b   c
0 0   a   a
1 1   b   b
2 2  NaN  NaN
3 3  NaN  d
```

You can also use the group of a regular expression match when replacing (dict of regex -> dict of regex), this works for lists as well.

```
In [119]: df.replace({'b': r'\s*(\.)\s*', 'b': r'\1ty'}, regex=True)

Out[119]:
   a   b   c
0 0   a   a
1 1   b   b
2 2  .ty  NaN
3 3  .ty  d
```

You can pass a list of regular expressions, of which those that match will be replaced with a scalar (list of regex -> regex).

```
In [120]: df.replace([r'\s*\.\s*', r'a|b'], np.nan, regex=True)

Out[120]:
   a   b   c
0 0  NaN  NaN
1 1  NaN  NaN
2 2  NaN  NaN
3 3  NaN  d
```

All of the regular expression examples can also be passed with the `to_replace` argument as the `regex` argument. In this case the `value` argument must be passed explicitly by name or `regex` must be a nested dictionary. The previous example, in this case, would then be:

```
In [121]: df.replace(regex=[r'\s*\.\s*', r'a|b'], value=np.nan)

Out[121]:
   a   b   c
0 0  NaN  NaN
1 1  NaN  NaN
2 2  NaN  NaN
3 3  NaN  d
```

This can be convenient if you do not want to pass `regex=True` every time you want to use a regular expression.

Note: Anywhere in the above `replace` examples that you see a regular expression a compiled regular expression is valid as well.

3.7.12 Numeric replacement

`replace()` is similar to `fillna()`.

```
In [122]: df = pd.DataFrame(np.random.randn(10, 2))

In [123]: df[np.random.rand(df.shape[0]) > 0.5] = 1.5

In [124]: df.replace(1.5, np.nan)
Out[124]:
      0      1
0 -0.844214 -1.021415
1  0.432396 -0.323580
2  0.423825  0.799180
3  1.262614  0.751965
4      NaN      NaN
5      NaN      NaN
6 -0.498174 -1.060799
7  0.591667 -0.183257
8  1.019855 -1.482465
9      NaN      NaN
```

Replacing more than one value is possible by passing a list.

```
In [125]: df00 = df.iloc[0, 0]

In [126]: df.replace([1.5, df00], [np.nan, 'a'])
Out[126]:
      0      1
0      a -1.02141
1  0.432396 -0.32358
2  0.423825  0.79918
3  1.26261  0.751965
4      NaN      NaN
5      NaN      NaN
6 -0.498174 -1.0608
7  0.591667 -0.183257
8  1.01985 -1.48247
9      NaN      NaN

In [127]: df[1].dtype
Out[127]: dtype('float64')
```

You can also operate on the DataFrame in place:

```
In [128]: df.replace(1.5, np.nan, inplace=True)
```

Warning: When replacing multiple `bool` or `datetime64` objects, the first argument to `replace` (`to_replace`) must match the type of the value being replaced. For example,

```
>>> s = pd.Series([True, False, True])
>>> s.replace({'a string': 'new value', True: False}) # raises
TypeError: Cannot compare types 'ndarray(dtype=bool)' and 'str'
```

will raise a `TypeError` because one of the dict keys is not of the correct type for replacement.

However, when replacing a *single* object such as,

```
In [129]: s = pd.Series([True, False, True])

In [130]: s.replace('a string', 'another string')
Out[130]:
0    True
1    False
2    True
dtype: bool
```

the original NDFrame object will be returned untouched. We're working on unifying this API, but for backwards compatibility reasons we cannot break the latter behavior. See [GH6354](#) for more details.

Missing data casting rules and indexing

While pandas supports storing arrays of integer and boolean type, these types are not capable of storing missing data. Until we can switch to using a native NA type in NumPy, we've established some “casting rules”. When a reindexing operation introduces missing data, the Series will be cast according to the rules introduced in the table below.

data type	Cast to
integer	float
boolean	object
float	no cast
object	no cast

For example:

```
In [131]: s = pd.Series(np.random.randn(5), index=[0, 2, 4, 6, 7])

In [132]: s > 0
Out[132]:
0    True
2    True
4    True
6    True
7    True
dtype: bool

In [133]: (s > 0).dtype
Out[133]: dtype('bool')

In [134]: crit = (s > 0).reindex(list(range(8)))

In [135]: crit
Out[135]:
0    True
1    NaN
2    True
3    NaN
4    True
5    NaN
6    True
7    True
dtype: object
```

(continues on next page)

(continued from previous page)

```
In [136]: crit.dtype
Out[136]: dtype('O')
```

Ordinarily NumPy will complain if you try to use an object array (even if it contains boolean values) instead of a boolean array to get or set values from an ndarray (e.g. selecting values based on some criteria). If a boolean vector contains NAs, an exception will be generated:

```
In [137]: reindexed = s.reindex(list(range(8))).fillna(0)

In [138]: reindexed[crit]
-----
ValueError                                                 Traceback (most recent call last)
<ipython-input-138-0dac417a4890> in <module>
----> 1 reindexed[crit]

/pandas/pandas/core/series.py in __getitem__(self, key)
    905         key = list(key)
    906
--> 907     if com.is_bool_indexer(key):
    908         key = check_bool_indexer(self.index, key)
    909

/pandas/pandas/core/common.py in is_bool_indexer(key)
    134         if not lib.is_bool_array(key):
    135             if isna(key).any():
--> 136                 raise ValueError(na_msg)
    137             return False
    138         return True

ValueError: cannot mask with array containing NA / NaN values
```

However, these can be filled in using `fillna()` and it will work fine:

```
In [139]: reindexed[crit.fillna(False)]
Out[139]:
0    0.126504
2    0.696198
4    0.697416
6    0.601516
7    0.003659
dtype: float64

In [140]: reindexed[crit.fillna(True)]
Out[140]:
0    0.126504
1    0.000000
2    0.696198
3    0.000000
4    0.697416
5    0.000000
6    0.601516
7    0.003659
dtype: float64
```

Pandas provides a nullable integer dtype, but you must explicitly request it when creating the series or column. Notice that we use a capital “I” in the `dtype="Int64"`.

```
In [141]: s = pd.Series([0, 1, np.nan, 3, 4], dtype="Int64")

In [142]: s
Out[142]:
0      0
1      1
2    <NA>
3      3
4      4
dtype: Int64
```

See [Nullable integer data type](#) for more.

3.7.13 Experimental NA scalar to denote missing values

Warning: Experimental: the behaviour of `pd.NA` can still change without warning.

New in version 1.0.0.

Starting from pandas 1.0, an experimental `pd.NA` value (singleton) is available to represent scalar missing values. At this moment, it is used in the nullable [integer](#), boolean and [dedicated string](#) data types as the missing value indicator.

The goal of `pd.NA` is provide a “missing” indicator that can be used consistently across data types (instead of `np.nan`, `None` or `pd.NaT` depending on the data type).

For example, when having missing values in a Series with the nullable integer dtype, it will use `pd.NA`:

```
In [143]: s = pd.Series([1, 2, None], dtype="Int64")

In [144]: s
Out[144]:
0      1
1      2
2    <NA>
dtype: Int64

In [145]: s[2]
Out[145]: <NA>

In [146]: s[2] is pd.NA
Out[146]: True
```

Currently, pandas does not yet use those data types by default (when creating a DataFrame or Series, or when reading in data), so you need to specify the dtype explicitly. An easy way to convert to those dtypes is explained [here](#).

Propagation in arithmetic and comparison operations

In general, missing values *propagate* in operations involving `pd.NA`. When one of the operands is unknown, the outcome of the operation is also unknown.

For example, `pd.NA` propagates in arithmetic operations, similarly to `np.nan`:

```
In [147]: pd.NA + 1
Out[147]: <NA>

In [148]: "a" * pd.NA
Out[148]: <NA>
```

There are a few special cases when the result is known, even when one of the operands is NA.

```
In [149]: pd.NA ** 0
Out[149]: 1

In [150]: 1 ** pd.NA
Out[150]: 1
```

In equality and comparison operations, `pd.NA` also propagates. This deviates from the behaviour of `np.nan`, where comparisons with `np.nan` always return `False`.

```
In [151]: pd.NA == 1
Out[151]: <NA>

In [152]: pd.NA == pd.NA
Out[152]: <NA>

In [153]: pd.NA < 2.5
Out[153]: <NA>
```

To check if a value is equal to `pd.NA`, the `isna()` function can be used:

```
In [154]: pd.isna(pd.NA)
Out[154]: True
```

An exception on this basic propagation rule are *reductions* (such as the mean or the minimum), where pandas defaults to skipping missing values. See [above](#) for more.

Logical operations

For logical operations, `pd.NA` follows the rules of the [three-valued logic](#) (or *Kleene logic*, similarly to R, SQL and Julia). This logic means to only propagate missing values when it is logically required.

For example, for the logical “or” operation (`|`), if one of the operands is `True`, we already know the result will be `True`, regardless of the other value (so regardless the missing value would be `True` or `False`). In this case, `pd.NA` does not propagate:

```
In [155]: True | False
Out[155]: True

In [156]: True | pd.NA
Out[156]: True
```

(continues on next page)

(continued from previous page)

```
In [157]: pd.NA | True
Out[157]: True
```

On the other hand, if one of the operands is `False`, the result depends on the value of the other operand. Therefore, in this case `pd.NA` propagates:

```
In [158]: False | True
Out[158]: True

In [159]: False | False
Out[159]: False

In [160]: False | pd.NA
Out[160]: <NA>
```

The behaviour of the logical “and” operation (`&`) can be derived using similar logic (where now `pd.NA` will not propagate if one of the operands is already `False`):

```
In [161]: False & True
Out[161]: False

In [162]: False & False
Out[162]: False

In [163]: False & pd.NA
Out[163]: False
```

```
In [164]: True & True
Out[164]: True

In [165]: True & False
Out[165]: False

In [166]: True & pd.NA
Out[166]: <NA>
```

NA in a boolean context

Since the actual value of an NA is unknown, it is ambiguous to convert NA to a boolean value. The following raises an error:

```
In [167]: bool(pd.NA)
-----
TypeError                                         Traceback (most recent call last)
<ipython-input-167-5477a57d5abb> in <module>
----> 1 bool(pd.NA)

/pandas/pandas/_libs/missing.pyx in pandas._libs.missing.NAType.__bool__()

TypeError: boolean value of NA is ambiguous
```

This also means that `pd.NA` cannot be used in a context where it is evaluated to a boolean, such as `if condition: ...` where `condition` can potentially be `pd.NA`. In such cases, `isna()` can be used to check for `pd.NA` or `condition` being `pd.NA` can be avoided, for example by filling missing values beforehand.

A similar situation occurs when using Series or DataFrame objects in `if` statements, see [Using if/truth statements with pandas](#).

NumPy ufuncs

`pandas.NA` implements NumPy's `__array_ufunc__` protocol. Most ufuncs work with NA, and generally return NA:

```
In [168]: np.log(pd.NA)
Out[168]: <NA>

In [169]: np.add(pd.NA, 1)
Out[169]: <NA>
```

Warning: Currently, ufuncs involving an ndarray and NA will return an object-dtype filled with NA values.

```
In [170]: a = np.array([1, 2, 3])

In [171]: np.greater(a, pd.NA)
Out[171]: array([<NA>, <NA>, <NA>], dtype=object)
```

The return type here may change to return a different array type in the future.

See [DataFrame interoperability with NumPy functions](#) for more on ufuncs.

Conversion

If you have a DataFrame or Series using traditional types that have missing data represented using `np.nan`, there are convenience methods `convert_dtypes()` in Series and `convert_dtypes()` in DataFrame that can convert data to use the newer dtypes for integers, strings and booleans listed [here](#). This is especially helpful after reading in data sets when letting the readers such as `read_csv()` and `read_excel()` infer default dtypes.

In this example, while the dtypes of all columns are changed, we show the results for the first 10 columns.

```
In [172]: bb = pd.read_csv('data/baseball.csv', index_col='id')

In [173]: bb[bb.columns[:10]].dtypes
Out[173]:
player      object
year        int64
stint       int64
team        object
lg          object
g           int64
ab           int64
r            int64
h            int64
x2b          int64
dtype: object
```

```
In [174]: bbn = bb.convert_dtypes()

In [175]: bbn[bbn.columns[:10]].dtypes
Out[175]:
```

(continues on next page)

(continued from previous page)

```

player      string
year       Int64
stint      Int64
team       string
lg         string
g          Int64
ab         Int64
r          Int64
h          Int64
X2b        Int64
dtype: object

```

{{ header }}

3.8 Categorical data

This is an introduction to pandas categorical data type, including a short comparison with R's `factor`.

Categoricals are a pandas data type corresponding to categorical variables in statistics. A categorical variable takes on a limited, and usually fixed, number of possible values (*categories*; *levels* in R). Examples are gender, social class, blood type, country affiliation, observation time or rating via Likert scales.

In contrast to statistical categorical variables, categorical data might have an order (e.g. ‘strongly agree’ vs ‘agree’ or ‘first observation’ vs. ‘second observation’), but numerical operations (additions, divisions, ...) are not possible.

All values of categorical data are either in *categories* or *np.nan*. Order is defined by the order of *categories*, not lexical order of the values. Internally, the data structure consists of a *categories* array and an integer array of *codes* which point to the real value in the *categories* array.

The categorical data type is useful in the following cases:

- A string variable consisting of only a few different values. Converting such a string variable to a categorical variable will save some memory, see [here](#).
- The lexical order of a variable is not the same as the logical order (“one”, “two”, “three”). By converting to a categorical and specifying an order on the categories, sorting and min/max will use the logical order instead of the lexical order, see [here](#).
- As a signal to other Python libraries that this column should be treated as a categorical variable (e.g. to use suitable statistical methods or plot types).

See also the [API docs on categoricals](#).

3.8.1 Object creation

Series creation

Categorical Series or columns in a DataFrame can be created in several ways:

By specifying `dtype="category"` when constructing a Series:

```

In [1]: s = pd.Series(["a", "b", "c", "a"], dtype="category")
In [2]: s
Out[2]:

```

(continues on next page)

(continued from previous page)

```
0    a
1    b
2    c
3    a
dtype: category
Categories (3, object): [a, b, c]
```

By converting an existing Series or column to a category dtype:

```
In [3]: df = pd.DataFrame({'A': ["a", "b", "c", "a"]})

In [4]: df["B"] = df["A"].astype('category')

In [5]: df
Out[5]:
   A   B
0  a  a
1  b  b
2  c  c
3  a  a
```

By using special functions, such as `cut()`, which groups data into discrete bins. See the [example on tiling](#) in the docs.

```
In [6]: df = pd.DataFrame({'value': np.random.randint(0, 100, 20)})

In [7]: labels = ["{} - {}".format(i, i + 9) for i in range(0, 100, 10)]

In [8]: df['group'] = pd.cut(df.value, range(0, 105, 10), right=False, labels=labels)

In [9]: df.head(10)
Out[9]:
   value      group
0     90  90 - 99
1     91  90 - 99
2     26  20 - 29
3     48  40 - 49
4     74  70 - 79
5     44  40 - 49
6     78  70 - 79
7     96  90 - 99
8     36  30 - 39
9     93  90 - 99
```

By passing a `pandas.Categorical` object to a Series or assigning it to a DataFrame.

```
In [10]: raw_cat = pd.Categorical(["a", "b", "c", "a"], categories=["b", "c", "d"],
.....:                      ordered=False)
.....:

In [11]: s = pd.Series(raw_cat)

In [12]: s
Out[12]:
0      NaN
1        b
```

(continues on next page)

(continued from previous page)

```

2      c
3    NaN
dtype: category
Categories (3, object): [b, c, d]

In [13]: df = pd.DataFrame({ "A": [ "a", "b", "c", "a" ] })

In [14]: df[ "B" ] = raw_cat

In [15]: df
Out[15]:
   A    B
0  a  NaN
1  b    b
2  c    c
3  a  NaN

```

Categorical data has a specific category *dtype*:

```

In [16]: df.dtypes
Out[16]:
A    object
B    category
dtype: object

```

DataFrame creation

Similar to the previous section where a single column was converted to categorical, all columns in a DataFrame can be batch converted to categorical either during or after construction.

This can be done during construction by specifying `dtype="category"` in the `DataFrame` constructor:

```

In [17]: df = pd.DataFrame({ 'A': list('abca'), 'B': list('bccd') }, dtype="category")

In [18]: df.dtypes
Out[18]:
A    category
B    category
dtype: object

```

Note that the categories present in each column differ; the conversion is done column by column, so only labels present in a given column are categories:

```

In [19]: df[ 'A' ]
Out[19]:
0    a
1    b
2    c
3    a
Name: A, dtype: category
Categories (3, object): [a, b, c]

In [20]: df[ 'B' ]
Out[20]:
0    b

```

(continues on next page)

(continued from previous page)

```
1    c
2    c
3    d
Name: B, dtype: category
Categories (3, object): [b, c, d]
```

New in version 0.23.0.

Analogously, all columns in an existing DataFrame can be batch converted using DataFrame.astype():

```
In [21]: df = pd.DataFrame({'A': list('abca'), 'B': list('bccd')})

In [22]: df_cat = df.astype('category')

In [23]: df_cat.dtypes
Out[23]:
A    category
B    category
dtype: object
```

This conversion is likewise done column by column:

```
In [24]: df_cat['A']
Out[24]:
0    a
1    b
2    c
3    a
Name: A, dtype: category
Categories (3, object): [a, b, c]

In [25]: df_cat['B']
Out[25]:
0    b
1    c
2    c
3    d
Name: B, dtype: category
Categories (3, object): [b, c, d]
```

Controlling behavior

In the examples above where we passed `dtype='category'`, we used the default behavior:

1. Categories are inferred from the data.
2. Categories are unordered.

To control those behaviors, instead of passing '`category`', use an instance of `CategoricalDtype`.

```
In [26]: from pandas.api.types import CategoricalDtype

In [27]: s = pd.Series(["a", "b", "c", "a"])

In [28]: cat_type = CategoricalDtype(categories=["b", "c", "d"],
.....:           ordered=True)
```

(continues on next page)

(continued from previous page)

```
....:

In [29]: s_cat = s.astype(cat_type)

In [30]: s_cat
Out[30]:
0      NaN
1        b
2        c
3      NaN
dtype: category
Categories (3, object): [b < c < d]
```

Similarly, a CategoricalDtype can be used with a DataFrame to ensure that categories are consistent among all columns.

```
In [31]: from pandas.api.types import CategoricalDtype

In [32]: df = pd.DataFrame({'A': list('abca'), 'B': list('bccd')})

In [33]: cat_type = CategoricalDtype(categories=list('abcd'),
...:                               ordered=True)
...:

In [34]: df_cat = df.astype(cat_type)

In [35]: df_cat['A']
Out[35]:
0    a
1    b
2    c
3    a
Name: A, dtype: category
Categories (4, object): [a < b < c < d]

In [36]: df_cat['B']
Out[36]:
0    b
1    c
2    c
3    d
Name: B, dtype: category
Categories (4, object): [a < b < c < d]
```

Note: To perform table-wise conversion, where all labels in the entire DataFrame are used as categories for each column, the categories parameter can be determined programmatically by categories = pd.unique(df.to_numpy().ravel()).

If you already have codes and categories, you can use the `from_codes()` constructor to save the factorize step during normal constructor mode:

```
In [37]: splitter = np.random.choice([0, 1], 5, p=[0.5, 0.5])

In [38]: s = pd.Series(pd.Categorical.from_codes(splitter,
```

(continues on next page)

(continued from previous page)

```
....: categories=["train", "test"]))  
....:
```

Regaining original data

To get back to the original Series or NumPy array, use `Series.astype(original_dtype)` or `np.asarray(categorical)`:

```
In [39]: s = pd.Series(["a", "b", "c", "a")  
  
In [40]: s  
Out[40]:  
0    a  
1    b  
2    c  
3    a  
dtype: object  
  
In [41]: s2 = s.astype('category')  
  
In [42]: s2  
Out[42]:  
0    a  
1    b  
2    c  
3    a  
dtype: category  
Categories (3, object): [a, b, c]  
  
In [43]: s2.astype(str)  
Out[43]:  
0    a  
1    b  
2    c  
3    a  
dtype: object  
  
In [44]: np.asarray(s2)  
Out[44]: array(['a', 'b', 'c', 'a'], dtype=object)
```

Note: In contrast to R's `factor` function, categorical data is not converting input values to strings; categories will end up the same data type as the original values.

Note: In contrast to R's `factor` function, there is currently no way to assign/change labels at creation time. Use `categories` to change the categories after creation time.

3.8.2 CategoricalDtype

Changed in version 0.21.0.

A categorical's type is fully described by

1. categories: a sequence of unique values and no missing values
2. ordered: a boolean

This information can be stored in a `CategoricalDtype`. The `categories` argument is optional, which implies that the actual categories should be inferred from whatever is present in the data when the `pandas.Categorical` is created. The categories are assumed to be unordered by default.

```
In [45]: from pandas.api.types import CategoricalDtype
In [46]: CategoricalDtype(['a', 'b', 'c'])
Out[46]: CategoricalDtype(categories=['a', 'b', 'c'], ordered=False)
In [47]: CategoricalDtype(['a', 'b', 'c'], ordered=True)
Out[47]: CategoricalDtype(categories=['a', 'b', 'c'], ordered=True)
In [48]: CategoricalDtype()
Out[48]: CategoricalDtype(categories=None, ordered=False)
```

A `CategoricalDtype` can be used in any place pandas expects a `dtype`. For example `pandas.read_csv()`, `pandas.DataFrame.astype()`, or in the `Series` constructor.

Note: As a convenience, you can use the string '`category`' in place of a `CategoricalDtype` when you want the default behavior of the categories being unordered, and equal to the set values present in the array. In other words, `dtype='category'` is equivalent to `dtype=CategoricalDtype()`.

Equality semantics

Two instances of `CategoricalDtype` compare equal whenever they have the same categories and order. When comparing two unordered categoricals, the order of the categories is not considered.

```
In [49]: c1 = CategoricalDtype(['a', 'b', 'c'], ordered=False)
# Equal, since order is not considered when ordered=False
In [50]: c1 == CategoricalDtype(['b', 'c', 'a'], ordered=False)
Out[50]: True

# Unequal, since the second CategoricalDtype is ordered
In [51]: c1 == CategoricalDtype(['a', 'b', 'c'], ordered=True)
Out[51]: False
```

All instances of `CategoricalDtype` compare equal to the string '`category`'.

```
In [52]: c1 == 'category'
Out[52]: True
```

Warning: Since `dtype='category'` is essentially `CategoricalDtype(None, False)`, and since all instances `CategoricalDtype` compare equal to '`category`', all instances of `CategoricalDtype` compare equal to a `CategoricalDtype(None, False)`, regardless of categories or ordered.

3.8.3 Description

Using `describe()` on categorical data will produce similar output to a `Series` or `DataFrame` of type `string`.

```
In [53]: cat = pd.Categorical(["a", "c", "c", np.nan], categories=["b", "a", "c"])

In [54]: df = pd.DataFrame({"cat": cat, "s": ["a", "c", "c", np.nan]})

In [55]: df.describe()
Out[55]:
    cat      s
count    3    3
unique   2    2
top      c    c
freq     2    2

In [56]: df["cat"].describe()
Out[56]:
count    3
unique   2
top      c
freq     2
Name: cat, dtype: object
```

3.8.4 Working with categories

Categorical data has a `categories` and a `ordered` property, which list their possible values and whether the ordering matters or not. These properties are exposed as `s.cat.categories` and `s.cat.ordered`. If you don't manually specify categories and ordering, they are inferred from the passed arguments.

```
In [57]: s = pd.Series(["a", "b", "c", "a"], dtype="category")

In [58]: s.cat.categories
Out[58]: Index(['a', 'b', 'c'], dtype='object')

In [59]: s.cat.ordered
Out[59]: False
```

It's also possible to pass in the categories in a specific order:

```
In [60]: s = pd.Series(pd.Categorical(["a", "b", "c", "a"],
.....:                 categories=["c", "b", "a"]))
.....:

In [61]: s.cat.categories
Out[61]: Index(['c', 'b', 'a'], dtype='object')

In [62]: s.cat.ordered
Out[62]: False
```

Note: New categorical data are **not** automatically ordered. You must explicitly pass `ordered=True` to indicate an ordered Categorical.

Note: The result of `unique()` is not always the same as `Series.cat.categories`, because `Series.unique()` has a couple of guarantees, namely that it returns categories in the order of appearance, and it only includes values that are actually present.

```
In [63]: s = pd.Series(list('babc')).astype(CategoricalDtype(list('abcd')))

In [64]: s
Out[64]:
0    b
1    a
2    b
3    c
dtype: category
Categories (4, object): [a, b, c, d]

# categories
In [65]: s.cat.categories
Out[65]: Index(['a', 'b', 'c', 'd'], dtype='object')

# uniques
In [66]: s.unique()
Out[66]:
[b, a, c]
Categories (3, object): [b, a, c]
```

Renaming categories

Renaming categories is done by assigning new values to the `Series.cat.categories` property or by using the `rename_categories()` method:

```
In [67]: s = pd.Series(["a", "b", "c", "a"], dtype="category")

In [68]: s
Out[68]:
0    a
1    b
2    c
3    a
dtype: category
Categories (3, object): [a, b, c]

In [69]: s.cat.categories = ["Group %s" % g for g in s.cat.categories]

In [70]: s
Out[70]:
0    Group a
1    Group b
2    Group c
3    Group a
```

(continues on next page)

(continued from previous page)

```
dtype: category
Categories (3, object): [Group a, Group b, Group c]

In [71]: s = s.cat.rename_categories([1, 2, 3])

In [72]: s
Out[72]:
0    1
1    2
2    3
3    1
dtype: category
Categories (3, int64): [1, 2, 3]

# You can also pass a dict-like object to map the renaming
In [73]: s = s.cat.rename_categories({1: 'x', 2: 'y', 3: 'z'})

In [74]: s
Out[74]:
0    x
1    y
2    z
3    x
dtype: category
Categories (3, object): [x, y, z]
```

Note: In contrast to R's *factor*, categorical data can have categories of other types than string.

Note: Be aware that assigning new categories is an inplace operation, while most other operations under Series.cat per default return a new Series of dtype *category*.

Categories must be unique or a *ValueError* is raised:

```
In [75]: try:
.....    s.cat.categories = [1, 1, 1]
.....    except ValueError as e:
.....        print("ValueError:", str(e))
.....
ValueError: Categorical categories must be unique
```

Categories must also not be NaN or a *ValueError* is raised:

```
In [76]: try:
.....    s.cat.categories = [1, 2, np.nan]
.....    except ValueError as e:
.....        print("ValueError:", str(e))
.....
ValueError: Categorical categories cannot be null
```

Appending new categories

Appending categories can be done by using the `add_categories()` method:

```
In [77]: s = s.cat.add_categories([4])

In [78]: s.cat.categories
Out[78]: Index(['x', 'y', 'z', 4], dtype='object')

In [79]: s
Out[79]:
0    x
1    y
2    z
3    x
dtype: category
Categories (4, object): [x, y, z, 4]
```

Removing categories

Removing categories can be done by using the `remove_categories()` method. Values which are removed are replaced by `np.nan`:

```
In [80]: s = s.cat.remove_categories([4])

In [81]: s
Out[81]:
0    x
1    y
2    z
3    x
dtype: category
Categories (3, object): [x, y, z]
```

Removing unused categories

Removing unused categories can also be done:

```
In [82]: s = pd.Series(pd.Categorical(["a", "b", "a"],
...                                 categories=["a", "b", "c", "d"]))
....:
....:

In [83]: s
Out[83]:
0    a
1    b
2    a
dtype: category
Categories (4, object): [a, b, c, d]

In [84]: s.cat.remove_unused_categories()
Out[84]:
0    a
1    b
2    a
```

(continues on next page)

(continued from previous page)

```
dtype: category  
Categories (2, object): [a, b]
```

Setting categories

If you want to do remove and add new categories in one step (which has some speed advantage), or simply set the categories to a predefined scale, use `set_categories()`.

```
In [85]: s = pd.Series(["one", "two", "four", "-"], dtype="category")  
  
In [86]: s  
Out[86]:  
0    one  
1    two  
2    four  
3    -  
dtype: category  
Categories (4, object): [-, four, one, two]  
  
In [87]: s = s.cat.set_categories(["one", "two", "three", "four"])  
  
In [88]: s  
Out[88]:  
0    one  
1    two  
2    four  
3    NaN  
dtype: category  
Categories (4, object): [one, two, three, four]
```

Note: Be aware that `Categorical.set_categories()` cannot know whether some category is omitted intentionally or because it is misspelled or (under Python3) due to a type difference (e.g., NumPy S1 dtype and Python strings). This can result in surprising behaviour!

3.8.5 Sorting and order

If categorical data is ordered (`s.cat.ordered == True`), then the order of the categories has a meaning and certain operations are possible. If the categorical is unordered, `.min()` / `.max()` will raise a `TypeError`.

```
In [89]: s = pd.Series(pd.Categorical(["a", "b", "c", "a"], ordered=False))  
  
In [90]: s.sort_values(inplace=True)  
  
In [91]: s = pd.Series(["a", "b", "c", "a"]).astype(  
.....:     CategoricalDtype(ordered=True)  
.....: )  
.....:  
  
In [92]: s.sort_values(inplace=True)  
  
In [93]: s
```

(continues on next page)

(continued from previous page)

```
Out[93]:
0    a
3    a
1    b
2    c
dtype: category
Categories (3, object): [a < b < c]

In [94]: s.min(), s.max()
Out[94]: ('a', 'c')
```

You can set categorical data to be ordered by using `as_ordered()` or unordered by using `as_unordered()`. These will by default return a *new* object.

```
In [95]: s.cat.as_ordered()
Out[95]:
0    a
3    a
1    b
2    c
dtype: category
Categories (3, object): [a < b < c]

In [96]: s.cat.as_unordered()
Out[96]:
0    a
3    a
1    b
2    c
dtype: category
Categories (3, object): [a, b, c]
```

Sorting will use the order defined by categories, not any lexical order present on the data type. This is even true for strings and numeric data:

```
In [97]: s = pd.Series([1, 2, 3, 1], dtype="category")

In [98]: s = s.cat.set_categories([2, 3, 1], ordered=True)

In [99]: s
Out[99]:
0    1
1    2
2    3
3    1
dtype: category
Categories (3, int64): [2 < 3 < 1]

In [100]: s.sort_values(inplace=True)

In [101]: s
Out[101]:
1    2
2    3
0    1
3    1
```

(continues on next page)

(continued from previous page)

```
dtype: category
Categories (3, int64): [2 < 3 < 1]

In [102]: s.min(), s.max()
Out[102]: (2, 1)
```

Reordering

Reordering the categories is possible via the `Categorical.reorder_categories()` and the `Categorical.set_categories()` methods. For `Categorical.reorder_categories()`, all old categories must be included in the new categories and no new categories are allowed. This will necessarily make the sort order the same as the categories order.

```
In [103]: s = pd.Series([1, 2, 3, 1], dtype="category")

In [104]: s = s.cat.reorder_categories([2, 3, 1], ordered=True)

In [105]: s
Out[105]:
0    1
1    2
2    3
3    1
dtype: category
Categories (3, int64): [2 < 3 < 1]

In [106]: s.sort_values(inplace=True)

In [107]: s
Out[107]:
1    2
2    3
0    1
3    1
dtype: category
Categories (3, int64): [2 < 3 < 1]

In [108]: s.min(), s.max()
Out[108]: (2, 1)
```

Note: Note the difference between assigning new categories and reordering the categories: the first renames categories and therefore the individual values in the `Series`, but if the first position was sorted last, the renamed value will still be sorted last. Reordering means that the way values are sorted is different afterwards, but not that individual values in the `Series` are changed.

Note: If the `Categorical` is not ordered, `Series.min()` and `Series.max()` will raise `TypeError`. Numeric operations like `+`, `-`, `*`, `/` and operations based on them (e.g. `Series.median()`, which would need to compute the mean between two values if the length of an array is even) do not work and raise a `TypeError`.

Multi column sorting

A categorical dtypes column will participate in a multi-column sort in a similar manner to other columns. The ordering of the categorical is determined by the `categories` of that column.

```
In [109]: dfs = pd.DataFrame({'A': pd.Categorical(list('bbeebbaa'),
.....:                                         categories=['e', 'a', 'b'],
.....:                                         ordered=True),
.....:                                         'B': [1, 2, 1, 2, 2, 1, 2, 1]})

In [110]: dfs.sort_values(by=['A', 'B'])

Out[110]:
   A   B
2  e  1
3  e  2
7  a  1
6  a  2
0  b  1
5  b  1
1  b  2
4  b  2
```

Reordering the `categories` changes a future sort.

```
In [111]: dfs['A'] = dfs['A'].cat.reorder_categories(['a', 'b', 'e'])

In [112]: dfs.sort_values(by=['A', 'B'])

Out[112]:
   A   B
7  a  1
6  a  2
0  b  1
5  b  1
1  b  2
4  b  2
2  e  1
3  e  2
```

3.8.6 Comparisons

Comparing categorical data with other objects is possible in three cases:

- Comparing equality (`==` and `!=`) to a list-like object (list, Series, array, ...) of the same length as the categorical data.
- All comparisons (`==`, `!=`, `>`, `>=`, `<`, and `<=`) of categorical data to another categorical Series, when `ordered=True` and the `categories` are the same.
- All comparisons of a categorical data to a scalar.

All other comparisons, especially “non-equality” comparisons of two categoricals with different categories or a categorical with any list-like object, will raise a `TypeError`.

Note: Any “non-equality” comparisons of categorical data with a Series, `np.array`, list or categorical data with different categories or ordering will raise a `TypeError` because custom categories ordering could be interpreted

in two ways: one with taking into account the ordering and one without.

```
In [113]: cat = pd.Series([1, 2, 3]).astype(
.....:     CategoricalDtype([3, 2, 1], ordered=True)
.....: )
.....:

In [114]: cat_base = pd.Series([2, 2, 2]).astype(
.....:     CategoricalDtype([3, 2, 1], ordered=True)
.....: )
.....:

In [115]: cat_base2 = pd.Series([2, 2, 2]).astype(
.....:     CategoricalDtype(ordered=True)
.....: )
.....:

In [116]: cat
Out[116]:
0    1
1    2
2    3
dtype: category
Categories (3, int64): [3 < 2 < 1]

In [117]: cat_base
Out[117]:
0    2
1    2
2    2
dtype: category
Categories (3, int64): [3 < 2 < 1]

In [118]: cat_base2
Out[118]:
0    2
1    2
2    2
dtype: category
Categories (1, int64): [2]
```

Comparing to a categorical with the same categories and ordering or to a scalar works:

```
In [119]: cat > cat_base
Out[119]:
0    True
1    False
2    False
dtype: bool

In [120]: cat > 2
Out[120]:
0    True
1    False
2    False
dtype: bool
```

Equality comparisons work with any list-like object of same length and scalars:

```
In [121]: cat == cat_base
Out[121]:
0    False
1    True
2    False
dtype: bool

In [122]: cat == np.array([1, 2, 3])
Out[122]:
0    True
1    True
2    True
dtype: bool

In [123]: cat == 2
Out[123]:
0    False
1    True
2    False
dtype: bool
```

This doesn't work because the categories are not the same:

```
In [124]: try:
.....:     cat > cat_base2
.....: except TypeError as e:
.....:     print("TypeError:", str(e))
.....:
TypeError: Categoricals can only be compared if 'categories' are the same. Categories
are different lengths
```

If you want to do a “non-equality” comparison of a categorical series with a list-like object which is not categorical data, you need to be explicit and convert the categorical data back to the original values:

```
In [125]: base = np.array([1, 2, 3])

In [126]: try:
.....:     cat > base
.....: except TypeError as e:
.....:     print("TypeError:", str(e))
.....:
TypeError: Cannot compare a Categorical for op __gt__ with type <class 'numpy.ndarray'
If you want to compare values, use 'np.asarray(cat) <op> other'.

In [127]: np.asarray(cat) > base
Out[127]: array([False, False, False])
```

When you compare two unordered categoricals with the same categories, the order is not considered:

```
In [128]: c1 = pd.Categorical(['a', 'b'], categories=['a', 'b'], ordered=False)

In [129]: c2 = pd.Categorical(['a', 'b'], categories=['b', 'a'], ordered=False)

In [130]: c1 == c2
Out[130]: array([ True,  True])
```

3.8.7 Operations

Apart from Series.min(), Series.max() and Series.mode(), the following operations are possible with categorical data:

Series methods like Series.value_counts() will use all categories, even if some categories are not present in the data:

```
In [131]: s = pd.Series(pd.Categorical(["a", "b", "c", "c"],  
.....:                 categories=["c", "a", "b", "d"]))  
.....:  
  
In [132]: s.value_counts()  
Out[132]:  
c    2  
b    1  
a    1  
d    0  
dtype: int64
```

Groupby will also show “unused” categories:

```
In [133]: cats = pd.Categorical(["a", "b", "b", "b", "c", "c", "c"],  
.....:                 categories=["a", "b", "c", "d"])  
.....:  
  
In [134]: df = pd.DataFrame({"cats": cats, "values": [1, 2, 2, 2, 3, 4, 5]})  
  
In [135]: df.groupby("cats").mean()  
Out[135]:  
      values  
cats  
a      1.0  
b      2.0  
c      4.0  
d      NaN  
  
In [136]: cats2 = pd.Categorical(["a", "a", "b", "b"], categories=["a", "b", "c"])  
  
In [137]: df2 = pd.DataFrame({"cats": cats2,  
.....:                 "B": ["c", "d", "c", "d"],  
.....:                 "values": [1, 2, 3, 4]})  
.....:  
  
In [138]: df2.groupby(["cats", "B"]).mean()  
Out[138]:  
      values  
cats B  
a   c    1.0  
     d    2.0  
b   c    3.0  
     d    4.0  
c   c    NaN  
     d    NaN
```

Pivot tables:

```
In [139]: raw_cat = pd.Categorical(["a", "a", "b", "b"], categories=["a", "b", "c"])

In [140]: df = pd.DataFrame({"A": raw_cat,
   .....:                 "B": ["c", "d", "c", "d"],
   .....:                 "values": [1, 2, 3, 4]})

In [141]: pd.pivot_table(df, values='values', index=['A', 'B'])

Out[141]:
   values
A B
a c      1
      d      2
b c      3
      d      4
```

3.8.8 Data munging

The optimized pandas data access methods `.loc`, `.iloc`, `.at`, and `.iat`, work as normal. The only difference is the return type (for getting) and that only values already in *categories* can be assigned.

Getting

If the slicing operation returns either a DataFrame or a column of type Series, the category dtype is preserved.

```
In [142]: idx = pd.Index(["h", "i", "j", "k", "l", "m", "n"])

In [143]: cats = pd.Series(["a", "b", "b", "b", "c", "c", "c"],
   .....:             dtype="category", index=idx)
   .....:

In [144]: values = [1, 2, 2, 2, 3, 4, 5]

In [145]: df = pd.DataFrame({"cats": cats, "values": values}, index=idx)

In [146]: df.iloc[2:4, :]
Out[146]:
   cats  values
j     b      2
k     b      2

In [147]: df.iloc[2:4, :].dtypes
Out[147]:
cats      category
values     int64
dtype: object

In [148]: df.loc["h":"j", "cats"]
Out[148]:
h     a
i     b
j     b
Name: cats, dtype: category
Categories (3, object): [a, b, c]
```

(continues on next page)

(continued from previous page)

```
In [149]: df[df["cats"] == "b"]
Out[149]:
   cats  values
i      b      2
j      b      2
k      b      2
```

An example where the category type is not preserved is if you take one single row: the resulting Series is of dtype object:

```
# get the complete "h" row as a Series
In [150]: df.loc["h", :]
Out[150]:
cats      a
values     1
Name: h, dtype: object
```

Returning a single item from categorical data will also return the value, not a categorical of length “1”.

```
In [151]: df.iat[0, 0]
Out[151]: 'a'

In [152]: df["cats"].cat.categories = ["x", "y", "z"]

In [153]: df.at["h", "cats"]    # returns a string
Out[153]: 'x'
```

Note: This is in contrast to R’s *factor* function, where `factor(c(1,2,3)) [1]` returns a single value *factor*.

To get a single value Series of type category, you pass in a list with a single value:

```
In [154]: df.loc[[ "h"], "cats"]
Out[154]:
h      x
Name: cats, dtype: category
Categories (3, object): [x, y, z]
```

String and datetime accessors

The accessors `.dt` and `.str` will work if the `s.cat.categories` are of an appropriate type:

```
In [155]: str_s = pd.Series(list('aabb'))
In [156]: str_cat = str_s.astype('category')
In [157]: str_cat
Out[157]:
0      a
1      a
2      b
3      b
dtype: category
```

(continues on next page)

(continued from previous page)

```
Categories (2, object): [a, b]

In [158]: str_cat.str.contains("a")
Out[158]:
0    True
1    True
2   False
3   False
dtype: bool

In [159]: date_s = pd.Series(pd.date_range('1/1/2015', periods=5))

In [160]: date_cat = date_s.astype('category')

In [161]: date_cat
Out[161]:
0    2015-01-01
1    2015-01-02
2    2015-01-03
3    2015-01-04
4    2015-01-05
dtype: category
Categories (5, datetime64[ns]): [2015-01-01, 2015-01-02, 2015-01-03, 2015-01-04, 2015-01-05]

In [162]: date_cat.dt.day
Out[162]:
0    1
1    2
2    3
3    4
4    5
dtype: int64
```

Note: The returned Series (or DataFrame) is of the same type as if you used the `.str.<method>` / `.dt.<method>` on a Series of that type (and not of type `category`!).

That means, that the returned values from methods and properties on the accessors of a Series and the returned values from methods and properties on the accessors of this Series transformed to one of type `category` will be equal:

```
In [163]: ret_s = str_s.str.contains("a")

In [164]: ret_cat = str_cat.str.contains("a")

In [165]: ret_s.dtype == ret_cat.dtype
Out[165]: True

In [166]: ret_s == ret_cat
Out[166]:
0    True
1    True
2    True
3    True
dtype: bool
```

Note: The work is done on the `categories` and then a new `Series` is constructed. This has some performance implication if you have a `Series` of type `string`, where lots of elements are repeated (i.e. the number of unique elements in the `Series` is a lot smaller than the length of the `Series`). In this case it can be faster to convert the original `Series` to one of type `category` and use `.str.<method>` or `.dt.<property>` on that.

Setting

Setting values in a categorical column (or `Series`) works as long as the value is included in the *categories*:

```
In [167]: idx = pd.Index(["h", "i", "j", "k", "l", "m", "n"])

In [168]: cats = pd.Categorical(["a", "a", "a", "a", "a", "a", "a"],
.....:                     categories=["a", "b"])
.....:

In [169]: values = [1, 1, 1, 1, 1, 1, 1]

In [170]: df = pd.DataFrame({"cats": cats, "values": values}, index=idx)

In [171]: df.iloc[2:4, :] = [["b", 2], ["b", 2]]

In [172]: df
Out[172]:
   cats  values
h     a      1
i     a      1
j     b      2
k     b      2
l     a      1
m     a      1
n     a      1

In [173]: try:
.....:     df.iloc[2:4, :] = [["c", 3], ["c", 3]]
.....: except ValueError as e:
.....:     print("ValueError:", str(e))
.....:
ValueError: Cannot setitem on a Categorical with a new category, set the categories ↴
first
```

Setting values by assigning categorical data will also check that the *categories* match:

```
In [174]: df.loc["j":"k", "cats"] = pd.Categorical(["a", "a"], categories=["a", "b"])

In [175]: df
Out[175]:
   cats  values
h     a      1
i     a      1
j     a      2
k     a      2
l     a      1
m     a      1
n     a      1
```

(continues on next page)

(continued from previous page)

```
In [176]: try:
.....:     df.loc["j":"k", "cats"] = pd.Categorical(["b", "b"],
.....:                                                 categories=["a", "b", "c"])
.....: except ValueError as e:
.....:     print("ValueError:", str(e))
.....:
ValueError: Cannot set a Categorical with another, without identical categories
```

Assigning a Categorical to parts of a column of other types will use the values:

```
In [177]: df = pd.DataFrame({"a": [1, 1, 1, 1, 1], "b": ["a", "a", "a", "a", "a"]})

In [178]: df.loc[1:2, "a"] = pd.Categorical(["b", "b"], categories=["a", "b"])

In [179]: df.loc[2:3, "b"] = pd.Categorical(["b", "b"], categories=["a", "b"])

In [180]: df
Out[180]:
   a   b
0  1  a
1  b  a
2  b  b
3  1  b
4  1  a

In [181]: df.dtypes
Out[181]:
a    object
b    object
dtype: object
```

Merging / Concatenation

By default, combining Series or DataFrames which contain the same categories results in category dtype, otherwise results will depend on the dtype of the underlying categories. Merges that result in non-categorical dtypes will likely have higher memory usage. Use .astype or union_categoricals to ensure category results.

```
In [182]: from pandas.api.types import union_categoricals

# same categories
In [183]: s1 = pd.Series(['a', 'b'], dtype='category')

In [184]: s2 = pd.Series(['a', 'b', 'a'], dtype='category')

In [185]: pd.concat([s1, s2])
Out[185]:
0    a
1    b
0    a
1    b
2    a
dtype: category
Categories (2, object): [a, b]
```

(continues on next page)

(continued from previous page)

```
# different categories
In [186]: s3 = pd.Series(['b', 'c'], dtype='category')

In [187]: pd.concat([s1, s3])
Out[187]:
0    a
1    b
0    b
1    c
dtype: object

# Output dtype is inferred based on categories values
In [188]: int_cats = pd.Series([1, 2], dtype="category")

In [189]: float_cats = pd.Series([3.0, 4.0], dtype="category")

In [190]: pd.concat([int_cats, float_cats])
Out[190]:
0    1.0
1    2.0
0    3.0
1    4.0
dtype: float64

In [191]: pd.concat([s1, s3]).astype('category')
Out[191]:
0    a
1    b
0    b
1    c
dtype: category
Categories (3, object): [a, b, c]

In [192]: union_categoricals([s1.array, s3.array])
Out[192]:
[a, b, b, c]
Categories (3, object): [a, b, c]
```

The following table summarizes the results of merging Categoricals:

arg1	arg2	identical	result
category	category	True	category
category (object)	category (object)	False	object (dtype is inferred)
category (int)	category (float)	False	float (dtype is inferred)

See also the section on [merge dtypes](#) for notes about preserving merge dtypes and performance.

Unioning

If you want to combine categoricals that do not necessarily have the same categories, the `union_categoricals()` function will combine a list-like of categoricals. The new categories will be the union of the categories being combined.

```
In [193]: from pandas.api.types import union_categoricals

In [194]: a = pd.Categorical(["b", "c"])

In [195]: b = pd.Categorical(["a", "b"])

In [196]: union_categoricals([a, b])
Out[196]:
[b, c, a, b]
Categories (3, object): [b, c, a]
```

By default, the resulting categories will be ordered as they appear in the data. If you want the categories to be lexicographically sorted, use `sort_categories=True` argument.

```
In [197]: union_categoricals([a, b], sort_categories=True)
Out[197]:
[b, c, a, b]
Categories (3, object): [a, b, c]
```

`union_categoricals` also works with the “easy” case of combining two categoricals of the same categories and order information (e.g. what you could also append for).

```
In [198]: a = pd.Categorical(["a", "b"], ordered=True)

In [199]: b = pd.Categorical(["a", "b", "a"], ordered=True)

In [200]: union_categoricals([a, b])
Out[200]:
[a, b, a, b, a]
Categories (2, object): [a < b]
```

The below raises `TypeError` because the categories are ordered and not identical.

```
In [1]: a = pd.Categorical(["a", "b"], ordered=True)
In [2]: b = pd.Categorical(["a", "b", "c"], ordered=True)
In [3]: union_categoricals([a, b])
Out[3]:
TypeError: to union ordered Categoricals, all categories must be the same
```

Ordered categoricals with different categories or orderings can be combined by using the `ignore_ordered=True` argument.

```
In [201]: a = pd.Categorical(["a", "b", "c"], ordered=True)

In [202]: b = pd.Categorical(["c", "b", "a"], ordered=True)

In [203]: union_categoricals([a, b], ignore_order=True)
Out[203]:
[a, b, c, c, b, a]
Categories (3, object): [a, b, c]
```

`union_categoricals()` also works with a `CategoricalIndex`, or `Series` containing categorical data, but note that the resulting array will always be a plain `Categorical`:

```
In [204]: a = pd.Series(["b", "c"], dtype='category')

In [205]: b = pd.Series(["a", "b"], dtype='category')

In [206]: union_categoricals([a, b])
Out[206]:
[b, c, a, b]
Categories (3, object): [b, c, a]
```

Note: `union_categoricals` may recode the integer codes for categories when combining categoricals. This is likely what you want, but if you are relying on the exact numbering of the categories, be aware.

```
In [207]: c1 = pd.Categorical(["b", "c"])

In [208]: c2 = pd.Categorical(["a", "b"])

In [209]: c1
Out[209]:
[b, c]
Categories (2, object): [b, c]

# "b" is coded to 0
In [210]: c1.codes
Out[210]: array([0, 1], dtype=int8)

In [211]: c2
Out[211]:
[a, b]
Categories (2, object): [a, b]

# "b" is coded to 1
In [212]: c2.codes
Out[212]: array([0, 1], dtype=int8)

In [213]: c = union_categoricals([c1, c2])

In [214]: c
Out[214]:
[b, c, a, b]
Categories (3, object): [b, c, a]

# "b" is coded to 0 throughout, same as c1, different from c2
In [215]: c.codes
Out[215]: array([0, 1, 2, 0], dtype=int8)
```

3.8.9 Getting data in/out

You can write data that contains `category` dtypes to a HDFStore. See [here](#) for an example and caveats.

It is also possible to write data to and reading data from *Stata* format files. See [here](#) for an example and caveats.

Writing to a CSV file will convert the data, effectively removing any information about the categorical (categories and ordering). So if you read back the CSV file you have to convert the relevant columns back to `category` and assign the right categories and categories ordering.

```
In [216]: import io

In [217]: s = pd.Series(pd.Categorical(['a', 'b', 'b', 'a', 'a', 'd']))

# rename the categories
In [218]: s.cat.categories = ["very good", "good", "bad"]

# reorder the categories and add missing categories
In [219]: s = s.cat.set_categories(["very bad", "bad", "medium", "good", "very good"])

In [220]: df = pd.DataFrame({"cats": s, "vals": [1, 2, 3, 4, 5, 6]})

In [221]: csv = io.StringIO()

In [222]: df.to_csv(csv)

In [223]: df2 = pd.read_csv(io.StringIO(csv.getvalue()))

In [224]: df2.dtypes
Out[224]:
Unnamed: 0      int64
cats            object
vals            int64
dtype: object

In [225]: df2["cats"]
Out[225]:
0    very good
1        good
2        good
3    very good
4    very good
5        bad
Name: cats, dtype: object

# Redo the category
In [226]: df2["cats"] = df2["cats"].astype("category")

In [227]: df2["cats"].cat.set_categories(["very bad", "bad", "medium",
.....:                               "good", "very good"],
.....:                               inplace=True)
.....:

In [228]: df2.dtypes
Out[228]:
Unnamed: 0      int64
cats            category
vals            int64
```

(continues on next page)

(continued from previous page)

```
dtype: object

In [229]: df2["cats"]
Out[229]:
0    very good
1        good
2        good
3    very good
4    very good
5        bad
Name: cats, dtype: category
Categories (5, object): [very bad, bad, medium, good, very good]
```

The same holds for writing to a SQL database with `to_sql`.

3.8.10 Missing data

pandas primarily uses the value `np.nan` to represent missing data. It is by default not included in computations. See the [Missing Data section](#).

Missing values should **not** be included in the Categorical's categories, only in the values. Instead, it is understood that NaN is different, and is always a possibility. When working with the Categorical's codes, missing values will always have a code of -1.

```
In [230]: s = pd.Series(["a", "b", np.nan, "a"], dtype="category")

# only two categories
In [231]: s
Out[231]:
0    a
1    b
2    NaN
3    a
dtype: category
Categories (2, object): [a, b]

In [232]: s.cat.codes
Out[232]:
0    0
1    1
2   -1
3    0
dtype: int8
```

Methods for working with missing data, e.g. `isna()`, `fillna()`, `dropna()`, all work normally:

```
In [233]: s = pd.Series(["a", "b", np.nan], dtype="category")

In [234]: s
Out[234]:
0    a
1    b
2    NaN
dtype: category
Categories (2, object): [a, b]
```

(continues on next page)

(continued from previous page)

```
In [235]: pd.isna(s)
Out[235]:
0    False
1    False
2     True
dtype: bool

In [236]: s.fillna("a")
Out[236]:
0    a
1    b
2    a
dtype: category
Categories (2, object): [a, b]
```

3.8.11 Differences to R's `factor`

The following differences to R's factor functions can be observed:

- R's *levels* are named *categories*.
- R's *levels* are always of type string, while *categories* in pandas can be of any dtype.
- It's not possible to specify labels at creation time. Use `s.cat.rename_categories(new_labels)` afterwards.
- In contrast to R's *factor* function, using categorical data as the sole input to create a new categorical series will *not* remove unused categories but create a new categorical series which is equal to the passed in one!
- R allows for missing values to be included in its *levels* (pandas' *categories*). Pandas does not allow *NaN* categories, but missing values can still be in the *values*.

3.8.12 Gotchas

Memory usage

The memory usage of a Categorical is proportional to the number of categories plus the length of the data. In contrast, an `object` dtype is a constant times the length of the data.

```
In [237]: s = pd.Series(['foo', 'bar'] * 1000)

# object dtype
In [238]: s.nbytes
Out[238]: 16000

# category dtype
In [239]: s.astype('category').nbytes
Out[239]: 2016
```

Note: If the number of categories approaches the length of the data, the Categorical will use nearly the same or more memory than an equivalent `object` dtype representation.

```
In [240]: s = pd.Series(['foo%04d' % i for i in range(2000)])  
  
# object dtype  
In [241]: s nbytes  
Out[241]: 16000  
  
# category dtype  
In [242]: s.astype('category'). nbytes  
Out[242]: 20000
```

Categorical is not a numpy array

Currently, categorical data and the underlying Categorical is implemented as a Python object and not as a low-level NumPy array dtype. This leads to some problems.

NumPy itself doesn't know about the new *dtype*:

```
In [243]: try:  
.....:     np.dtype("category")  
.....: except TypeError as e:  
.....:     print("TypeError:", str(e))  
.....:  
TypeError: data type "category" not understood  
  
In [244]: dtype = pd.Categorical(["a"]). dtype  
  
In [245]: try:  
.....:     np.dtype(dtype)  
.....: except TypeError as e:  
.....:     print("TypeError:", str(e))  
.....:  
TypeError: data type not understood
```

Dtype comparisons work:

```
In [246]: dtype == np.str_  
Out[246]: False  
  
In [247]: np.str_ == dtype  
Out[247]: False
```

To check if a Series contains Categorical data, use `hasattr(s, 'cat')`:

```
In [248]: hasattr(pd.Series(['a']), 'category'), 'cat')  
Out[248]: True  
  
In [249]: hasattr(pd.Series(['a']), 'cat')  
Out[249]: False
```

Using NumPy functions on a Series of type `category` should not work as *Categoricals* are not numeric data (even in the case that `.categories` is numeric).

```
In [250]: s = pd.Series(pd.Categorical([1, 2, 3, 4]))  
  
In [251]: try:
```

(continues on next page)

(continued from previous page)

```

.....:     np.sum(s)
.....: except TypeError as e:
.....:     print("TypeError:", str(e))
.....:
TypeError: Categorical cannot perform the operation sum

```

Note: If such a function works, please file a bug at <https://github.com/pandas-dev/pandas>!

dtype in apply

Pandas currently does not preserve the dtype in apply functions: If you apply along rows you get a *Series* of object *dtype* (same as getting a row -> getting one element will return a basic type) and applying along columns will also convert to object. NaN values are unaffected. You can use `fillna` to handle missing values before applying a function.

```

In [252]: df = pd.DataFrame({"a": [1, 2, 3, 4],
.....:                     "b": ["a", "b", "c", "d"],
.....:                     "cats": pd.Categorical([1, 2, 3, 2])})
.....:

In [253]: df.apply(lambda row: type(row["cats"]), axis=1)
Out[253]:
0    <class 'int'>
1    <class 'int'>
2    <class 'int'>
3    <class 'int'>
dtype: object

In [254]: df.apply(lambda col: col.dtype, axis=0)
Out[254]:
a        int64
b        object
cats    category
dtype: object

```

Categorical index

`CategoricalIndex` is a type of index that is useful for supporting indexing with duplicates. This is a container around a `Categorical` and allows efficient indexing and storage of an index with a large number of duplicated elements. See the [advanced indexing docs](#) for a more detailed explanation.

Setting the index will create a `CategoricalIndex`:

```

In [255]: cats = pd.Categorical([1, 2, 3, 4], categories=[4, 2, 3, 1])

In [256]: strings = ["a", "b", "c", "d"]

In [257]: values = [4, 2, 3, 1]

In [258]: df = pd.DataFrame({"strings": strings, "values": values}, index=cats)

In [259]: df.index

```

(continues on next page)

(continued from previous page)

```
Out[259]: CategoricalIndex([1, 2, 3, 4], categories=[4, 2, 3, 1], ordered=False, dtype='category')  
  
# This now sorts by the categories order  
In [260]: df.sort_index()  
Out[260]:  
    strings  values  
4          d      1  
2          b      2  
3          c      3  
1          a      4
```

Side effects

Constructing a Series from a Categorical will not copy the input Categorical. This means that changes to the Series will in most cases change the original Categorical:

```
In [261]: cat = pd.Categorical([1, 2, 3, 10], categories=[1, 2, 3, 4, 10])  
  
In [262]: s = pd.Series(cat, name="cat")  
  
In [263]: cat  
Out[263]:  
[1, 2, 3, 10]  
Categories (5, int64): [1, 2, 3, 4, 10]  
  
In [264]: s.iloc[0:2] = 10  
  
In [265]: cat  
Out[265]:  
[10, 10, 3, 10]  
Categories (5, int64): [1, 2, 3, 4, 10]  
  
In [266]: df = pd.DataFrame(s)  
  
In [267]: df["cat"].cat.categories = [1, 2, 3, 4, 5]  
  
In [268]: cat  
Out[268]:  
[5, 5, 3, 5]  
Categories (5, int64): [1, 2, 3, 4, 5]
```

Use `copy=True` to prevent such a behaviour or simply don't reuse Categoricals:

```
In [269]: cat = pd.Categorical([1, 2, 3, 10], categories=[1, 2, 3, 4, 10])  
  
In [270]: s = pd.Series(cat, name="cat", copy=True)  
  
In [271]: cat  
Out[271]:  
[1, 2, 3, 10]  
Categories (5, int64): [1, 2, 3, 4, 10]  
  
In [272]: s.iloc[0:2] = 10
```

(continues on next page)

(continued from previous page)

```
In [273]: cat
Out[273]:
[1, 2, 3, 10]
Categories (5, int64): [1, 2, 3, 4, 10]
```

Note: This also happens in some cases when you supply a NumPy array instead of a Categorical: using an int array (e.g. `np.array([1, 2, 3, 4])`) will exhibit the same behavior, while using a string array (e.g. `np.array(["a", "b", "c", "a"])`) will not.

```
{{ header }}
```

3.9 Nullable integer data type

New in version 0.24.0.

Note: IntegerArray is currently experimental. Its API or implementation may change without warning.

Changed in version 1.0.0: Now uses `pandas.NA` as the missing value rather than `numpy.nan`.

In [Missing Data](#), we saw that pandas primarily uses `NaN` to represent missing data. Because `NaN` is a float, this forces an array of integers with any missing values to become floating point. In some cases, this may not matter much. But if your integer column is, say, an identifier, casting to float can be problematic. Some integers cannot even be represented as floating point numbers.

3.9.1 Construction

Pandas can represent integer data with possibly missing values using `arrays.IntegerArray`. This is an *extension types* implemented within pandas.

```
In [1]: arr = pd.array([1, 2, None], dtype=pd.Int64Dtype())
In [2]: arr
Out[2]:
<IntegerArray>
[1, 2, <NA>]
Length: 3, dtype: Int64
```

Or the string alias "`Int64`" (note the capital "`I`", to differentiate from NumPy's '`int64`' dtype:

```
In [3]: pd.array([1, 2, np.nan], dtype="Int64")
Out[3]:
<IntegerArray>
[1, 2, <NA>]
Length: 3, dtype: Int64
```

All NA-like values are replaced with `pandas.NA`.

```
In [4]: pd.array([1, 2, np.nan, None, pd.NA], dtype="Int64")
Out[4]:
```

(continues on next page)

(continued from previous page)

```
<IntegerArray>
[1, 2, <NA>, <NA>, <NA>]
Length: 5, dtype: Int64
```

This array can be stored in a `DataFrame` or `Series` like any NumPy array.

```
In [5]: pd.Series(arr)
Out[5]:
0      1
1      2
2    <NA>
dtype: Int64
```

You can also pass the list-like object to the `Series` constructor with the `dtype`.

Warning: Currently `pandas.array()` and `pandas.Series()` use different rules for `dtype` inference. `pandas.array()` will infer a nullable-integer `dtype`

```
In [6]: pd.array([1, None])
Out[6]:
<IntegerArray>
[1, <NA>]
Length: 2, dtype: Int64

In [7]: pd.array([1, 2])
Out[7]:
<IntegerArray>
[1, 2]
Length: 2, dtype: Int64
```

For backwards-compatibility, `Series` infers these as either integer or float `dtype`

```
In [8]: pd.Series([1, None])
Out[8]:
0    1.0
1    NaN
dtype: float64

In [9]: pd.Series([1, 2])
Out[9]:
0    1
1    2
dtype: int64
```

We recommend explicitly providing the `dtype` to avoid confusion.

```
In [10]: pd.array([1, None], dtype="Int64")
Out[10]:
<IntegerArray>
[1, <NA>]
Length: 2, dtype: Int64

In [11]: pd.Series([1, None], dtype="Int64")
Out[11]:
0    1
1    <NA>
dtype: Int64
```

In the future, we may provide an option for `Series` to infer a nullable-integer dtype.

3.9.2 Operations

Operations involving an integer array will behave similar to NumPy arrays. Missing values will be propagated, and the data will be coerced to another dtype if needed.

```
In [12]: s = pd.Series([1, 2, None], dtype="Int64")

# arithmetic
In [13]: s + 1
Out[13]:
0      2
1      3
2    <NA>
dtype: Int64

# comparison
In [14]: s == 1
Out[14]:
0    True
1   False
2    <NA>
dtype: boolean

# indexing
In [15]: s.iloc[1:3]
Out[15]:
1      2
2    <NA>
dtype: Int64

# operate with other dtypes
In [16]: s + s.iloc[1:3].astype('Int8')
Out[16]:
0    <NA>
1      4
2    <NA>
dtype: Int64

# coerce when needed
In [17]: s + 0.01
Out[17]:
0    1.01
1    2.01
2     NaN
dtype: float64
```

These dtypes can operate as part of DataFrame.

```
In [18]: df = pd.DataFrame({'A': s, 'B': [1, 1, 3], 'C': list('aab')})

In [19]: df
Out[19]:
   A   B   C
0  1  1  a
1  2  1  a
2  Na  3  b
```

(continues on next page)

(continued from previous page)

```
0      1  1   a
1      2  1   a
2  <NA>  3   b
```

In [20]: df.dtypes

Out[20]:

```
A    Int64
B    int64
C    object
dtype: object
```

These dtypes can be merged & reshaped & casted.

In [21]: pd.concat([df[['A']], df[['B', 'C']]], axis=1).dtypes

Out[21]:

```
A    Int64
B    int64
C    object
dtype: object
```

In [22]: df['A'].astype(float)

Out[22]:

```
0    1.0
1    2.0
2    NaN
Name: A, dtype: float64
```

Reduction and groupby operations such as ‘sum’ work as well.

In [23]: df.sum()

Out[23]:

```
A    3
B    5
C    aab
dtype: object
```

In [24]: df.groupby('B').A.sum()

Out[24]:

```
B
1    3
3    0
Name: A, dtype: Int64
```

3.9.3 Scalar NA Value

`arrays.IntegerArray` uses `pandas.NA` as its scalar missing value. Slicing a single element that’s missing will return `pandas.NA`

In [25]: a = pd.array([1, None], dtype="Int64")

In [26]: a[1]

Out[26]: <NA>

3.10 Nullable Boolean Data Type

New in version 1.0.0.

3.10.1 Indexing with NA values

pandas does not allow indexing with NA values. Attempting to do so will raise a `ValueError`.

```
In [1]: s = pd.Series([1, 2, 3])

In [2]: mask = pd.array([True, False, pd.NA], dtype="boolean")

In [3]: s[mask]
-----
ValueError                                                 Traceback (most recent call last)
<ipython-input-3-b9628bf46992> in <module>
----> 1 s[mask]

/pandas/pandas/core/series.py in __getitem__(self, key)
    905         key = list(key)
    906
--> 907     if com.is_bool_indexer(key):
    908         key = check_bool_indexer(self.index, key)
    909

/pandas/pandas/core/common.py in is_bool_indexer(key)
    142         if is_extension_array_dtype(key.dtype):
    143             if np.any(key.isna()):
--> 144                 raise ValueError(na_msg)
    145             return True
    146     elif isinstance(key, list):
```

ValueError: cannot mask with array containing NA / NaN values

The missing values will need to be explicitly filled with `True` or `False` prior to using the array as a mask.

```
In [4]: s[mask.fillna(False)]
Out[4]:
0    1
dtype: int64
```

3.10.2 Kleene Logical Operations

`arrays.BooleanArray` implements Kleene Logic (sometimes called three-value logic) for logical operations like `&` (and), `|` (or) and `^` (exclusive-or).

This table demonstrates the results for every combination. These operations are symmetrical, so flipping the left- and right-hand side makes no difference in the result.

Expression	Result
True & True	True
True & False	False
True & NA	NA
False & False	False
False & NA	False
NA & NA	NA
True True	True
True False	True
True NA	True
False False	False
False NA	NA
NA NA	NA
True ^ True	False
True ^ False	True
True ^ NA	NA
False ^ False	False
False ^ NA	NA
NA ^ NA	NA

When an NA is present in an operation, the output value is NA only if the result cannot be determined solely based on the other input. For example, True | NA is True, because both True | True and True | False are True. In that case, we don't actually need to consider the value of the NA.

On the other hand, True & NA is NA. The result depends on whether the NA really is True or False, since True & True is True, but True & False is False, so we can't determine the output.

This differs from how np.nan behaves in logical operations. Pandas treated np.nan as *always false in the output*.

In or

```
In [5]: pd.Series([True, False, np.nan], dtype="object") | True
Out[5]:
0    True
1    True
2    False
dtype: bool

In [6]: pd.Series([True, False, np.nan], dtype="boolean") | True
Out[6]:
0    True
1    True
2    True
dtype: boolean
```

In and

```
In [7]: pd.Series([True, False, np.nan], dtype="object") & True
Out[7]:
0    True
1    False
2    False
dtype: bool

In [8]: pd.Series([True, False, np.nan], dtype="boolean") & True
```

(continues on next page)

(continued from previous page)

```
Out[8]:  
0      True  
1     False  
2    <NA>  
dtype: boolean
```

```
{{ header }}
```

3.11 Visualization

We use the standard convention for referencing the matplotlib API:

```
In [1]: import matplotlib.pyplot as plt
```

```
In [2]: plt.close('all')
```

We provide the basics in pandas to easily create decent looking plots. See the ecosystem section for visualization libraries that go beyond the basics documented here.

Note: All calls to np.random are seeded with 123456.

3.11.1 Basic plotting: plot

We will demonstrate the basics, see the [cookbook](#) for some advanced strategies.

The plot method on Series and DataFrame is just a simple wrapper around plt.plot():

```
In [3]: ts = pd.Series(np.random.randn(1000),  
...:                     index=pd.date_range('1/1/2000', periods=1000))  
...:  
  
In [4]: ts = ts.cumsum()  
  
In [5]: ts.plot()  
Out[5]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d64720a90>
```

If the index consists of dates, it calls `gcf().autofmt_xdate()` to try to format the x-axis nicely as per above.

On DataFrame, `plot()` is a convenience to plot all of the columns with labels:

```
In [6]: df = pd.DataFrame(np.random.randn(1000, 4),
...                      index=ts.index, columns=list('ABCD'))
...
In [7]: df = df.cumsum()
In [8]: plt.figure();
In [9]: df.plot();
```

You can plot one column versus another using the `x` and `y` keywords in `plot()`:

```
In [10]: df3 = pd.DataFrame(np.random.randn(1000, 2), columns=['B', 'C']).cumsum()  
  
In [11]: df3['A'] = pd.Series(list(range(len(df))))  
  
In [12]: df3.plot(x='A', y='B')  
Out[12]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d65f6b8d0>
```

Note: For more formatting and styling options, see [formatting](#) below.

3.11.2 Other plots

Plotting methods allow for a handful of plot styles other than the default line plot. These methods can be provided as the `kind` keyword argument to `plot()`, and include:

- ‘`bar`’ or ‘`barh`’ for bar plots
- ‘`hist`’ for histogram
- ‘`box`’ for boxplot
- ‘`kde`’ or ‘`density`’ for density plots
- ‘`area`’ for area plots
- ‘`scatter`’ for scatter plots
- ‘`hexbin`’ for hexagonal bin plots
- ‘`pie`’ for pie plots

For example, a bar plot can be created the following way:

```
In [13]: plt.figure();
```

```
In [14]: df.iloc[5].plot(kind='bar');
```

You can also create these other plots using the methods `DataFrame.plot.<kind>` instead of providing the `kind` keyword argument. This makes it easier to discover plot methods and the specific arguments they use:

```
In [15]: df = pd.DataFrame()
```

```
In [16]: df.plot.<TAB> # noqa: E225, E999
df.plot.area      df.plot.barsh     df.plot.density   df.plot.hist      df.plot.line
df.plot.scatter
df.plot.bar       df.plot.box      df.plot.hexbin   df.plot.kde       df.plot.pie
```

In addition to these `kind`s, there are the `DataFrame.hist()`, and `DataFrame.boxplot()` methods, which use a separate interface.

Finally, there are several *plotting functions* in `pandas.plotting` that take a `Series` or `DataFrame` as an argument. These include:

- *Scatter Matrix*
- *Andrews Curves*
- *Parallel Coordinates*
- *Lag Plot*

- Autocorrelation Plot
- Bootstrap Plot
- RadViz

Plots may also be adorned with *errorbars* or *tables*.

Bar plots

For labeled, non-time series data, you may wish to produce a bar plot:

```
In [17]: plt.figure();  
  
In [18]: df.iloc[5].plot.bar()  
Out[18]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d64cff3d0>  
  
In [19]: plt.axhline(0, color='k');
```

Calling a DataFrame's `plot.bar()` method produces a multiple bar plot:

```
In [20]: df2 = pd.DataFrame(np.random.rand(10, 4), columns=['a', 'b', 'c', 'd'])  
  
In [21]: df2.plot.bar();
```

To produce a stacked bar plot, pass `stacked=True`:

```
In [22]: df2.plot.bar(stacked=True);
```

To get horizontal bar plots, use the `barh` method:

```
In [23]: df2.plot.barh(stacked=True);
```

Histograms

Histograms can be drawn by using the `DataFrame.plot.hist()` and `Series.plot.hist()` methods.

```
In [24]: df4 = pd.DataFrame({'a': np.random.randn(1000) + 1, 'b': np.random.
    ↪randn(1000),
    ....:
    ....:                               'c': np.random.randn(1000) - 1}, columns=['a', 'b', 'c'])

In [25]: plt.figure();

In [26]: df4.plot.hist(alpha=0.5)
Out[26]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6da63b18d0>
```

A histogram can be stacked using `stacked=True`. Bin size can be changed using the `bins` keyword.

```
In [27]: plt.figure();
```

```
In [28]: df4.plot.hist(stacked=True, bins=20)
```

```
Out[28]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d78496610>
```

You can pass other keywords supported by matplotlib hist. For example, horizontal and cumulative histograms can be drawn by `orientation='horizontal'` and `cumulative=True`.

```
In [29]: plt.figure();
```

```
In [30]: df4['a'].plot.hist(orientation='horizontal', cumulative=True)
Out[30]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d67597c90>
```

See the `hist` method and the [matplotlib hist documentation](#) for more.

The existing interface `DataFrame.hist` to plot histogram still can be used.

```
In [31]: plt.figure();

In [32]: df['A'].diff().hist()
Out[32]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d68e8b550>
```

DataFrame.hist() plots the histograms of the columns on multiple subplots:

```
In [33]: plt.figure()
Out[33]: <Figure size 640x480 with 0 Axes>

In [34]: df.diff().hist(color='k', alpha=0.5, bins=50)
Out[34]:
array([[<matplotlib.axes._subplots.AxesSubplot object at 0x7f6d65c63750>,
       <matplotlib.axes._subplots.AxesSubplot object at 0x7f6d65d63790>],
      [<matplotlib.axes._subplots.AxesSubplot object at 0x7f6d68ec73d0>,
       <matplotlib.axes._subplots.AxesSubplot object at 0x7f6da5ef3450>]],
     dtype=object)
```

The `by` keyword can be specified to plot grouped histograms:

```
In [35]: data = pd.Series(np.random.randn(1000))
```

```
In [36]: data.hist(by=np.random.randint(0, 4, 1000), figsize=(6, 4))
```

```
Out[36]:
```

```
array([[<matplotlib.axes._subplots.AxesSubplot object at 0x7f6d65c63a10>,
       <matplotlib.axes._subplots.AxesSubplot object at 0x7f6d6512db90>],
      [<matplotlib.axes._subplots.AxesSubplot object at 0x7f6d6510d7d0>,
       <matplotlib.axes._subplots.AxesSubplot object at 0x7f6d652cf4d0>]],
     dtype=object)
```

Box plots

Boxplot can be drawn calling `Series.plot.box()` and `DataFrame.plot.box()`, or `DataFrame.boxplot()` to visualize the distribution of values within each column.

For instance, here is a boxplot representing five trials of 10 observations of a uniform random variable on [0,1).

```
In [37]: df = pd.DataFrame(np.random.rand(10, 5), columns=['A', 'B', 'C', 'D', 'E'])

In [38]: df.plot.box()
Out[38]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d658644d0>
```

Boxplot can be colorized by passing `color` keyword. You can pass a dict whose keys are `boxes`, `whiskers`, `medians` and `caps`. If some keys are missing in the dict, default colors are used for the corresponding artists. Also, boxplot has `sym` keyword to specify fliers style.

When you pass other type of arguments via `color` keyword, it will be directly passed to matplotlib for all the boxes, whiskers, medians and caps colorization.

The colors are applied to every boxes to be drawn. If you want more complicated colorization, you can get each drawn artists by passing `return_type`.

```
In [39]: color = {'boxes': 'DarkGreen', 'whiskers': 'DarkOrange',
....:                 'medians': 'DarkBlue', 'caps': 'Gray'}
....:

In [40]: df.plot.box(color=color, sym='r+')
Out[40]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d66684f90>
```

Also, you can pass other keywords supported by matplotlib `boxplot`. For example, horizontal and custom-positioned boxplot can be drawn by `vert=False` and `positions` keywords.

```
In [41]: df.plot.box(vert=False, positions=[1, 4, 5, 6, 8])
Out[41]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d68c4b310>
```

See the `boxplot` method and the matplotlib `boxplot` documentation for more.

The existing interface `DataFrame.boxplot` to plot boxplot still can be used.

```
In [42]: df = pd.DataFrame(np.random.rand(10, 5))

In [43]: plt.figure();

In [44]: bp = df.boxplot()
```

You can create a stratified boxplot using the `by` keyword argument to create groupings. For instance,

```
In [45]: df = pd.DataFrame(np.random.rand(10, 2), columns=['Col1', 'Col2'])

In [46]: df['X'] = pd.Series(['A', 'A', 'A', 'A', 'A', 'B', 'B', 'B', 'B', 'B'])

In [47]: plt.figure();

In [48]: bp = df.boxplot(by='X')
```

You can also pass a subset of columns to plot, as well as group by multiple columns:

```
In [49]: df = pd.DataFrame(np.random.rand(10, 3), columns=['Col1', 'Col2', 'Col3'])

In [50]: df['X'] = pd.Series(['A', 'A', 'A', 'A', 'A', 'B', 'B', 'B', 'B', 'B'])

In [51]: df['Y'] = pd.Series(['A', 'B', 'A', 'B', 'A', 'B', 'A', 'B', 'A', 'B'])

In [52]: plt.figure();

In [53]: bp = df.boxplot(column=['Col1', 'Col2'], by=['X', 'Y'])
```

In boxplot, the return type can be controlled by the `return_type`, keyword. The valid choices are { "axes", "dict", "both", None}. Faceting, created by `DataFrame.boxplot` with the `by` keyword, will affect the output type as well:

<code>return_type=</code>	Faceted	Output type
None	No	axes
None	Yes	2-D ndarray of axes
'axes'	No	axes
'axes'	Yes	Series of axes
'dict'	No	dict of artists
'dict'	Yes	Series of dicts of artists
'both'	No	namedtuple
'both'	Yes	Series of namedtuples

`Groupby.boxplot` always returns a Series of `return_type`.

```
In [54]: np.random.seed(1234)

In [55]: df_box = pd.DataFrame(np.random.randn(50, 2))

In [56]: df_box['g'] = np.random.choice(['A', 'B'], size=50)

In [57]: df_box.loc[df_box['g'] == 'B', 1] += 3
```

(continues on next page)

(continued from previous page)

```
In [58]: bp = df_box.boxplot(by='g')
```

The subplots above are split by the numeric columns first, then the value of the `g` column. Below the subplots are first split by the value of `g`, then by the numeric columns.

```
In [59]: bp = df_box.groupby('g').boxplot()
```

Area plot

You can create area plots with `Series.plot.area()` and `DataFrame.plot.area()`. Area plots are stacked by default. To produce stacked area plot, each column must be either all positive or all negative values.

When input data contains `NaN`, it will be automatically filled by 0. If you want to drop or fill by different values, use `dataframe.dropna()` or `dataframe.fillna()` before calling `plot`.

```
In [60]: df = pd.DataFrame(np.random.rand(10, 4), columns=['a', 'b', 'c', 'd'])  
In [61]: df.plot.area();
```

To produce an unstacked plot, pass `stacked=False`. Alpha value is set to 0.5 unless otherwise specified:

```
In [62]: df.plot.area(stacked=False);
```

Scatter plot

Scatter plot can be drawn by using the `DataFrame.plot.scatter()` method. Scatter plot requires numeric columns for the x and y axes. These can be specified by the `x` and `y` keywords.

```
In [63]: df = pd.DataFrame(np.random.rand(50, 4), columns=['a', 'b', 'c', 'd'])
```

```
In [64]: df.plot.scatter(x='a', y='b');
```

To plot multiple column groups in a single axes, repeat `plot` method specifying target `ax`. It is recommended to specify `color` and `label` keywords to distinguish each groups.

```
In [65]: ax = df.plot.scatter(x='a', y='b', color='DarkBlue', label='Group 1');
```

```
In [66]: df.plot.scatter(x='c', y='d', color='DarkGreen', label='Group 2', ax=ax);
```

The keyword `c` may be given as the name of a column to provide colors for each point:

```
In [67]: df.plot.scatter(x='a', y='b', c='c', s=50);
```

You can pass other keywords supported by matplotlib `scatter`. The example below shows a bubble chart using a column of the DataFrame as the bubble size.

```
In [68]: df.plot.scatter(x='a', y='b', s=df['c'] * 200);
```

See the `scatter` method and the matplotlib scatter documentation for more.

Hexagonal bin plot

You can create hexagonal bin plots with `DataFrame.plot.hexbin()`. Hexbin plots can be a useful alternative to scatter plots if your data are too dense to plot each point individually.

```
In [69]: df = pd.DataFrame(np.random.randn(1000, 2), columns=['a', 'b'])

In [70]: df['b'] = df['b'] + np.arange(1000)

In [71]: df.plot.hexbin(x='a', y='b', gridsize=25)
Out[71]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d648f8150>
```

A useful keyword argument is `gridsize`; it controls the number of hexagons in the x-direction, and defaults to 100. A larger `gridsize` means more, smaller bins.

By default, a histogram of the counts around each (`x`, `y`) point is computed. You can specify alternative aggregations by passing values to the `C` and `reduce_C_function` arguments. `C` specifies the value at each (`x`, `y`) point and `reduce_C_function` is a function of one argument that reduces all the values in a bin to a single number (e.g. mean, max, sum, std). In this example the positions are given by columns `a` and `b`, while the value is given by column `z`. The bins are aggregated with NumPy's `max` function.

```
In [72]: df = pd.DataFrame(np.random.randn(1000, 2), columns=['a', 'b'])

In [73]: df['b'] = df['b'] = df['b'] + np.arange(1000)

In [74]: df['z'] = np.random.uniform(0, 3, 1000)

In [75]: df.plot.hexbin(x='a', y='b', C='z', reduce_C_function=np.max, gridsize=25)
Out[75]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d64a4f610>
```

See the `hexbin` method and the [matplotlib hexbin](#) documentation for more.

Pie plot

You can create a pie plot with `DataFrame.plot.pie()` or `Series.plot.pie()`. If your data includes any `NaN`, they will be automatically filled with 0. A `ValueError` will be raised if there are any negative values in your data.

```
In [76]: series = pd.Series(3 * np.random.rand(4),
....:                         index=['a', 'b', 'c', 'd'], name='series')
....:

In [77]: series.plot.pie(figsize=(6, 6))
Out[77]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d65496250>
```

For pie plots it's best to use square figures, i.e. a figure aspect ratio 1. You can create the figure with equal width and height, or force the aspect ratio to be equal after plotting by calling `ax.set_aspect('equal')` on the returned axes object.

Note that pie plot with `DataFrame` requires that you either specify a target column by the `y` argument or `subplots=True`. When `y` is specified, pie plot of selected column will be drawn. If `subplots=True` is specified, pie plots for each column are drawn as subplots. A legend will be drawn in each pie plots by default; specify `legend=False` to hide it.

```
In [78]: df = pd.DataFrame(3 * np.random.rand(4, 2),
.....:                     index=['a', 'b', 'c', 'd'], columns=['x', 'y'])

In [79]: df.plot.pie(subplots=True, figsize=(8, 4))
Out[79]: array([<matplotlib.axes._subplots.AxesSubplot object at 0x7f6d651d2450>,
```

(continues on next page)

(continued from previous page)

```
<matplotlib.axes._subplots.AxesSubplot object at 0x7f6d66c30990>,
dtype=object)
```

You can use the `labels` and `colors` keywords to specify the labels and colors of each wedge.

Warning: Most pandas plots use the `label` and `color` arguments (note the lack of “s” on those). To be consistent with `matplotlib.pyplot.pie()` you must use `labels` and `colors`.

If you want to hide wedge labels, specify `labels=None`. If `fontsize` is specified, the value will be applied to wedge labels. Also, other keywords supported by `matplotlib.pyplot.pie()` can be used.

```
In [80]: series.plot.pie(labels=['AA', 'BB', 'CC', 'DD'], colors=['r', 'g', 'b', 'c'],
.....:                     autopct='%.2f', fontsize=20, figsize=(6, 6))
.....:
Out[80]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d66c5a250>
```

If you pass values whose sum total is less than 1.0, matplotlib draws a semicircle.

```
In [81]: series = pd.Series([0.1] * 4, index=['a', 'b', 'c', 'd'], name='series2')

In [82]: series.plot.pie(figsize=(6, 6))
Out[82]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d672b4a90>
```

See the [matplotlib pie documentation](#) for more.

3.11.3 Plotting with missing data

Pandas tries to be pragmatic about plotting DataFrames or Series that contain missing data. Missing values are dropped, left out, or filled depending on the plot type.

Plot Type	NaN Handling
Line	Leave gaps at NaNs
Line (stacked)	Fill 0's
Bar	Fill 0's
Scatter	Drop NaNs
Histogram	Drop NaNs (column-wise)
Box	Drop NaNs (column-wise)
Area	Fill 0's
KDE	Drop NaNs (column-wise)
Hexbin	Drop NaNs
Pie	Fill 0's

If any of these defaults are not what you want, or if you want to be explicit about how missing values are handled, consider using `fillna()` or `dropna()` before plotting.

3.11.4 Plotting Tools

These functions can be imported from `pandas.plotting` and take a `Series` or `DataFrame` as an argument.

Scatter matrix plot

You can create a scatter plot matrix using the `scatter_matrix` method in `pandas.plotting`:

```
In [83]: from pandas.plotting import scatter_matrix

In [84]: df = pd.DataFrame(np.random.randn(1000, 4), columns=['a', 'b', 'c', 'd'])

In [85]: scatter_matrix(df, alpha=0.2, figsize=(6, 6), diagonal='kde')
Out[85]: array([[<matplotlib.axes._subplots.AxesSubplot object at 0x7f6d4a5609d0>,
   <matplotlib.axes._subplots.AxesSubplot object at 0x7f6d657dca50>,
   <matplotlib.axes._subplots.AxesSubplot object at 0x7f6d6441add0>,
   <matplotlib.axes._subplots.AxesSubplot object at 0x7f6d66ae8a90>],
  [<matplotlib.axes._subplots.AxesSubplot object at 0x7f6d652f1e10>,
   <matplotlib.axes._subplots.AxesSubplot object at 0x7f6d653d4ad0>,
   <matplotlib.axes._subplots.AxesSubplot object at 0x7f6d65d5df50>,
   <matplotlib.axes._subplots.AxesSubplot object at 0x7f6d6724fb10>],
  [<matplotlib.axes._subplots.AxesSubplot object at 0x7f6d67241690>,
   <matplotlib.axes._subplots.AxesSubplot object at 0x7f6d66657090>,
   <matplotlib.axes._subplots.AxesSubplot object at 0x7f6d6dd99e90>,
   <matplotlib.axes._subplots.AxesSubplot object at 0x7f6d645edc90>],
  [<matplotlib.axes._subplots.AxesSubplot object at 0x7f6d66d21350>,
   <matplotlib.axes._subplots.AxesSubplot object at 0x7f6d6676d450>,
   <matplotlib.axes._subplots.AxesSubplot object at 0x7f6d64c73650>,
   <matplotlib.axes._subplots.AxesSubplot object at 0x7f6d661a5890>]],  
dtype=object)
```

Density plot

You can create density plots using the `Series.plot.kde()` and `DataFrame.plot.kde()` methods.

```
In [86]: ser = pd.Series(np.random.randn(1000))
```

```
In [87]: ser.plot.kde()
```

```
Out[87]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6da5768590>
```

Andrews curves

Andrews curves allow one to plot multivariate data as a large number of curves that are created using the attributes of samples as coefficients for Fourier series, see the [Wikipedia entry](#) for more information. By coloring these curves differently for each class it is possible to visualize data clustering. Curves belonging to samples of the same class will usually be closer together and form larger structures.

Note: The “Iris” dataset is available [here](#).

```
In [88]: from pandas.plotting import andrews_curves  
  
In [89]: data = pd.read_csv('data/iris.data')  
  
In [90]: plt.figure()  
Out[90]: <Figure size 640x480 with 0 Axes>  
  
In [91]: andrews_curves(data, 'Name')  
Out[91]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d66e55350>
```

Parallel coordinates

Parallel coordinates is a plotting technique for plotting multivariate data, see the [Wikipedia entry](#) for an introduction. Parallel coordinates allows one to see clusters in data and to estimate other statistics visually. Using parallel coordinates points are represented as connected line segments. Each vertical line represents one attribute. One set of connected line segments represents one data point. Points that tend to cluster will appear closer together.

```
In [92]: from pandas.plotting import parallel_coordinates  
  
In [93]: data = pd.read_csv('data/iris.data')  
  
In [94]: plt.figure()  
Out[94]: <Figure size 640x480 with 0 Axes>  
  
In [95]: parallel_coordinates(data, 'Name')  
Out[95]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d66e54410>
```

Lag plot

Lag plots are used to check if a data set or time series is random. Random data should not exhibit any structure in the lag plot. Non-random structure implies that the underlying data are not random. The `lag` argument may be passed, and when `lag=1` the plot is essentially `data[:-1]` vs. `data[1:]`.

```
In [96]: from pandas.plotting import lag_plot

In [97]: plt.figure()
Out[97]: <Figure size 640x480 with 0 Axes>

In [98]: spacing = np.linspace(-99 * np.pi, 99 * np.pi, num=1000)

In [99]: data = pd.Series(0.1 * np.random.rand(1000) + 0.9 * np.sin(spacing))

In [100]: lag_plot(data)
Out[100]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d661db150>
```

Autocorrelation plot

Autocorrelation plots are often used for checking randomness in time series. This is done by computing autocorrelations for data values at varying time lags. If time series is random, such autocorrelations should be near zero for any and all time-lag separations. If time series is non-random then one or more of the autocorrelations will be significantly non-zero. The horizontal lines displayed in the plot correspond to 95% and 99% confidence bands. The dashed line is 99% confidence band. See the [Wikipedia entry](#) for more about autocorrelation plots.

```
In [101]: from pandas.plotting import autocorrelation_plot
In [102]: plt.figure()
Out[102]: <Figure size 640x480 with 0 Axes>
In [103]: spacing = np.linspace(-9 * np.pi, 9 * np.pi, num=1000)
In [104]: data = pd.Series(0.7 * np.random.rand(1000) + 0.3 * np.sin(spacing))
In [105]: autocorrelation_plot(data)
Out[105]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d65fe11d0>
```

Bootstrap plot

Bootstrap plots are used to visually assess the uncertainty of a statistic, such as mean, median, midrange, etc. A random subset of a specified size is selected from a data set, the statistic in question is computed for this subset and the process is repeated a specified number of times. Resulting plots and histograms are what constitutes the bootstrap plot.

```
In [106]: from pandas.plotting import bootstrap_plot  
  
In [107]: data = pd.Series(np.random.rand(1000))  
  
In [108]: bootstrap_plot(data, size=50, samples=500, color='grey')  
Out[108]: <Figure size 640x480 with 6 Axes>
```

RadViz

RadViz is a way of visualizing multi-variate data. It is based on a simple spring tension minimization algorithm. Basically you set up a bunch of points in a plane. In our case they are equally spaced on a unit circle. Each point represents a single attribute. You then pretend that each sample in the data set is attached to each of these points by a spring, the stiffness of which is proportional to the numerical value of that attribute (they are normalized to unit interval). The point in the plane, where our sample settles to (where the forces acting on our sample are at an equilibrium) is where a dot representing our sample will be drawn. Depending on which class that sample belongs it will be colored differently. See the R package [Radviz](#) for more information.

Note: The “Iris” dataset is available [here](#).

```
In [109]: from pandas.plotting import radviz
In [110]: data = pd.read_csv('data/iris.data')
In [111]: plt.figure()
Out[111]: <Figure size 640x480 with 0 Axes>
In [112]: radviz(data, 'Name')
Out[112]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d6595bcd0>
```

3.11.5 Plot Formatting

Setting the plot style

From version 1.5 and up, matplotlib offers a range of pre-configured plotting styles. Setting the style can be used to easily give plots the general look that you want. Setting the style is as easy as calling `matplotlib.style.use(my_plot_style)` before creating your plot. For example you could write `matplotlib.style.use('ggplot')` for ggplot-style plots.

You can see the various available style names at `matplotlib.style.available` and it's very easy to try them out.

General plot style arguments

Most plotting methods have a set of keyword arguments that control the layout and formatting of the returned plot:

```
In [113]: plt.figure();  
In [114]: ts.plot(style='k--', label='Series');
```

For each kind of plot (e.g. *line*, *bar*, *scatter*) any additional arguments keywords are passed along to the corresponding matplotlib function (`ax.plot()`, `ax.bar()`, `ax.scatter()`). These can be used to control additional styling, beyond what pandas provides.

Controlling the legend

You may set the `legend` argument to `False` to hide the legend, which is shown by default.

```
In [115]: df = pd.DataFrame(np.random.randn(1000, 4),
.....:                               index=ts.index, columns=list('ABCD'))
.....:

In [116]: df = df.cumsum()

In [117]: df.plot(legend=False)
Out[117]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d6713a6d0>
```

Scales

You may pass `logy` to get a log-scale Y axis.

```
In [118]: ts = pd.Series(np.random.randn(1000),
.....:                     index=pd.date_range('1/1/2000', periods=1000))
.....:

In [119]: ts = np.exp(ts.cumsum())

In [120]: ts.plot(logy=True)
Out[120]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d660b7410>
```

See also the `logx` and `loglog` keyword arguments.

Plotting on a secondary y-axis

To plot data on a secondary y-axis, use the `secondary_y` keyword:

```
In [121]: df['A'].plot()
Out[121]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d66995f50>

In [122]: df['B'].plot(secondary_y=True, style='g')
Out[122]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d669a9e10>
```

To plot some columns in a DataFrame, give the column names to the `secondary_y` keyword:

```
In [123]: plt.figure()
Out[123]: <Figure size 640x480 with 0 Axes>

In [124]: ax = df.plot(secondary_y=['A', 'B'])

In [125]: ax.set_ylabel('CD scale')
Out[125]: Text(0, 0.5, 'CD scale')

In [126]: ax.right_ax.set_ylabel('AB scale')
Out[126]: Text(0, 0.5, 'AB scale')
```

Note that the columns plotted on the secondary y-axis is automatically marked with “(right)” in the legend. To turn off the automatic marking, use the `mark_right=False` keyword:

```
In [127]: plt.figure()
Out[127]: <Figure size 640x480 with 0 Axes>

In [128]: df.plot(secondary_y=['A', 'B'], mark_right=False)
Out[128]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d65acbb90>
```

Custom formatters for timeseries plots

Changed in version 1.0.0.

Pandas provides custom formatters for timeseries plots. These change the formatting of the axis labels for dates and times. By default, the custom formatters are applied only to plots created by pandas with `DataFrame.plot()` or `Series.plot()`. To have them apply to all plots, including those made by matplotlib, set the option `pd.options.plotting.matplotlib.register_converters = True` or use `pandas.plotting.register_matplotlib_converters()`.

Suppressing tick resolution adjustment

pandas includes automatic tick resolution adjustment for regular frequency time-series data. For limited cases where pandas cannot infer the frequency information (e.g., in an externally created `twinx`), you can choose to suppress this behavior for alignment purposes.

Here is the default behavior, notice how the x-axis tick labeling is performed:

```
In [129]: plt.figure()
Out[129]: <Figure size 640x480 with 0 Axes>

In [130]: df['A'].plot()
Out[130]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d64a838d0>
```

Using the `x_compat` parameter, you can suppress this behavior:

```
In [131]: plt.figure()
Out[131]: <Figure size 640x480 with 0 Axes>

In [132]: df['A'].plot(x_compat=True)
Out[132]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d66c94790>
```

If you have more than one plot that needs to be suppressed, the `use` method in `pandas.plotting.plot_params` can be used in a `with` statement:

```
In [133]: plt.figure()
Out[133]: <Figure size 640x480 with 0 Axes>

In [134]: with pd.plotting.plot_params.use('x_compat', True):
.....:     df['A'].plot(color='r')
.....:     df['B'].plot(color='g')
.....:     df['C'].plot(color='b')
.....:
```

Automatic date tick adjustment

TimedeltaIndex now uses the native matplotlib tick locator methods, it is useful to call the automatic date tick adjustment from matplotlib for figures whose ticklabels overlap.

See the `autofmt_xdate` method and the [matplotlib documentation](#) for more.

Subplots

Each Series in a DataFrame can be plotted on a different axis with the `subplots` keyword:

```
In [135]: df.plot(subplots=True, figsize=(6, 6));
```

Using layout and targeting multiple axes

The layout of subplots can be specified by the `layout` keyword. It can accept `(rows, columns)`. The `layout` keyword can be used in `hist` and `boxplot` also. If the input is invalid, a `ValueError` will be raised.

The number of axes which can be contained by rows x columns specified by `layout` must be larger than the number of required subplots. If layout can contain more axes than required, blank axes are not drawn. Similar to a NumPy array's `reshape` method, you can use `-1` for one dimension to automatically calculate the number of rows or columns needed, given the other.

```
In [136]: df.plot(subplots=True, layout=(2, 3), figsize=(6, 6), sharex=False);
```

The above example is identical to using:

```
In [137]: df.plot(subplots=True, layout=(2, -1), figsize=(6, 6), sharex=False);
```

The required number of columns (3) is inferred from the number of series to plot and the given number of rows (2).

You can pass multiple axes created beforehand as list-like via `ax` keyword. This allows more complicated layouts. The passed axes must be the same number as the subplots being drawn.

When multiple axes are passed via the `ax` keyword, `layout`, `sharex` and `sharey` keywords don't affect to the output. You should explicitly pass `sharex=False` and `sharey=False`, otherwise you will see a warning.

```
In [138]: fig, axes = plt.subplots(4, 4, figsize=(6, 6))

In [139]: plt.subplots_adjust(wspace=0.5, hspace=0.5)

In [140]: target1 = [axes[0][0], axes[1][1], axes[2][2], axes[3][3]]

In [141]: target2 = [axes[3][0], axes[2][1], axes[1][2], axes[0][3]]

In [142]: df.plot(subplots=True, ax=target1, legend=False, sharex=False,
   ↪sharey=False);

In [143]: (-df).plot(subplots=True, ax=target2, legend=False,
   .....:           sharex=False, sharey=False);
   .....:
```

Another option is passing an `ax` argument to `Series.plot()` to plot on a particular axis:

```
In [144]: fig, axes = plt.subplots(nrows=2, ncols=2)

In [145]: df['A'].plot(ax=axes[0, 0]);

In [146]: axes[0, 0].set_title('A');

In [147]: df['B'].plot(ax=axes[0, 1]);

In [148]: axes[0, 1].set_title('B');

In [149]: df['C'].plot(ax=axes[1, 0]);

In [150]: axes[1, 0].set_title('C');
```

(continues on next page)

(continued from previous page)

```
In [151]: df['D'].plot(ax=axes[1, 1]);
In [152]: axes[1, 1].set_title('D');
```

Plotting with error bars

Plotting with error bars is supported in `DataFrame.plot()` and `Series.plot()`.

Horizontal and vertical error bars can be supplied to the `xerr` and `yerr` keyword arguments to `plot()`. The error values can be specified using a variety of formats:

- As a `DataFrame` or `dict` of errors with column names matching the `columns` attribute of the plotting `DataFrame` or matching the `name` attribute of the `Series`.
- As a `str` indicating which of the columns of plotting `DataFrame` contain the error values.
- As raw values (list, tuple, or `np.ndarray`). Must be the same length as the plotting `DataFrame/Series`.

Asymmetrical error bars are also supported, however raw error values must be provided in this case. For a `M` length `Series`, a `Mx2` array should be provided indicating lower and upper (or left and right) errors. For a `MxN` `DataFrame`, asymmetrical errors should be in a `Mx2xN` array.

Here is an example of one way to easily plot group means with standard deviations from the raw data.

```
# Generate the data
In [153]: ix3 = pd.MultiIndex.from_arrays([
.....:     ['a', 'a', 'a', 'a', 'b', 'b', 'b', 'b'],
.....:     ['foo', 'foo', 'bar', 'bar', 'foo', 'foo', 'bar', 'bar']],
.....:     names=['letter', 'word'])
.....:

In [154]: df3 = pd.DataFrame({'data1': [3, 2, 4, 3, 2, 4, 3, 2],
.....:                           'data2': [6, 5, 7, 5, 4, 5, 6, 5]}, index=ix3)
.....:

# Group by index labels and take the means and standard deviations
# for each group
In [155]: gp3 = df3.groupby(level=('letter', 'word'))

In [156]: means = gp3.mean()

In [157]: errors = gp3.std()

In [158]: means
Out[158]:
      data1  data2
letter word
a      bar    3.5   6.0
      foo    2.5   5.5
b      bar    2.5   5.5
      foo    3.0   4.5

In [159]: errors
Out[159]:
      data1      data2
letter word
a      bar  0.707107  1.414214
      foo  0.707107  0.707107
b      bar  0.707107  0.707107
      foo  1.414214  0.707107

# Plot
In [160]: fig, ax = plt.subplots()

In [161]: means.plot.bar(yerr=errors, ax=ax, capsized=4)
Out[161]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d6532c0d0>
```

Plotting tables

Plotting with matplotlib table is now supported in `DataFrame.plot()` and `Series.plot()` with a `table` keyword. The `table` keyword can accept `bool`, `DataFrame` or `Series`. The simple way to draw a table is to specify `table=True`. Data will be transposed to meet matplotlib's default layout.

```
In [162]: fig, ax = plt.subplots(1, 1)

In [163]: df = pd.DataFrame(np.random.rand(5, 3), columns=['a', 'b', 'c'])

In [164]: ax.get_xaxis().set_visible(False)    # Hide Ticks

In [165]: df.plot(table=True, ax=ax)
Out[165]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d64d59a50>
```

Also, you can pass a different DataFrame or Series to the `table` keyword. The data will be drawn as displayed in print method (not transposed automatically). If required, it should be transposed manually as seen in the example below.

```
In [166]: fig, ax = plt.subplots(1, 1)

In [167]: ax.get_xaxis().set_visible(False)      # Hide Ticks

In [168]: df.plot(table=np.round(df.T, 2), ax=ax)
Out[168]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d674f0e10>
```

There also exists a helper function `pandas.plotting.table`, which creates a table from `DataFrame` or `Series`, and adds it to an `matplotlib.Axes` instance. This function can accept keywords which the `matplotlib.table` has.

```
In [169]: from pandas.plotting import table

In [170]: fig, ax = plt.subplots(1, 1)

In [171]: table(ax, np.round(df.describe(), 2),
.....:     loc='upper right', colWidths=[0.2, 0.2, 0.2])
.....:
Out[171]: <matplotlib.table.Table at 0x7f6d76575910>

In [172]: df.plot(ax=ax, ylim=(0, 2), legend=None)
Out[172]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d669dfd50>
```

Note: You can get table instances on the axes using `axes.tables` property for further decorations. See the [matplotlib table documentation](#) for more.

Colormaps

A potential issue when plotting a large number of columns is that it can be difficult to distinguish some series due to repetition in the default colors. To remedy this, `DataFrame` plotting supports the use of the `colormap` argument, which accepts either a Matplotlib colormap or a string that is a name of a colormap registered with Matplotlib. A visualization of the default matplotlib colormaps is available [here](#).

As matplotlib does not directly support colormaps for line-based plots, the colors are selected based on an even spacing determined by the number of columns in the `DataFrame`. There is no consideration made for background color, so some colormaps will produce lines that are not easily visible.

To use the cubehelix colormap, we can pass `colormap='cubehelix'`.

```
In [173]: df = pd.DataFrame(np.random.randn(1000, 10), index=ts.index)

In [174]: df = df.cumsum()

In [175]: plt.figure()
Out[175]: <Figure size 640x480 with 0 Axes>

In [176]: df.plot(colormap='cubehelix')
Out[176]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d652af850>
```

Alternatively, we can pass the colormap itself:

```
In [177]: from matplotlib import cm  
  
In [178]: plt.figure()  
Out[178]: <Figure size 640x480 with 0 Axes>  
  
In [179]: df.plot(colormap=cm.cubehelix)  
Out[179]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d66a16f90>
```

Colormaps can also be used other plot types, like bar charts:

```
In [180]: dd = pd.DataFrame(np.random.randn(10, 10)).applymap(abs)

In [181]: dd = dd.cumsum()

In [182]: plt.figure()
Out[182]: <Figure size 640x480 with 0 Axes>

In [183]: dd.plot.bar(colormap='Greens')
Out[183]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d66695e10>
```

Parallel coordinates charts:

```
In [184]: plt.figure()
Out[184]: <Figure size 640x480 with 0 Axes>

In [185]: parallel_coordinates(data, 'Name', colormap='gist_rainbow')
Out[185]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d6689c850>
```

Andrews curves charts:

```
In [186]: plt.figure()
Out[186]: <Figure size 640x480 with 0 Axes>

In [187]: andrews_curves(data, 'Name', colormap='winter')
Out[187]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d66b83bd0>
```

3.11.6 Plotting directly with matplotlib

In some situations it may still be preferable or necessary to prepare plots directly with matplotlib, for instance when a certain type of plot or customization is not (yet) supported by pandas. Series and DataFrame objects behave like arrays and can therefore be passed directly to matplotlib functions without explicit casts.

pandas also automatically registers formatters and locators that recognize date indices, thereby extending date and time support to practically all plot types available in matplotlib. Although this formatting does not provide the same level of refinement you would get when plotting via pandas, it can be faster when plotting a large number of points.

```
In [188]: price = pd.Series(np.random.randn(150).cumsum(),
.....:                         index=pd.date_range('2000-1-1', periods=150, freq='B'))
.....:

In [189]: ma = price.rolling(20).mean()

In [190]: mstd = price.rolling(20).std()

In [191]: plt.figure()
Out[191]: <Figure size 640x480 with 0 Axes>

In [192]: plt.plot(price.index, price, 'k')
Out[192]: [

```

(continues on next page)

(continued from previous page)

```
In [193]: plt.plot(ma.index, ma, 'b')
Out[193]: [

```

{{ header }}

3.12 Computational tools

3.12.1 Statistical functions

Percent change

Series and DataFrame have a method `pct_change()` to compute the percent change over a given number of periods (using `fill_method` to fill NA/null values *before* computing the percent change).

```
In [1]: ser = pd.Series(np.random.randn(8))
```

(continues on next page)

(continued from previous page)

In [2]: ser.pct_change()**Out[2]:**

```
0      NaN  
1    -1.111266  
2     10.485199  
3    -0.696740  
4    -3.733239  
5    -1.849970  
6     0.037593  
7    -0.414653  
dtype: float64
```

In [3]: df = pd.DataFrame(np.random.randn(10, 4))**In [4]:** df.pct_change(periods=3)**Out[4]:**

```
          0         1         2         3  
0      NaN       NaN       NaN       NaN  
1      NaN       NaN       NaN       NaN  
2      NaN       NaN       NaN       NaN  
3   -0.457531  0.646832 -0.401823 -16.097503  
4   -3.075823  1.592976 -0.237678 -1.030698  
5   -0.691741 -1.100963 -0.698905 -0.261705  
6   -2.078342 -1.442763 -7.764726 -1.623076  
7   -0.900604  0.269052 -1.966331  5.664648  
8   -4.016407 -2.167642 -2.412051  0.428739  
9   -3.310573 -4.408886 -1.281755 -0.355891
```

Covariance

Series.cov() can be used to compute covariance between series (excluding missing values).

In [5]: s1 = pd.Series(np.random.randn(1000))**In [6]:** s2 = pd.Series(np.random.randn(1000))**In [7]:** s1.cov(s2)**Out[7]:** -0.0259909834065625

Analogously, DataFrame.cov() to compute pairwise covariances among the series in the DataFrame, also excluding NA/null values.

Note: Assuming the missing data are missing at random this results in an estimate for the covariance matrix which is unbiased. However, for many applications this estimate may not be acceptable because the estimated covariance matrix is not guaranteed to be positive semi-definite. This could lead to estimated correlations having absolute values which are greater than one, and/or a non-invertible covariance matrix. See [Estimation of covariance matrices](#) for more details.

```
In [8]: frame = pd.DataFrame(np.random.randn(1000, 5),  
...:                           columns=['a', 'b', 'c', 'd', 'e'])  
...:
```

(continues on next page)

(continued from previous page)

```
In [9]: frame.cov()
Out[9]:
      a          b          c          d          e
a  0.983468 -0.011515 -0.026086 -0.029599  0.016792
b -0.011515  0.958393 -0.034534  0.029431 -0.028427
c -0.026086 -0.034534  1.005162 -0.011993  0.003532
d -0.029599  0.029431 -0.011993  0.919243 -0.024571
e  0.016792 -0.028427  0.003532 -0.024571  0.987879
```

DataFrame.cov also supports an optional min_periods keyword that specifies the required minimum number of observations for each column pair in order to have a valid result.

```
In [10]: frame = pd.DataFrame(np.random.randn(20, 3), columns=['a', 'b', 'c'])

In [11]: frame.loc[frame.index[:5], 'a'] = np.nan

In [12]: frame.loc[frame.index[5:10], 'b'] = np.nan

In [13]: frame.cov()
Out[13]:
      a          b          c
a  0.482112 -0.432629 -0.308212
b -0.432629  0.783740  0.253589
c -0.308212  0.253589  0.781763

In [14]: frame.cov(min_periods=12)
Out[14]:
      a          b          c
a  0.482112       NaN -0.308212
b       NaN  0.783740  0.253589
c -0.308212  0.253589  0.781763
```

Correlation

Correlation may be computed using the corr() method. Using the method parameter, several methods for computing correlations are provided:

Method name	Description
pearson (default)	Standard correlation coefficient
kendall	Kendall Tau correlation coefficient
spearman	Spearman rank correlation coefficient

All of these are currently computed using pairwise complete observations. Wikipedia has articles covering the above correlation coefficients:

- Pearson correlation coefficient
- Kendall rank correlation coefficient
- Spearman's rank correlation coefficient

Note: Please see the [caveats](#) associated with this method of calculating correlation matrices in the [covariance section](#).

```
In [15]: frame = pd.DataFrame(np.random.randn(1000, 5),
.....:                      columns=['a', 'b', 'c', 'd', 'e'])
.....:

In [16]: frame.iloc[::2] = np.nan

# Series with Series
In [17]: frame['a'].corr(frame['b'])
Out[17]: -0.016100228337092945

In [18]: frame['a'].corr(frame['b'], method='spearman')
Out[18]: -0.0035841743366973465

# Pairwise correlation of DataFrame columns
In [19]: frame.corr()
Out[19]:
      a          b          c          d          e
a  1.000000 -0.016100  0.030914 -0.080693 -0.033105
b -0.016100  1.000000  0.000288 -0.058371  0.014189
c  0.030914  0.000288  1.000000 -0.047523  0.076077
d -0.080693 -0.058371 -0.047523  1.000000  0.044363
e -0.033105  0.014189  0.076077  0.044363  1.000000
```

Note that non-numeric columns will be automatically excluded from the correlation calculation.

Like `cov`, `corr` also supports the optional `min_periods` keyword:

```
In [20]: frame = pd.DataFrame(np.random.randn(20, 3), columns=['a', 'b', 'c'])

In [21]: frame.loc[frame.index[:5], 'a'] = np.nan

In [22]: frame.loc[frame.index[5:10], 'b'] = np.nan

In [23]: frame.corr()
Out[23]:
      a          b          c
a  1.000000 -0.365801 -0.396893
b -0.365801  1.000000  0.200321
c -0.396893  0.200321  1.000000

In [24]: frame.corr(min_periods=12)
Out[24]:
      a          b          c
a  1.000000      NaN -0.396893
b      NaN  1.000000  0.200321
c -0.396893  0.200321  1.000000
```

New in version 0.24.0.

The `method` argument can also be a callable for a generic correlation calculation. In this case, it should be a single function that produces a single value from two ndarray inputs. Suppose we wanted to compute the correlation based on histogram intersection:

```
# histogram intersection
In [25]: def histogram_intersection(a, b):
.....:     return np.minimum(np.true_divide(a, a.sum()),
.....:                      np.true_divide(b, b.sum())).sum()
.....:
```

(continues on next page)

(continued from previous page)

```
In [26]: frame.corr(method=histogram_intersection)
Out[26]:
      a          b          c
a  1.000000 -2.024890 -2.290897
b -2.024890  1.000000 -3.200305
c -2.290897 -3.200305  1.000000
```

A related method `corrwith()` is implemented on DataFrame to compute the correlation between like-labeled Series contained in different DataFrame objects.

```
In [27]: index = ['a', 'b', 'c', 'd', 'e']

In [28]: columns = ['one', 'two', 'three', 'four']

In [29]: df1 = pd.DataFrame(np.random.randn(5, 4), index=index, columns=columns)

In [30]: df2 = pd.DataFrame(np.random.randn(4, 4), index=index[:4], columns=columns)

In [31]: df1.corrwith(df2)
Out[31]:
one      0.545954
two      0.777684
three     0.825365
four      0.419667
dtype: float64

In [32]: df2.corrwith(df1, axis=1)
Out[32]:
a     -0.014982
b      0.693884
c      0.823816
d      0.473178
e        NaN
dtype: float64
```

Data ranking

The `rank()` method produces a data ranking with ties being assigned the mean of the ranks (by default) for the group:

```
In [33]: s = pd.Series(np.random.randn(5), index=list('abcde'))

In [34]: s['d'] = s['b'] # so there's a tie

In [35]: s.rank()
Out[35]:
a    1.0
b    3.5
c    2.0
d    3.5
e    5.0
dtype: float64
```

`rank()` is also a DataFrame method and can rank either the rows (`axis=0`) or the columns (`axis=1`). `NaN` values are excluded from the ranking.

```
In [36]: df = pd.DataFrame(np.random.randn(10, 6))

In [37]: df[4] = df[2][:5] # some ties

In [38]: df
Out[38]:
   0      1      2      3      4      5
0 -0.017556 -1.306936 1.394535 0.820200 1.394535 -0.781559
1  0.674253 -1.447310 0.943797 0.175342 0.943797 -0.089358
2  0.525133  0.161677 0.329120 0.199401 0.329120 -0.423969
3  0.008157 -0.251529 -0.339662 -1.230552 -0.339662  0.311509
4 -0.099249  1.032490 0.442117 0.112822 0.442117  0.620003
5 -0.928569  1.696775 1.169352 -0.837321      NaN -0.259138
6 -1.354065  2.727253 -0.148248 1.146235      NaN -1.605315
7  0.104505 -1.542295 -0.544195 1.422024      NaN -0.712611
8  1.969631  0.275301 0.159377 0.355363      NaN -0.037047
9  1.214105  0.798272 1.299685 0.446696      NaN -0.474808

In [39]: df.rank(1)
Out[39]:
   0      1      2      3      4      5
0  3.0   1.0   5.5   4.0   5.5   2.0
1  4.0   1.0   5.5   3.0   5.5   2.0
2  6.0   2.0   4.5   3.0   4.5   1.0
3  5.0   4.0   2.5   1.0   2.5   6.0
4  1.0   6.0   3.5   2.0   3.5   5.0
5  1.0   5.0   4.0   2.0   NaN   3.0
6  2.0   5.0   3.0   4.0   NaN   1.0
7  4.0   1.0   3.0   5.0   NaN   2.0
8  5.0   3.0   2.0   4.0   NaN   1.0
9  4.0   3.0   5.0   2.0   NaN   1.0
```

rank optionally takes a parameter ascending which by default is true; when false, data is reverse-ranked, with larger values assigned a smaller rank.

rank supports different tie-breaking methods, specified with the method parameter:

- average : average rank of tied group
- min : lowest rank in the group
- max : highest rank in the group
- first : ranks assigned in the order they appear in the array

3.12.2 Window Functions

For working with data, a number of window functions are provided for computing common *window* or *rolling* statistics. Among these are count, sum, mean, median, correlation, variance, covariance, standard deviation, skewness, and kurtosis.

The rolling() and expanding() functions can be used directly from DataFrameGroupBy objects, see the [groupby docs](#).

Note: The API for window statistics is quite similar to the way one works with GroupBy objects, see the documentation [here](#).

We work with rolling, expanding and exponentially weighted data through the corresponding objects, Rolling, Expanding and EWM.

```
In [40]: s = pd.Series(np.random.randn(1000),
.....                         index=pd.date_range('1/1/2000', periods=1000))
....:

In [41]: s = s.cumsum()

In [42]: s
Out[42]:
2000-01-01    -1.634926
2000-01-02    -0.587365
2000-01-03     1.090469
2000-01-04     0.751888
2000-01-05     0.666996
...
2002-09-22    -2.253101
2002-09-23    -1.961567
2002-09-24    -1.612239
2002-09-25    -2.357398
2002-09-26    -3.686361
Freq: D, Length: 1000, dtype: float64
```

These are created from methods on Series and DataFrame.

```
In [43]: r = s.rolling(window=60)

In [44]: r
Out[44]: Rolling [window=60,center=False,axis=0]
```

These object provide tab-completion of the available methods and properties.

```
In [14]: r.<TAB>                                         # noqa: E225, E999
r.agg      r.apply      r.count      r.exclusions   r.max       r.median    r.
r.name    r.skew      r.sum        r.kurt        r.mean       r.min      r.
r.aggregate r.corr      r.cov        r.var         r.std        r.
r.quantile r.std       r.var
```

Generally these methods all have the same interface. They all accept the following arguments:

- window: size of moving window
- min_periods: threshold of non-null data points to require (otherwise result is NA)
- center: boolean, whether to set the labels at the center (default is False)

We can then call methods on these rolling objects. These return like-indexed objects:

```
In [45]: r.mean()
Out[45]:
2000-01-01      NaN
2000-01-02      NaN
2000-01-03      NaN
2000-01-04      NaN
2000-01-05      NaN
...
2002-09-22    -6.977288
2002-09-23    -6.892791
```

(continues on next page)

(continued from previous page)

```
2002-09-24    -6.807699
2002-09-25    -6.721276
2002-09-26    -6.664557
Freq: D, Length: 1000, dtype: float64
```

```
In [46]: s.plot(style='k--')
Out[46]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d76a93510>

In [47]: r.mean().plot(style='k')
Out[47]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d76a93510>
```

They can also be applied to DataFrame objects. This is really just syntactic sugar for applying the moving window operator to all of the DataFrame's columns:

```
In [48]: df = pd.DataFrame(np.random.randn(1000, 4),
....:                     index=pd.date_range('1/1/2000', periods=1000),
....:                     columns=['A', 'B', 'C', 'D'])

In [49]: df = df.cumsum()

In [50]: df.rolling(window=60).sum().plot(subplots=True)
Out[50]:
```

(continues on next page)

(continued from previous page)

```
array([<matplotlib.axes._subplots.AxesSubplot object at 0x7f6d75a6af50>,
       <matplotlib.axes._subplots.AxesSubplot object at 0x7f6d75a2d590>,
       <matplotlib.axes._subplots.AxesSubplot object at 0x7f6d759e36d0>,
       <matplotlib.axes._subplots.AxesSubplot object at 0x7f6d759997d0>],
      dtype=object)
```

Method summary

We provide a number of common statistical functions:

Method	Description
count()	Number of non-null observations
sum()	Sum of values
mean()	Mean of values
median()	Arithmetic median of values
min()	Minimum
max()	Maximum
std()	Bessel-corrected sample standard deviation
var()	Unbiased variance
skew()	Sample skewness (3rd moment)
kurt()	Sample kurtosis (4th moment)
quantile()	Sample quantile (value at %)
apply()	Generic apply
cov()	Unbiased covariance (binary)
corr()	Correlation (binary)

Rolling Apply

The `apply()` function takes an extra `func` argument and performs generic rolling computations. The `func` argument should be a single function that produces a single value from an ndarray input. Suppose we wanted to compute the mean absolute deviation on a rolling basis:

```
In [51]: def mad(x):
....:     return np.fabs(x - x.mean()).mean()
....:

In [52]: s.rolling(window=60).apply(mad, raw=True).plot(style='k')
Out[52]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d7576cc0>
```

New in version 1.0.

Additionally, `apply()` can leverage Numba if installed as an optional dependency. The apply aggregation can be executed using Numba by specifying `engine='numba'` and `engine_kwargs` arguments (`raw` must also be set to `True`). Numba will be applied in potentially two routines:

1. If `func` is a standard Python function, the engine will JIT the passed function. `func` can also be a JITed function in which case the engine will not JIT the function again.
2. The engine will JIT the for loop where the apply function is applied to each window.

The `engine_kwargs` argument is a dictionary of keyword arguments that will be passed into the `numba.jit` decorator. These keyword arguments will be applied to *both* the passed function (if a standard Python function) and the apply for loop over each window. Currently only `nogil`, `nopython`, and `parallel` are supported, and their default values are set to `False`, `True` and `False` respectively.

Note: In terms of performance, **the first time a function is run using the Numba engine will be slow** as Numba will have some function compilation overhead. However, `rolling` objects will cache the function and subsequent calls will be fast. In general, the Numba engine is performant with a larger amount of data points (e.g. 1+ million).

```
In [1]: data = pd.Series(range(1_000_000))
```

```
In [2]: roll = data.rolling(10)
```

```
In [3]: def f(x):
```

(continues on next page)

(continued from previous page)

```
....:     return np.sum(x) + 5
# Run the first time, compilation time will affect performance
In [4]: %timeit -r 1 -n 1 roll.apply(f, engine='numba', raw=True) # noqa: E225
1.23 s ± 0 ns per loop (mean ± std. dev. of 1 run, 1 loop each)
# Function is cached and performance will improve
In [5]: %timeit roll.apply(f, engine='numba', raw=True)
188 ms ± 1.93 ms per loop (mean ± std. dev. of 7 runs, 10 loops each)

In [6]: %timeit roll.apply(f, engine='cython', raw=True)
3.92 s ± 59 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)
```

Rolling windows

Passing `win_type` to `.rolling` generates a generic rolling window computation, that is weighted according the `win_type`. The following methods are available:

Method	Description
<code>sum()</code>	Sum of values
<code>mean()</code>	Mean of values

The weights used in the window are specified by the `win_type` keyword. The list of recognized types are the `scipy.signal` window functions:

- `boxcar`
- `triang`
- `blackman`
- `hamming`
- `bartlett`
- `parzen`
- `bohman`
- `blackmanharris`
- `nuttall`
- `barthann`
- `kaiser` (needs beta)
- `gaussian` (needs std)
- `general_gaussian` (needs power, width)
- `slepian` (needs width)
- `exponential` (needs tau).

```
In [53]: ser = pd.Series(np.random.randn(10),
....:                     index=pd.date_range('1/1/2000', periods=10))
....:

In [54]: ser.rolling(window=5, win_type='triang').mean()
Out[54]:
```

(continues on next page)

(continued from previous page)

2000-01-01	NaN
2000-01-02	NaN
2000-01-03	NaN
2000-01-04	NaN
2000-01-05	-0.123174
2000-01-06	-0.000860
2000-01-07	-0.292506
2000-01-08	-0.620723
2000-01-09	-0.707556
2000-01-10	-0.369383
Freq:	D, dtype: float64

Note that the `boxcar` window is equivalent to `mean()`.

```
In [55]: ser.rolling(window=5, win_type='boxcar').mean()
Out[55]:
```

2000-01-01	NaN
2000-01-02	NaN
2000-01-03	NaN
2000-01-04	NaN
2000-01-05	0.059575
2000-01-06	-0.374478

2000-01-08	-0.160119
2000-01-09	-0.613105
2000-01-10	-0.490837
Freq:	D, dtype: float64

```
In [56]: ser.rolling(window=5).mean()
Out[56]:
```

2000-01-01	NaN
2000-01-02	NaN
2000-01-03	NaN
2000-01-04	NaN
2000-01-05	0.059575
2000-01-06	-0.374478
2000-01-07	-0.505983
2000-01-08	-0.160119
2000-01-09	-0.613105
2000-01-10	-0.490837
Freq:	D, dtype: float64

For some windowing functions, additional parameters must be specified:

```
In [57]: ser.rolling(window=5, win_type='gaussian').mean(std=0.1)
Out[57]:
```

2000-01-01	NaN
2000-01-02	NaN
2000-01-03	NaN
2000-01-04	NaN
2000-01-05	-1.426737
2000-01-06	1.501346
2000-01-07	0.288700
2000-01-08	-2.181387
2000-01-09	-0.711838
2000-01-10	0.302582
Freq:	D, dtype: float64

Note: For `.sum()` with a `win_type`, there is no normalization done to the weights for the window. Passing custom weights of [1, 1, 1] will yield a different result than passing weights of [2, 2, 2], for example. When passing a `win_type` instead of explicitly specifying the weights, the weights are already normalized so that the largest weight is 1.

In contrast, the nature of the `.mean()` calculation is such that the weights are normalized with respect to each other. Weights of [1, 1, 1] and [2, 2, 2] yield the same result.

Time-aware rolling

It is possible to pass an offset (or convertible) to a `.rolling()` method and have it produce variable sized windows based on the passed time window. For each time point, this includes all preceding values occurring within the indicated time delta.

This can be particularly useful for a non-regular time frequency index.

```
In [58]: dft = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]},  
....:                         index=pd.date_range('20130101 09:00:00',  
....:                                     periods=5,  
....:                                     freq='s'))  
....:  
  
In [59]: dft  
Out[59]:  
          B  
2013-01-01 09:00:00  0.0  
2013-01-01 09:00:01  1.0  
2013-01-01 09:00:02  2.0  
2013-01-01 09:00:03  NaN  
2013-01-01 09:00:04  4.0
```

This is a regular frequency index. Using an integer window parameter works to roll along the window frequency.

```
In [60]: dft.rolling(2).sum()  
Out[60]:  
          B  
2013-01-01 09:00:00  NaN  
2013-01-01 09:00:01  1.0  
2013-01-01 09:00:02  3.0  
2013-01-01 09:00:03  NaN  
2013-01-01 09:00:04  NaN  
  
In [61]: dft.rolling(2, min_periods=1).sum()  
Out[61]:  
          B  
2013-01-01 09:00:00  0.0  
2013-01-01 09:00:01  1.0  
2013-01-01 09:00:02  3.0  
2013-01-01 09:00:03  2.0  
2013-01-01 09:00:04  4.0
```

Specifying an offset allows a more intuitive specification of the rolling frequency.

```
In [62]: dft.rolling('2s').sum()  
Out[62]:
```

(continues on next page)

(continued from previous page)

	B
2013-01-01 09:00:00	0.0
2013-01-01 09:00:01	1.0
2013-01-01 09:00:02	3.0
2013-01-01 09:00:03	2.0
2013-01-01 09:00:04	4.0

Using a non-regular, but still monotonic index, rolling with an integer window does not impart any special calculation.

```
In [63]: dft = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]},  
....:  
....:  
....:  
....:  
....:  
....:  
....:  
....:  
....:  
  
In [64]: dft  
Out[64]:  
          B  
foo  
2013-01-01 09:00:00    0.0  
2013-01-01 09:00:02    1.0  
2013-01-01 09:00:03    2.0  
2013-01-01 09:00:05    NaN  
2013-01-01 09:00:06    4.0  
  
In [65]: dft.rolling(2).sum()  
Out[65]:  
          B  
foo  
2013-01-01 09:00:00    NaN  
2013-01-01 09:00:02    1.0  
2013-01-01 09:00:03    3.0  
2013-01-01 09:00:05    NaN  
2013-01-01 09:00:06    NaN
```

Using the time-specification generates variable windows for this sparse data.

```
In [66]: dft.rolling('2s').sum()  
Out[66]:  
          B  
foo  
2013-01-01 09:00:00    0.0  
2013-01-01 09:00:02    1.0  
2013-01-01 09:00:03    3.0  
2013-01-01 09:00:05    NaN  
2013-01-01 09:00:06    4.0
```

Furthermore, we now allow an optional `on` parameter to specify a column (rather than the default of the index) in a DataFrame.

```
In [67]: dft = dft.reset_index()  
  
In [68]: dft
```

(continues on next page)

(continued from previous page)

```
Out[68]:
      foo      B
0 2013-01-01 09:00:00  0.0
1 2013-01-01 09:00:02  1.0
2 2013-01-01 09:00:03  2.0
3 2013-01-01 09:00:05  NaN
4 2013-01-01 09:00:06  4.0

In [69]: dft.rolling('2s', on='foo').sum()
Out[69]:
      foo      B
0 2013-01-01 09:00:00  0.0
1 2013-01-01 09:00:02  1.0
2 2013-01-01 09:00:03  3.0
3 2013-01-01 09:00:05  NaN
4 2013-01-01 09:00:06  4.0
```

Custom window rolling

New in version 1.0.

In addition to accepting an integer or offset as a window argument, `rolling` also accepts a `BaseIndexer` subclass that allows a user to define a custom method for calculating window bounds. The `BaseIndexer` subclass will need to define a `get_window_bounds` method that returns a tuple of two arrays, the first being the starting indices of the windows and second being the ending indices of the windows. Additionally, `num_values`, `min_periods`, `center`, `closed` and will automatically be passed to `get_window_bounds` and the defined method must always accept these arguments.

For example, if we have the following DataFrame:

```
In [70]: use_expanding = [True, False, True, False, True]

In [71]: use_expanding
Out[71]: [True, False, True, False, True]

In [72]: df = pd.DataFrame({'values': range(5)})

In [73]: df
Out[73]:
   values
0       0
1       1
2       2
3       3
4       4
```

and we want to use an expanding window where `use_expanding` is `True` otherwise a window of size 1, we can create the following `BaseIndexer`:

```
In [2]: from pandas.api.indexers import BaseIndexer
....:
....: class CustomIndexer(BaseIndexer):
....:
....:     def get_window_bounds(self, num_values, min_periods, center, closed):
....:         start = np.empty(num_values, dtype=np.int64)
```

(continues on next page)

(continued from previous page)

```

....:         end = np.empty(num_values, dtype=np.int64)
....:         for i in range(num_values):
....:             if self.use_expanding[i]:
....:                 start[i] = 0
....:                 end[i] = i + 1
....:             else:
....:                 start[i] = i
....:                 end[i] = i + self.window_size
....:         return start, end
....:

In [3]: indexer = CustomIndexer(window_size=1, use_expanding=use_expanding)

In [4]: df.rolling(indexer).sum()
Out[4]:
   values
0      0.0
1      1.0
2      3.0
3      3.0
4     10.0

```

Rolling window endpoints

The inclusion of the interval endpoints in rolling window calculations can be specified with the `closed` parameter:

<code>closed</code>	Description	Default for
<code>right</code>	close right endpoint	time-based windows
<code>left</code>	close left endpoint	
<code>both</code>	close both endpoints	fixed windows
<code>neither</code>	open endpoints	

For example, having the right endpoint open is useful in many problems that require that there is no contamination from present information back to past information. This allows the rolling window to compute statistics “up to that point in time”, but not including that point in time.

```

In [74]: df = pd.DataFrame({'x': 1,
....:                         index=[pd.Timestamp('20130101 09:00:01'),
....:                                pd.Timestamp('20130101 09:00:02'),
....:                                pd.Timestamp('20130101 09:00:03'),
....:                                pd.Timestamp('20130101 09:00:04'),
....:                                pd.Timestamp('20130101 09:00:06')])
....:

In [75]: df["right"] = df.rolling('2s', closed='right').x.sum() # default

In [76]: df["both"] = df.rolling('2s', closed='both').x.sum()

In [77]: df["left"] = df.rolling('2s', closed='left').x.sum()

In [78]: df["neither"] = df.rolling('2s', closed='neither').x.sum()

In [79]: df
Out[79]:

```

(continues on next page)

(continued from previous page)

	x	right	both	left	neither
2013-01-01	09:00:01	1	1.0	1.0	NaN
2013-01-01	09:00:02	1	2.0	2.0	1.0
2013-01-01	09:00:03	1	2.0	3.0	2.0
2013-01-01	09:00:04	1	2.0	3.0	2.0
2013-01-01	09:00:06	1	1.0	2.0	1.0

Currently, this feature is only implemented for time-based windows. For fixed windows, the closed parameter cannot be set and the rolling window will always have both endpoints closed.

Time-aware rolling vs. resampling

Using `.rolling()` with a time-based index is quite similar to `resampling`. They both operate and perform reductive operations on time-indexed pandas objects.

When using `.rolling()` with an offset. The offset is a time-delta. Take a backwards-in-time looking window, and aggregate all of the values in that window (including the end-point, but not the start-point). This is the new value at that point in the result. These are variable sized windows in time-space for each point of the input. You will get a same sized result as the input.

When using `.resample()` with an offset. Construct a new index that is the frequency of the offset. For each frequency bin, aggregate points from the input within a backwards-in-time looking window that fall in that bin. The result of this aggregation is the output for that frequency point. The windows are fixed size in the frequency space. Your result will have the shape of a regular frequency between the min and the max of the original input object.

To summarize, `.rolling()` is a time-based window operation, while `.resample()` is a frequency-based window operation.

Centering windows

By default the labels are set to the right edge of the window, but a `center` keyword is available so the labels can be set at the center.

```

Binary window functions

`cov()` and `corr()` can compute moving window statistics about two Series or any combination of DataFrame/Series or DataFrame/DataFrame. Here is the behavior in each case:

- two Series: compute the statistic for the pairing.
- DataFrame/Series: compute the statistics for each column of the DataFrame with the passed Series, thus returning a DataFrame.
- DataFrame/DataFrame: by default compute the statistic for matching column names, returning a DataFrame. If the keyword argument `pairwise=True` is passed then computes the statistic for each pair of columns, returning a MultiIndexed DataFrame whose index are the dates in question (see [the next section](#)).

For example:

```
In [82]: df = pd.DataFrame(np.random.randn(1000, 4),
....:                      index=pd.date_range('1/1/2000', periods=1000),
....:                      columns=['A', 'B', 'C', 'D'])
....:

In [83]: df = df.cumsum()

In [84]: df2 = df[:20]

In [85]: df2.rolling(window=5).corr(df2['B'])
Out[85]:

```

Computing rolling pairwise covariances and correlations

In financial data analysis and other fields it's common to compute covariance and correlation matrices for a collection of time series. Often one is also interested in moving-window covariance and correlation matrices. This can be done by passing the `pairwise` keyword argument, which in the case of `DataFrame` inputs will yield a MultiIndexed `DataFrame` whose index are the dates in question. In the case of a single `DataFrame` argument the `pairwise` argument can even be omitted:

Note: Missing values are ignored and each entry is computed using the pairwise complete observations. Please see the [covariance section](#) for [caveats](#) associated with this method of calculating covariance and correlation matrices.

```
In [86]: covs = (df[['B', 'C', 'D']].rolling(window=50)
....:                               .cov(df[['A', 'B', 'C']], pairwise=True))
....:
```

```
In [87]: covs.loc['2002-09-22':]
```

```
Out[87]:
```

D	0.236460	-0.879444	0.335794	1.000000

You can efficiently retrieve the time series of correlations between two columns by reshaping and indexing:

```
In [90]: correls.unstack(1)[('A', 'C')].plot()
Out[90]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d7557da10>
```

3.12.3 Aggregation

Once the Rolling, Expanding or EWM objects have been created, several methods are available to perform multiple computations on the data. These operations are similar to the [aggregating API](#), [groupby API](#), and [resample API](#).

```
In [91]: dfa = pd.DataFrame(np.random.randn(1000, 3),
.....:                         index=pd.date_range('1/1/2000', periods=1000),
.....:                         columns=['A', 'B', 'C'])
.....:

In [92]: r = dfa.rolling(window=60, min_periods=1)
```

(continues on next page)

(continued from previous page)

```
In [93]: r
Out[93]: Rolling [window=60,min_periods=1,center=False,axis=0]
```

We can aggregate by passing a function to the entire DataFrame, or select a Series (or multiple Series) via standard `__getitem__`.

```
In [94]: r.aggregate(np.sum)
Out[94]:
          A          B          C
2000-01-01  1.273375  0.351479 -0.057404

...
          ...        ...
2002-09-22 -3.624050 -7.657653
2002-09-23 -3.918048 -8.372232
2002-09-24 -2.121388 -7.715491
2002-09-25 -2.455337 -9.671716
2002-09-26 -1.719290 -8.522906
```

[1000 rows x 2 columns]

As you can see, the result of the aggregation will have the selected columns, or all columns if none are selected.

Applying multiple functions

With windowed Series you can also pass a list of functions to do aggregation with, outputting a DataFrame:

```
In [97]: r['A'].agg([np.sum, np.mean, np.std])
```

```
Out[97]:
```

	sum	mean	std
2000-01-01	1.273375	1.273375	NaN
2000-01-02	0.956484	0.478242	1.124488
2000-01-03	1.588654	0.529551	0.800084
2000-01-04	-0.313622	-0.078406	1.380291
2000-01-05	-1.332551	-0.266510	1.267209
...
2002-09-22	-3.624050	-0.060401	0.958783
2002-09-23	-3.918048	-0.065301	0.963296
2002-09-24	-2.121388	-0.035356	0.938440
2002-09-25	-2.455337	-0.040922	0.939203
2002-09-26	-1.719290	-0.028655	0.937447

[1000 rows x 3 columns]

On a windowed DataFrame, you can pass a list of functions to apply to each column, which produces an aggregated result with a hierarchical index:

```
In [98]: r.agg([np.sum, np.mean])
```

```
Out[98]:
```

	A		B		C	
	sum	mean	sum	mean	sum	mean
2000-01-01	1.273375	1.273375	0.351479	0.351479	-0.057404	-0.057404
2000-01-02	0.956484	0.478242	1.446864	0.723432	0.639892	0.319946
2000-01-03	1.588654	0.529551	1.871839	0.623946	1.468111	0.489370
2000-01-04	-0.313622	-0.078406	1.138093	0.284523	2.033807	0.508452
2000-01-05	-1.332551	-0.266510	0.219170	0.043834	2.917980	0.583596
...
2002-09-22	-3.624050	-0.060401	-7.657653	-0.127628	7.335871	0.122265
2002-09-23	-3.918048	-0.065301	-8.372232	-0.139537	7.985523	0.133092
2002-09-24	-2.121388	-0.035356	-7.715491	-0.128592	7.406371	0.123440
2002-09-25	-2.455337	-0.040922	-9.671716	-0.161195	7.641135	0.127352
2002-09-26	-1.719290	-0.028655	-8.522906	-0.142048	6.950141	0.115836

[1000 rows x 6 columns]

Passing a dict of functions has different behavior by default, see the next section.

Applying different functions to DataFrame columns

By passing a dict to aggregate you can apply a different aggregation to the columns of a DataFrame:

```
In [99]: r.agg({'A': np.sum, 'B': lambda x: np.std(x, ddof=1)})
```

```
Out[99]:
```

	A	B
2000-01-01	1.273375	NaN
2000-01-02	0.956484	0.526021
2000-01-03	1.588654	0.409928
2000-01-04	-0.313622	0.756875
2000-01-05	-1.332551	0.848116

(continues on next page)

(continued from previous page)

```
...          ...          ...
2002-09-22 -3.624050  0.857646
2002-09-23 -3.918048  0.844876
2002-09-24 -2.121388  0.832594
2002-09-25 -2.455337  0.848275
2002-09-26 -1.719290  0.844446

[1000 rows x 2 columns]
```

The function names can also be strings. In order for a string to be valid it must be implemented on the windowed object

```
In [100]: r.agg({'A': 'sum', 'B': 'std'})
```

```
Out[100]:
```

```
          A          B
2000-01-01 1.273375      NaN
2000-01-02 0.956484  0.526021
2000-01-03 1.588654  0.409928
2000-01-04 -0.313622  0.756875
2000-01-05 -1.332551  0.848116
...
          ...          ...
2002-09-22 -3.624050  0.857646
2002-09-23 -3.918048  0.844876
2002-09-24 -2.121388  0.832594
2002-09-25 -2.455337  0.848275
2002-09-26 -1.719290  0.844446
```

```
[1000 rows x 2 columns]
```

Furthermore you can pass a nested dict to indicate different aggregations on different columns.

```
In [101]: r.agg({'A': ['sum', 'std'], 'B': ['mean', 'std']})
```

```
Out[101]:
```

```
          A          B
              sum      std      mean      std
2000-01-01 1.273375      NaN  0.351479      NaN
2000-01-02 0.956484  1.124488  0.723432  0.526021
2000-01-03 1.588654  0.800084  0.623946  0.409928
2000-01-04 -0.313622  1.380291  0.284523  0.756875
2000-01-05 -1.332551  1.267209  0.043834  0.848116
...
          ...          ...          ...
2002-09-22 -3.624050  0.958783 -0.127628  0.857646

```

3.12.4 Expanding windows

A common alternative to rolling statistics is to use an *expanding* window, which yields the value of the statistic with all the data available up to that point in time.

These follow a similar interface to `.rolling`, with the `.expanding` method returning an `Expanding` object.

As these calculations are a special case of rolling statistics, they are implemented in pandas such that the following two calls are equivalent:

```
In [102]: df.rolling(window=len(df), min_periods=1).mean() [:5]
Out[102]:
```

	A	B	C	D
2000-01-01	-1.499360	-0.905903	1.148695	0.337755
2000-01-02	-1.370946	-1.714557	1.338277	-0.277116
2000-01-03	-1.211240	-2.140414	1.553466	-0.296951
2000-01-04	-1.308853	-2.155548	1.604429	-0.097598
2000-01-05	-1.191709	-2.455649	1.628346	-0.402069

```
In [103]: df.expanding(min_periods=1).mean() [:5]
```

```
Out[103]:
```

	A	B	C	D
2000-01-01	-1.499360	-0.905903	1.148695	0.337755
2000-01-02	-1.370946	-1.714557	1.338277	-0.277116
2000-01-03	-1.211240	-2.140414	1.553466	-0.296951
2000-01-04	-1.308853	-2.155548	1.604429	-0.097598
2000-01-05	-1.191709	-2.455649	1.628346	-0.402069

These have a similar set of methods to `.rolling` methods.

Method summary

Function	Description
count()	Number of non-null observations
sum()	Sum of values
mean()	Mean of values
median()	Arithmetic median of values
min()	Minimum
max()	Maximum
std()	Unbiased standard deviation
var()	Unbiased variance
skew()	Unbiased skewness (3rd moment)
kurt()	Unbiased kurtosis (4th moment)
quantile()	Sample quantile (value at %)
apply()	Generic apply
cov()	Unbiased covariance (binary)
corr()	Correlation (binary)

Aside from not having a `window` parameter, these functions have the same interfaces as their `.rolling` counterparts. Like above, the parameters they all accept are:

- `min_periods`: threshold of non-null data points to require. Defaults to minimum needed to compute statistic. No NaNs will be output once `min_periods` non-null data points have been seen.
- `center`: boolean, whether to set the labels at the center (default is False).

Note: The output of the `.rolling` and `.expanding` methods do not return a NaN if there are at least `min_periods` non-null values in the current window. For example:

```
In [104]: sn = pd.Series([1, 2, np.nan, 3, np.nan, 4])
```

```
In [105]: sn
```

```
Out[105]:
```

```
0    1.0  
1    2.0  
2    NaN  
3    3.0  
4    NaN  
5    4.0  
dtype: float64
```

```
In [106]: sn.rolling(2).max()
```

```
Out[106]:
```

```
0    NaN  
1    2.0  
2    NaN  
3    NaN  
4    NaN  
5    NaN  
dtype: float64
```

```
In [107]: sn.rolling(2, min_periods=1).max()
```

```
Out[107]:
```

```
0    1.0  
1    2.0  
2    2.0  
3    3.0  
4    3.0  
5    4.0  
dtype: float64
```

In case of expanding functions, this differs from `cumsum()`, `cumprod()`, `cummax()`, and `cummin()`, which return NaN in the output wherever a NaN is encountered in the input. In order to match the output of `cumsum` with `expanding`, use `fillna()`:

```
In [108]: sn.expanding().sum()
```

```
Out[108]:
```

```
0    1.0  
1    3.0  
2    3.0  
3    6.0  
4    6.0  
5   10.0  
dtype: float64
```

```
In [109]: sn.cumsum()
```

```
Out[109]:
```

```
0    1.0  
1    3.0  
2    NaN  
3    6.0  
4    NaN  
5   10.0
```

(continues on next page)

(continued from previous page)

```
dtype: float64
```

```
In [110]: sn.cumsum().fillna(method='ffill')
```

```
Out[110]:
```

0	1.0
1	3.0
2	3.0
3	6.0
4	6.0
5	10.0

```
dtype: float64
```

An expanding window statistic will be more stable (and less responsive) than its rolling window counterpart as the increasing window size decreases the relative impact of an individual data point. As an example, here is the mean() output for the previous time series dataset:

```
In [111]: s.plot(style='k--')
```

```
Out[111]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d753f7750>
```

```
In [112]: s.expanding().mean().plot(style='k')
```

```
Out[112]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d753f7750>
```

3.12.5 Exponentially weighted windows

A related set of functions are exponentially weighted versions of several of the above statistics. A similar interface to `.rolling` and `.expanding` is accessed through the `.ewm` method to receive an EWM object. A number of expanding EW (exponentially weighted) methods are provided:

Function	Description
<code>mean()</code>	EW moving average
<code>var()</code>	EW moving variance
<code>std()</code>	EW moving standard deviation
<code>corr()</code>	EW moving correlation
<code>cov()</code>	EW moving covariance

In general, a weighted moving average is calculated as

$$y_t = \frac{\sum_{i=0}^t w_i x_{t-i}}{\sum_{i=0}^t w_i},$$

where x_t is the input, y_t is the result and the w_i are the weights.

The EW functions support two variants of exponential weights. The default, `adjust=True`, uses the weights $w_i = (1 - \alpha)^i$ which gives

$$y_t = \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \dots + (1 - \alpha)^tx_0}{1 + (1 - \alpha) + (1 - \alpha)^2 + \dots + (1 - \alpha)^t}$$

When `adjust=False` is specified, moving averages are calculated as

$$\begin{aligned} y_0 &= x_0 \\ y_t &= (1 - \alpha)y_{t-1} + \alpha x_t, \end{aligned}$$

which is equivalent to using weights

$$w_i = \begin{cases} \alpha(1 - \alpha)^i & \text{if } i < t \\ (1 - \alpha)^i & \text{if } i = t. \end{cases}$$

Note: These equations are sometimes written in terms of $\alpha' = 1 - \alpha$, e.g.

$$y_t = \alpha'y_{t-1} + (1 - \alpha')x_t.$$

The difference between the above two variants arises because we are dealing with series which have finite history. Consider a series of infinite history, with `adjust=True`:

$$y_t = \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \dots}{1 + (1 - \alpha) + (1 - \alpha)^2 + \dots}$$

Noting that the denominator is a geometric series with initial term equal to 1 and a ratio of $1 - \alpha$ we have

$$\begin{aligned} y_t &= \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \dots}{\frac{1}{1 - (1 - \alpha)}} \\ &= [x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \dots]\alpha \\ &= \alpha x_t + [(1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \dots]\alpha \\ &= \alpha x_t + (1 - \alpha)[x_{t-1} + (1 - \alpha)x_{t-2} + \dots]\alpha \\ &= \alpha x_t + (1 - \alpha)y_{t-1} \end{aligned}$$

which is the same expression as `adjust=False` above and therefore shows the equivalence of the two variants for infinite series. When `adjust=False`, we have $y_0 = x_0$ and $y_t = \alpha x_t + (1 - \alpha)y_{t-1}$. Therefore, there is an assumption that x_0 is not an ordinary value but rather an exponentially weighted moment of the infinite series up to that point.

One must have $0 < \alpha \leq 1$, and while it is possible to pass α directly, it's often easier to think about either the **span**, **center of mass (com)** or **half-life** of an EW moment:

$$\alpha = \begin{cases} \frac{2}{s+1}, & \text{for span } s \geq 1 \\ \frac{1}{1+c}, & \text{for center of mass } c \geq 0 \\ 1 - \exp^{\frac{\log 0.5}{h}}, & \text{for half-life } h > 0 \end{cases}$$

One must specify precisely one of **span**, **center of mass**, **half-life** and **alpha** to the EW functions:

- **Span** corresponds to what is commonly called an “N-day EW moving average”.
- **Center of mass** has a more physical interpretation and can be thought of in terms of span: $c = (s - 1)/2$.
- **Half-life** is the period of time for the exponential weight to reduce to one half.
- **Alpha** specifies the smoothing factor directly.

Here is an example for a univariate time series:

```
In [113]: s.plot(style='k--')
Out[113]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d7537de10>

In [114]: s.ewm(span=20).mean().plot(style='k')
Out[114]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d7537de10>
```

EWM has a `min_periods` argument, which has the same meaning it does for all the `.expanding` and `.rolling` methods: no output values will be set until at least `min_periods` non-null values are encountered in the (expanding) window.

EWM also has an `ignore_na` argument, which determines how intermediate null values affect the calculation of the weights. When `ignore_na=False` (the default), weights are calculated based on absolute positions, so that intermediate null values affect the result. When `ignore_na=True`, weights are calculated by ignoring intermediate null values. For example, assuming `adjust=True`, if `ignore_na=False`, the weighted average of 3, `NaN`, 5 would be calculated as

$$\frac{(1-\alpha)^2 \cdot 3 + 1 \cdot 5}{(1-\alpha)^2 + 1}.$$

Whereas if `ignore_na=True`, the weighted average would be calculated as

$$\frac{(1-\alpha) \cdot 3 + 1 \cdot 5}{(1-\alpha) + 1}.$$

The `var()`, `std()`, and `cov()` functions have a `bias` argument, specifying whether the result should contain biased or unbiased statistics. For example, if `bias=True`, `ewmvar(x)` is calculated as `ewmvar(x) = ewma(x**2) - ewma(x)**2`; whereas if `bias=False` (the default), the biased variance statistics are scaled by debiasing factors

$$\frac{\left(\sum_{i=0}^t w_i\right)^2}{\left(\sum_{i=0}^t w_i\right)^2 - \sum_{i=0}^t w_i^2}.$$

(For $w_i = 1$, this reduces to the usual $N/(N - 1)$ factor, with $N = t + 1$.) See [Weighted Sample Variance](#) on Wikipedia for further details. {{ header }}

3.13 Group By: split-apply-combine

By “group by” we are referring to a process involving one or more of the following steps:

- **Splitting** the data into groups based on some criteria.
- **Applying** a function to each group independently.
- **Combining** the results into a data structure.

Out of these, the split step is the most straightforward. In fact, in many situations we may wish to split the data set into groups and do something with those groups. In the apply step, we might wish to do one of the following:

- **Aggregation:** compute a summary statistic (or statistics) for each group. Some examples:
 - Compute group sums or means.
 - Compute group sizes / counts.
- **Transformation:** perform some group-specific computations and return a like-indexed object. Some examples:
 - Standardize data (zscore) within a group.
 - Filling NAs within groups with a value derived from each group.
- **Filtration:** discard some groups, according to a group-wise computation that evaluates True or False. Some examples:
 - Discard data that belongs to groups with only a few members.
 - Filter out data based on the group sum or mean.
- Some combination of the above: GroupBy will examine the results of the apply step and try to return a sensibly combined result if it doesn’t fit into either of the above two categories.

Since the set of object instance methods on pandas data structures are generally rich and expressive, we often simply want to invoke, say, a DataFrame function on each group. The name GroupBy should be quite familiar to those who have used a SQL-based tool (or `itertools`), in which you can write code like:

```
SELECT Column1, Column2, mean(Column3), sum(Column4)
FROM SomeTable
GROUP BY Column1, Column2
```

We aim to make operations like this natural and easy to express using pandas. We’ll address each area of GroupBy functionality then provide some non-trivial examples / use cases.

See the [cookbook](#) for some advanced strategies.

3.13.1 Splitting an object into groups

pandas objects can be split on any of their axes. The abstract definition of grouping is to provide a mapping of labels to group names. To create a GroupBy object (more on what the GroupBy object is later), you may do the following:

```
In [1]: df = pd.DataFrame([('bird', 'Falconiformes', 389.0),
...:                      ('bird', 'Psittaciformes', 24.0),
...:                      ('mammal', 'Carnivora', 80.2),
...:                      ('mammal', 'Primates', np.nan),
...:                      ('mammal', 'Carnivora', 58)],
...:                     index=['falcon', 'parrot', 'lion', 'monkey', 'leopard'],
...:                     columns=['class', 'order', 'max_speed'])

In [2]: df
Out[2]:
      class          order  max_speed
falcon    bird  Falconiformes     389.0
parrot    bird  Psittaciformes     24.0
lion      mammal        Carnivora     80.2
monkey    mammal        Primates      NaN
leopard   mammal        Carnivora     58.0

# default is axis=0
In [3]: grouped = df.groupby('class')

In [4]: grouped = df.groupby('order', axis='columns')

In [5]: grouped = df.groupby(['class', 'order'])
```

The mapping can be specified many different ways:

- A Python function, to be called on each of the axis labels.
- A list or NumPy array of the same length as the selected axis.
- A dict or Series, providing a label → group name mapping.
- For DataFrame objects, a string indicating a column to be used to group. Of course `df.groupby('A')` is just syntactic sugar for `df.groupby(df['A'])`, but it makes life simpler.
- For DataFrame objects, a string indicating an index level to be used to group.
- A list of any of the above things.

Collectively we refer to the grouping objects as the **keys**. For example, consider the following DataFrame:

Note: A string passed to `groupby` may refer to either a column or an index level. If a string matches both a column name and an index level name, a `ValueError` will be raised.

```
In [6]: df = pd.DataFrame({'A': ['foo', 'bar', 'foo', 'bar',
...:                           'foo', 'bar', 'foo', 'foo'],
...:                      'B': ['one', 'one', 'two', 'three',
...:                           'two', 'two', 'one', 'three'],
...:                      'C': np.random.randn(8),
...:                      'D': np.random.randn(8)})
```

(continues on next page)

(continued from previous page)

```
In [7]: df
Out[7]:
      A        B        C        D
0  foo    one -0.628582 -0.605902
1  bar    one -0.659017 -1.232662
2  foo    two  0.006284 -0.848211
3  bar   three  0.621470 -1.774997
4  foo    two  0.863569 -1.100902
5  bar    two  1.039957 -1.129254
6  foo    one  0.190706 -0.603935
7  foo   three  0.435513 -0.534196
```

On a DataFrame, we obtain a GroupBy object by calling `groupby()`. We could naturally group by either the A or B columns, or both:

```
In [8]: grouped = df.groupby('A')
In [9]: grouped = df.groupby(['A', 'B'])
```

New in version 0.24.

If we also have a MultiIndex on columns A and B, we can group by all but the specified columns

```
In [10]: df2 = df.set_index(['A', 'B'])
In [11]: grouped = df2.groupby(level=df2.index.names.difference(['B']))
In [12]: grouped.sum()
Out[12]:
          C        D
A
bar  1.002409 -4.136913
foo  0.867490 -3.693145
```

These will split the DataFrame on its index (rows). We could also split by the columns:

```
In [13]: def get_letter_type(letter):
....:     if letter.lower() in 'aeiou':
....:         return 'vowel'
....:     else:
....:         return 'consonant'
....:

In [14]: grouped = df.groupby(get_letter_type, axis=1)
```

pandas `Index` objects support duplicate values. If a non-unique index is used as the group key in a `groupby` operation, all values for the same index value will be considered to be in one group and thus the output of aggregation functions will only contain unique index values:

```
In [15]: lst = [1, 2, 3, 1, 2, 3]
In [16]: s = pd.Series([1, 2, 3, 10, 20, 30], lst)
In [17]: grouped = s.groupby(level=0)
In [18]: grouped.first()
Out[18]:
```

(continues on next page)

(continued from previous page)

```

1    1
2    2
3    3
dtype: int64

In [19]: grouped.last()
Out[19]:
1    10
2    20
3    30
dtype: int64

In [20]: grouped.sum()
Out[20]:
1    11
2    22
3    33
dtype: int64

```

Note that **no splitting occurs** until it's needed. Creating the GroupBy object only verifies that you've passed a valid mapping.

Note: Many kinds of complicated data manipulations can be expressed in terms of GroupBy operations (though can't be guaranteed to be the most efficient). You can get quite creative with the label mapping functions.

GroupBy sorting

By default the group keys are sorted during the `groupby` operation. You may however pass `sort=False` for potential speedups:

```

In [21]: df2 = pd.DataFrame({'X': ['B', 'B', 'A', 'A'], 'Y': [1, 2, 3, 4]})

In [22]: df2.groupby(['X']).sum()
Out[22]:
Y
X
A    7
B    3

In [23]: df2.groupby(['X'], sort=False).sum()
Out[23]:
Y
X
B    3
A    7

```

Note that `groupby` will preserve the order in which *observations* are sorted *within* each group. For example, the groups created by `groupby()` below are in the order they appeared in the original DataFrame:

```

In [24]: df3 = pd.DataFrame({'X': ['A', 'B', 'A', 'B'], 'Y': [1, 4, 3, 2]})

In [25]: df3.groupby(['X']).get_group('A')
Out[25]:

```

(continues on next page)

(continued from previous page)

```
In [26]: df3.groupby(['X']).get_group('B')
Out[26]:
      X    Y
1    B    4
3    B    2
```

GroupBy object attributes

The `groups` attribute is a dict whose keys are the computed unique groups and corresponding values being the axis labels belonging to each group. In the above example we have:

```
In [27]: df.groupby('A').groups
Out[27]:
{'bar': Int64Index([1, 3, 5], dtype='int64'),
 'foo': Int64Index([0, 2, 4, 6, 7], dtype='int64')}

In [28]: df.groupby(get_letter_type, axis=1).groups
Out[28]:
{'consonant': Index(['B', 'C', 'D'], dtype='object'),
 'vowel': Index(['A'], dtype='object')}
```

Calling the standard Python `len` function on the GroupBy object just returns the length of the `groups` dict, so it is largely just a convenience:

```
In [29]: grouped = df.groupby(['A', 'B'])

In [30]: grouped.groups
Out[30]:
{('bar', 'one'): Int64Index([1], dtype='int64'),
 ('bar', 'three'): Int64Index([3], dtype='int64'),
 ('bar', 'two'): Int64Index([5], dtype='int64'),
 ('foo', 'one'): Int64Index([0, 6], dtype='int64'),
 ('foo', 'three'): Int64Index([7], dtype='int64'),
 ('foo', 'two'): Int64Index([2, 4], dtype='int64')}

In [31]: len(grouped)
Out[31]: 6
```

GroupBy will tab complete column names (and other attributes):

```
In [32]: df
Out[32]:
       height     weight   gender
2000-01-01  73.483131  142.464239    male
2000-01-02  47.026978  164.381377    male
2000-01-03  60.062603  143.433937    male
2000-01-04  74.920052  138.493882    male
2000-01-05  65.563422  190.675026  female
2000-01-06  57.652612  166.503805    male
2000-01-07  57.297587  166.916100    male
2000-01-08  61.240840  189.235339    male
```

(continues on next page)

(continued from previous page)

```

```

GroupBy with MultiIndex

With *hierarchically-indexed data*, it's quite natural to group by one of the levels of the hierarchy.

Let's create a Series with a two-level MultiIndex.

```
In [35]: arrays = [['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'],
....:             ['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two']]
....:

In [36]: index = pd.MultiIndex.from_arrays(arrays, names=['first', 'second'])

In [37]: s = pd.Series(np.random.randn(8), index=index)

In [38]: s
Out[38]:
first   second
bar     one        1.138417
        two        1.343936
baz     one        0.025089
        two        0.468956
foo     one        1.168417
        two        1.600425
qux     one        0.843743
        two       -0.486645
dtype: float64
```

We can then group by one of the levels in `s`.

```
In [39]: grouped = s.groupby(level=0)

In [40]: grouped.sum()
Out[40]:
first
bar    2.482353
baz    0.494045
foo    2.768842
qux    0.357098
dtype: float64
```

If the MultiIndex has names specified, these can be passed instead of the level number:

```
In [41]: s.groupby(level='second').sum()
Out[41]:
second
one    3.175665
two    2.926673
dtype: float64
```

The aggregation functions such as `sum` will take the level parameter directly. Additionally, the resulting index will be named according to the chosen level:

```
In [42]: s.sum(level='second')
Out[42]:
second
one    3.175665
two    2.926673
dtype: float64
```

Grouping with multiple levels is supported.

```
In [43]: s
Out[43]:
first   second   third
bar     doo      one    0.435929
          two     -0.157979
baz     bee      one    0.228013
          two     -0.907488
foo     bop      one    1.142515
          two     -0.308185
qux     bop      one   -0.761703
          two    -0.106581
dtype: float64

In [44]: s.groupby(['first', 'second']).sum()
Out[44]:
first   second
bar     doo      0.277950
baz     bee     -0.679475
foo     bop      0.834330
qux     bop     -0.868285
dtype: float64
```

Index level names may be supplied as keys.

```
In [45]: s.groupby(['first', 'second']).sum()
Out[45]:
first   second
bar     doo      0.277950
baz     bee     -0.679475
foo     bop      0.834330
qux     bop     -0.868285
dtype: float64
```

More on the `sum` function and aggregation later.

Grouping DataFrame with Index levels and columns

A DataFrame may be grouped by a combination of columns and index levels by specifying the column names as strings and the index levels as pd.Grouper objects.

```
In [46]: arrays = [['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'],
....:                 ['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two']]
....:

In [47]: index = pd.MultiIndex.from_arrays(arrays, names=['first', 'second'])

In [48]: df = pd.DataFrame({'A': [1, 1, 1, 1, 2, 2, 3, 3],
....:                         'B': np.arange(8)},
....:                         index=index)
....:

In [49]: df
Out[49]:
      A    B
first second
bar   one     1  0
      two     1  1
baz   one     1  2
      two     1  3
foo   one     2  4
      two     2  5
qux   one     3  6
      two     3  7
```

The following example groups df by the second index level and the A column.

```
In [50]: df.groupby([pd.Grouper(level=1), 'A']).sum()
Out[50]:
      B
second A
one   1  2
      2  4
      3  6
two   1  4
      2  5
      3  7
```

Index levels may also be specified by name.

```
In [51]: df.groupby([pd.Grouper(level='second'), 'A']).sum()
Out[51]:
      B
second A
one   1  2
      2  4
      3  6
two   1  4
      2  5
      3  7
```

Index level names may be specified as keys directly to groupby.

```
In [52]: df.groupby(['second', 'A']).sum()
Out[52]:
      B
second A
one    1   2
       2   4
       3   6
two    1   4
       2   5
       3   7
```

DataFrame column selection in GroupBy

Once you have created the GroupBy object from a DataFrame, you might want to do something different for each of the columns. Thus, using [] similar to getting a column from a DataFrame, you can do:

```
In [53]: grouped = df.groupby(['A'])

In [54]: grouped_C = grouped['C']

In [55]: grouped_D = grouped['D']
```

This is mainly syntactic sugar for the alternative and much more verbose:

```
In [56]: df['C'].groupby(df['A'])
Out[56]: <pandas.core.groupby.generic.SeriesGroupBy object at 0x7f6d765799d0>
```

Additionally this method avoids recomputing the internal grouping information derived from the passed key.

3.13.2 Iterating through groups

With the GroupBy object in hand, iterating through the grouped data is very natural and functions similarly to `itertools.groupby()`:

```
In [57]: grouped = df.groupby('A')

In [58]: for name, group in grouped:
....:     print(name)
....:     print(group)
....:

bar
      A      B      C      D
1 bar    one  0.191767 -0.461397
3 bar  three -1.298329  1.127451
5 bar    two  0.162568 -0.398241

foo
      A      B      C      D
0 foo    one -1.176463 -0.494005
2 foo    two -1.280508 -0.193924
4 foo    two  1.501863  0.823062
6 foo    one -2.142056 -2.330079
7 foo  three -0.133316  0.567123
```

In the case of grouping by multiple keys, the group name will be a tuple:

```
In [59]: for name, group in df.groupby(['A', 'B']):
....:     print(name)
....:     print(group)
....:
('bar', 'one')
   A      B      C      D
1  bar   one  0.191767 -0.461397
('bar', 'three')
   A      B      C      D
3  bar  three -1.298329  1.127451
('bar', 'two')
   A      B      C      D
5  bar   two  0.162568 -0.398241
('foo', 'one')
   A      B      C      D
0  foo   one -1.176463 -0.494005
6  foo   one -2.142056 -2.330079
('foo', 'three')
   A      B      C      D
7  foo  three -0.133316  0.567123
('foo', 'two')
   A      B      C      D
2  foo   two -1.280508 -0.193924
4  foo   two  1.501863  0.823062
```

See *Iterating through groups*.

3.13.3 Selecting a group

A single group can be selected using `get_group()`:

```
In [60]: grouped.get_group('bar')
Out[60]:
   A      B      C      D
1  bar   one  0.191767 -0.461397
3  bar  three -1.298329  1.127451
5  bar   two  0.162568 -0.398241
```

Or for an object grouped on multiple columns:

```
In [61]: df.groupby(['A', 'B']).get_group(('bar', 'one'))
Out[61]:
   A      B      C      D
1  bar   one  0.191767 -0.461397
```

3.13.4 Aggregation

Once the GroupBy object has been created, several methods are available to perform a computation on the grouped data. These operations are similar to the [aggregating API](#), [window functions API](#), and [resample API](#).

An obvious one is aggregation via the `aggregate()` or equivalently `agg()` method:

```
In [62]: grouped = df.groupby('A')

In [63]: grouped.aggregate(np.sum)
Out[63]:
          C          D
A
bar -0.943995  0.267814
foo -3.230481 -1.627824

In [64]: grouped = df.groupby(['A', 'B'])

In [65]: grouped.aggregate(np.sum)
Out[65]:
          C          D
A   B
bar one    0.191767 -0.461397
     three -1.298329  1.127451
     two    0.162568 -0.398241
foo one    -3.318519 -2.824085
     three -0.133316  0.567123
     two    0.221355  0.629138
```

As you can see, the result of the aggregation will have the group names as the new index along the grouped axis. In the case of multiple keys, the result is a [MultiIndex](#) by default, though this can be changed by using the `as_index` option:

```
In [66]: grouped = df.groupby(['A', 'B'], as_index=False)

In [67]: grouped.aggregate(np.sum)
Out[67]:
      A      B      C      D
0 bar   one  0.191767 -0.461397
1 bar  three -1.298329  1.127451
2 bar   two  0.162568 -0.398241
3 foo   one -3.318519 -2.824085
4 foo  three -0.133316  0.567123
5 foo   two  0.221355  0.629138

In [68]: df.groupby('A', as_index=False).sum()
Out[68]:
      A      C      D
0 bar -0.943995  0.267814
1 foo -3.230481 -1.627824
```

Note that you could use the `reset_index` DataFrame function to achieve the same result as the column names are stored in the resulting MultiIndex:

```
In [69]: df.groupby(['A', 'B']).sum().reset_index()
Out[69]:
      A      B      C      D
0 bar   one  0.191767 -0.461397
```

(continues on next page)

(continued from previous page)

```
1 bar three -1.298329 1.127451
2 bar two 0.162568 -0.398241
3 foo one -3.318519 -2.824085
4 foo three -0.133316 0.567123
5 foo two 0.221355 0.629138
```

Another simple aggregation example is to compute the size of each group. This is included in GroupBy as the `size` method. It returns a Series whose index are the group names and whose values are the sizes of each group.

In [70]: `grouped.size()`

Out[70]:

```
A    B
bar one    1
      three   1
      two    1
foo one    2
      three   1
      two    2
dtype: int64
```

In [71]: `grouped.describe()`

Out[71]:

	C	D
count	1.0	1.0

Note: Aggregation functions **will not** return the groups that you are aggregating over if they are named `columns`, when `as_index=True`, the default. The grouped columns will be the `indices` of the returned object.

Passing `as_index=False` **will** return the groups that you are aggregating over, if they are named `columns`.

Aggregating functions are the ones that reduce the dimension of the returned objects. Some common aggregating functions are tabulated below:

Function	Description
mean()	Compute mean of groups
sum()	Compute sum of group values
size()	Compute group sizes
count()	Compute count of group
std()	Standard deviation of groups
var()	Compute variance of groups
sem()	Standard error of the mean of groups
describe()	Generates descriptive statistics
first()	Compute first of group values
last()	Compute last of group values
nth()	Take nth value, or a subset if n is a list
min()	Compute min of group values
max()	Compute max of group values

The aggregating functions above will exclude NA values. Any function which reduces a Series to a scalar value is an aggregation function and will work, a trivial example is `df.groupby('A').agg(lambda ser: 1)`. Note that `nth()` can act as a reducer *or* a filter, see [here](#).

Applying multiple functions at once

With grouped Series you can also pass a list or dict of functions to do aggregation with, outputting a DataFrame:

```
In [72]: grouped = df.groupby('A')

In [73]: grouped['C'].agg([np.sum, np.mean, np.std])
Out[73]:
          sum      mean      std
A
bar -0.943995 -0.314665  0.852003
foo -3.230481 -0.646096  1.396275
```

On a grouped DataFrame, you can pass a list of functions to apply to each column, which produces an aggregated result with a hierarchical index:

```
In [74]: grouped.agg([np.sum, np.mean, np.std])
Out[74]:
          C                               D
          sum      mean      std      sum      mean      std
A
bar -0.943995 -0.314665  0.852003  0.267814  0.089271  0.899644
foo -3.230481 -0.646096  1.396275 -1.627824 -0.325565  1.242982
```

The resulting aggregations are named for the functions themselves. If you need to rename, then you can add in a chained operation for a Series like this:

```
In [75]: (grouped['C'].agg([np.sum, np.mean, np.std])
.....           .rename(columns={'sum': 'foo',
.....                           'mean': 'bar',
.....                           'std': 'baz'}))

Out[75]:
          foo      bar      baz
A
```

(continues on next page)

(continued from previous page)

```
bar -0.943995 -0.314665 0.852003
foo -3.230481 -0.646096 1.396275
```

For a grouped DataFrame, you can rename in a similar manner:

```
In [76]: (grouped.agg([np.sum, np.mean, np.std])
.....      .rename(columns={'sum': 'foo',
.....                      'mean': 'bar',
.....                      'std': 'baz'}))
.....
Out[76]:
          C                               D
          foo      bar      baz      foo      bar      baz
A
bar -0.943995 -0.314665 0.852003 0.267814 0.089271 0.899644
foo -3.230481 -0.646096 1.396275 -1.627824 -0.325565 1.242982
```

Note: In general, the output column names should be unique. You can't apply the same function (or two functions with the same name) to the same column.

```
In [77]: grouped['C'].agg(['sum', 'sum'])
Out[77]:
          sum      sum
A
bar -0.943995 -0.943995
foo -3.230481 -3.230481
```

Pandas *does* allow you to provide multiple lambdas. In this case, pandas will mangle the name of the (nameless) lambda functions, appending _<i> to each subsequent lambda.

```
In [78]: grouped['C'].agg([lambda x: x.max() - x.min(),
.....                  lambda x: x.median() - x.mean()])
.....
Out[78]:
<lambda_0> <lambda_1>
A
bar    1.490096   0.477233
foo    3.643919  -0.530367
```

Named aggregation

New in version 0.25.0.

To support column-specific aggregation *with control over the output column names*, pandas accepts the special syntax in GroupBy.agg(), known as “named aggregation”, where

- The keywords are the *output* column names
- The values are tuples whose first element is the column to select and the second element is the aggregation to apply to that column. Pandas provides the pandas.NamedAgg namedtuple with the fields ['column', 'aggfunc'] to make it clearer what the arguments are. As usual, the aggregation can be a callable or a string alias.

```
In [79]: animals = pd.DataFrame({'kind': ['cat', 'dog', 'cat', 'dog'],
.....:                           'height': [9.1, 6.0, 9.5, 34.0],
.....:                           'weight': [7.9, 7.5, 9.9, 198.0]})

In [80]: animals
Out[80]:
   kind  height  weight
0  cat      9.1     7.9
1  dog      6.0     7.5
2  cat      9.5     9.9
3  dog     34.0    198.0

In [81]: animals.groupby("kind").agg(
.....:     min_height=pd.NamedAgg(column='height', aggfunc='min'),
.....:     max_height=pd.NamedAgg(column='height', aggfunc='max'),
.....:     average_weight=pd.NamedAgg(column='weight', aggfunc=np.mean),
.....: )
.....:

Out[81]:
      min_height  max_height  average_weight
kind
cat            9.1          9.5           8.90
dog            6.0         34.0          102.75
```

`pandas.NamedAgg` is just a namedtuple. Plain tuples are allowed as well.

```
In [82]: animals.groupby("kind").agg(
.....:     min_height=('height', 'min'),
.....:     max_height=('height', 'max'),
.....:     average_weight=('weight', np.mean),
.....: )
.....:

Out[82]:
      min_height  max_height  average_weight
kind
cat            9.1          9.5           8.90
dog            6.0         34.0          102.75
```

If your desired output column names are not valid python keywords, construct a dictionary and unpack the keyword arguments

```
In [83]: animals.groupby("kind").agg(**{
.....:     'total_weight': pd.NamedAgg(column='weight', aggfunc=sum),
.....: })
.....:

Out[83]:
      total_weight
kind
cat            17.8
dog          205.5
```

Additional keyword arguments are not passed through to the aggregation functions. Only pairs of `(column, aggfunc)` should be passed as `**kwargs`. If your aggregation functions requires additional arguments, partially apply them with `functools.partial()`.

Note: For Python 3.5 and earlier, the order of `**kwargs` in a functions was not preserved. This means that the

output column ordering would not be consistent. To ensure consistent ordering, the keys (and so output columns) will always be sorted for Python 3.5.

Named aggregation is also valid for Series groupby aggregations. In this case there's no column selection, so the values are just the functions.

```
In [84]: animals.groupby("kind").height.agg(  
....:     min_height='min',  
....:     max_height='max',  
....: )  
....:  
Out[84]:  
      min_height  max_height  
kind  
cat           9.1          9.5  
dog           6.0         34.0
```

Applying different functions to DataFrame columns

By passing a dict to aggregate you can apply a different aggregation to the columns of a DataFrame:

```
In [85]: grouped.agg({'C': np.sum,  
....:                   'D': lambda x: np.std(x, ddof=1)})  
....:  
Out[85]:  
      C          D  
A  
bar -0.943995  0.899644  
foo -3.230481  1.242982
```

The function names can also be strings. In order for a string to be valid it must be either implemented on GroupBy or available via *dispatching*:

```
In [86]: grouped.agg({'C': 'sum', 'D': 'std'})  
Out[86]:  
      C          D  
A  
bar -0.943995  0.899644  
foo -3.230481  1.242982
```

Cython-optimized aggregation functions

Some common aggregations, currently only sum, mean, std, and sem, have optimized Cython implementations:

```
In [87]: df.groupby('A').sum()  
Out[87]:  
      C          D  
A  
bar -0.943995  0.267814  
foo -3.230481 -1.627824  
  
In [88]: df.groupby(['A', 'B']).mean()  
Out[88]:  
      C          D
```

(continues on next page)

(continued from previous page)

```
A    B
bar one    0.191767 -0.461397
      three -1.298329  1.127451
      two    0.162568 -0.398241
foo one    -1.659260 -1.412042
      three -0.133316  0.567123
      two    0.110677  0.314569
```

Of course `sum` and `mean` are implemented on pandas objects, so the above code would work even without the special versions via dispatching (see below).

3.13.5 Transformation

The `transform` method returns an object that is indexed the same (same size) as the one being grouped. The `transform` function must:

- Return a result that is either the same size as the group chunk or broadcastable to the size of the group chunk (e.g., a scalar, `grouped.transform(lambda x: x.iloc[-1])`).
- Operate column-by-column on the group chunk. The transform is applied to the first group chunk using `chunk.apply`.
- Not perform in-place operations on the group chunk. Group chunks should be treated as immutable, and changes to a group chunk may produce unexpected results. For example, when using `fillna`, `inplace` must be `False` (`grouped.transform(lambda x: x.fillna(inplace=False))`).
- (Optionally) operates on the entire group chunk. If this is supported, a fast path is used starting from the *second* chunk.

For example, suppose we wished to standardize the data within each group:

```
In [89]: index = pd.date_range('10/1/1999', periods=1100)

In [90]: ts = pd.Series(np.random.normal(0.5, 2, 1100), index)

In [91]: ts = ts.rolling(window=100, min_periods=100).mean().dropna()

In [92]: ts.head()
Out[92]:
2000-01-08    0.314824
2000-01-09    0.329200
2000-01-10    0.353204
2000-01-11    0.371593
2000-01-12    0.416766
Freq: D, dtype: float64

In [93]: ts.tail()
Out[93]:
2002-09-30    0.366469
2002-10-01    0.356543
2002-10-02    0.395449
2002-10-03    0.402781
2002-10-04    0.428122
Freq: D, dtype: float64

In [94]: transformed = (ts.groupby(lambda x: x.year)
```

(continues on next page)

(continued from previous page)

```
....:         .transform(lambda x: (x - x.mean()) / x.std())
....:
```

We would expect the result to now have mean 0 and standard deviation 1 within each group, which we can easily check:

```
# Original Data
In [95]: grouped = ts.groupby(lambda x: x.year)

In [96]: grouped.mean()
Out[96]:
2000    0.410178
2001    0.504012
2002    0.589739
dtype: float64

In [97]: grouped.std()
Out[97]:
2000    0.155028
2001    0.242843
2002    0.243006
dtype: float64

# Transformed Data
In [98]: grouped_trans = transformed.groupby(lambda x: x.year)

In [99]: grouped_trans.mean()
Out[99]:
2000   -1.447310e-15
2001    3.141475e-15
2002   -1.278560e-16
dtype: float64

In [100]: grouped_trans.std()
Out[100]:
2000    1.0
2001    1.0
2002    1.0
dtype: float64
```

We can also visually compare the original and transformed data sets.

```
In [101]: compare = pd.DataFrame({'Original': ts, 'Transformed': transformed})

In [102]: compare.plot()
Out[102]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d750f5bd0>
```

Transformation functions that have lower dimension outputs are broadcast to match the shape of the input array.

```
In [103]: ts.groupby(lambda x: x.year).transform(lambda x: x.max() - x.min())
Out[103]:
2000-01-08    0.781948
2000-01-09    0.781948
2000-01-10    0.781948
2000-01-11    0.781948
2000-01-12    0.781948
...
2002-09-30    0.936875
2002-10-01    0.936875
2002-10-02    0.936875
2002-10-03    0.936875
2002-10-04    0.936875
Freq: D, Length: 1001, dtype: float64
```

Alternatively, the built-in methods could be used to produce the same outputs.

```
In [104]: max = ts.groupby(lambda x: x.year).transform('max')
In [105]: min = ts.groupby(lambda x: x.year).transform('min')
In [106]: max - min
Out[106]:
```

(continues on next page)

(continued from previous page)

```
2000-01-08    0.781948
2000-01-09    0.781948
2000-01-10    0.781948
2000-01-11    0.781948
2000-01-12    0.781948
...
2002-09-30    0.936875
2002-10-01    0.936875
2002-10-02    0.936875
2002-10-03    0.936875
2002-10-04    0.936875
Freq: D, Length: 1001, dtype: float64
```

Another common data transform is to replace missing data with the group mean.

```
In [107]: data_df
Out[107]:
      A         B         C
0 -0.760560 -1.485870  1.233792

dtype: int64
```

Note: Some functions will automatically transform the input when applied to a GroupBy object, but returning an object of the same shape as the original. Passing `as_index=False` will not affect these transformation methods.

For example: `fillna`, `ffill`, `bfill`, `shift`..

In [119]: grouped.ffill()

Out[119]:

```
A      B      C
0   -0.760560 -1.485870  1.233792
1   -1.125968  0.147243  0.216862
2   -1.125968  0.730341  1.137739
3   -0.687453 -2.203337 -0.055434
4       NaN   -0.543932  1.198175

```

```
[1000 rows x 3 columns]
```

Window and resample operations

It is possible to use `resample()`, `expanding()` and `rolling()` as methods on groupbys.

The example below will apply the `rolling()` method on the samples of the column B based on the groups of column A.

```
In [120]: df_re = pd.DataFrame({'A': [1] * 10 + [5] * 10,
.....:                      'B': np.arange(20)})

.....:
```

```
In [121]: df_re
```

```
Out[121]:
```

```
   A    B
0  1    0
1  1    1
2  1    2
3  1    3
4  1    4
5  1    5
6  1    6
7  1    7
8  1    8
9  1    9
10 5   10
11 5   11
12 5   12
13 5   13
14 5   14
15 5   15
16 5   16
17 5   17
18 5   18
19 5   19
```

```
In [122]: df_re.groupby('A').rolling(4).B.mean()
```

```
Out[122]:
```

```
A
1  0      NaN
    1      NaN
    2      NaN
    3      1.5
    4      2.5
    5      3.5
    6      4.5
    7      5.5
    8      6.5
    9      7.5
5  10     NaN
    11     NaN
```

(continues on next page)

(continued from previous page)

```

12      NaN
13    11.5
14    12.5
15    13.5
16    14.5
17    15.5
18    16.5
19    17.5
Name: B, dtype: float64

```

The `expanding()` method will accumulate a given operation (`sum()` in the example) for all the members of each particular group.

```
In [123]: df_re.groupby('A').expanding().sum()
```

```
Out[123]:
```

	A	B
A		
1 0	1.0	0.0
1 1	2.0	1.0
2 2	3.0	3.0
3 3	4.0	6.0
4 4	5.0	10.0
5 5	6.0	15.0
6 6	7.0	21.0
7 7	8.0	28.0
8 8	9.0	36.0
9 9	10.0	45.0
5 10	5.0	10.0
11 11	10.0	21.0
12 12	15.0	33.0
13 13	20.0	46.0
14 14	25.0	60.0
15 15	30.0	75.0
16 16	35.0	91.0
17 17	40.0	108.0
18 18	45.0	126.0
19 19	50.0	145.0

Suppose you want to use the `resample()` method to get a daily frequency in each group of your dataframe and wish to complete the missing values with the `ffill()` method.

```
In [124]: df_re = pd.DataFrame({'date': pd.date_range(start='2016-01-01', periods=4,
.....:                               freq='W'),
.....:                               'group': [1, 1, 2, 2],
.....:                               'val': [5, 6, 7, 8]}) .set_index('date')
.....:
```

```
In [125]: df_re
```

```
Out[125]:
```

date	group	val
2016-01-03	1	5
2016-01-10	1	6
2016-01-17	2	7
2016-01-24	2	8

(continues on next page)

(continued from previous page)

```
In [126]: df_re.groupby('group').resample('1D').ffill()  
Out[126]:
```

group	date	group	val
1	2016-01-03	1	5
	2016-01-04	1	5
	2016-01-05	1	5
	2016-01-06	1	5
	2016-01-07	1	5
	2016-01-08	1	5
	2016-01-09	1	5
	2016-01-10	1	6
2	2016-01-17	2	7
	2016-01-18	2	7
	2016-01-19	2	7
	2016-01-20	2	7
	2016-01-21	2	7
	2016-01-22	2	7
	2016-01-23	2	7
	2016-01-24	2	8

3.13.6 Filtration

The `filter` method returns a subset of the original object. Suppose we want to take only elements that belong to groups with a group sum greater than 2.

```
In [127]: sf = pd.Series([1, 1, 2, 3, 3, 3])  
  
In [128]: sf.groupby(sf).filter(lambda x: x.sum() > 2)  
Out[128]:
```

3	3
4	3
5	3

dtype: int64

The argument of `filter` must be a function that, applied to the group as a whole, returns `True` or `False`.

Another useful operation is filtering out elements that belong to groups with only a couple members.

```
In [129]: dff = pd.DataFrame({'A': np.arange(8), 'B': list('aabbbbcc')})  
  
In [130]: dff.groupby('B').filter(lambda x: len(x) > 2)  
Out[130]:
```

A	B
2	b
3	b
4	b
5	b

Alternatively, instead of dropping the offending groups, we can return a like-indexed objects where the groups that do not pass the filter are filled with `NaNs`.

```
In [131]: dff.groupby('B').filter(lambda x: len(x) > 2, dropna=False)  
Out[131]:
```

A	B
2	b
3	b
4	b
5	b

(continues on next page)

(continued from previous page)

0	NaN	NaN
1	NaN	NaN
2	2.0	b
3	3.0	b
4	4.0	b
5	5.0	b
6	NaN	NaN
7	NaN	NaN

For DataFrames with multiple columns, filters should explicitly specify a column as the filter criterion.

In [132]:	dff['C'] = np.arange(8)
In [133]:	dff.groupby('B').filter(lambda x: len(x['C']) > 2)
Out[133]:	A B C 2 2 b 2 3 3 b 3 4 4 b 4 5 5 b 5

Note: Some functions when applied to a groupby object will act as a **filter** on the input, returning a reduced shape of the original (and potentially eliminating groups), but with the index unchanged. Passing `as_index=False` will not affect these transformation methods.

For example: `head`, `tail`.

In [134]:	dff.groupby('B').head(2)
Out[134]:	A B C 0 0 a 0 1 1 a 1 2 2 b 2 3 3 b 3 6 6 c 6 7 7 c 7

3.13.7 Dispatching to instance methods

When doing an aggregation or transformation, you might just want to call an instance method on each data group. This is pretty easy to do by passing lambda functions:

In [135]:	grouped = df.groupby('A')
In [136]:	grouped.agg(lambda x: x.std())
Out[136]:	C D A bar 0.852003 0.899644 foo 1.396275 1.242982

But, it's rather verbose and can be untidy if you need to pass additional arguments. Using a bit of metaprogramming cleverness, GroupBy now has the ability to "dispatch" method calls to the groups:

```
In [137]: grouped.std()
Out[137]:
          C          D
A
bar  0.852003  0.899644
foo  1.396275  1.242982
```

What is actually happening here is that a function wrapper is being generated. When invoked, it takes any passed arguments and invokes the function with any arguments on each group (in the above example, the `std` function). The results are then combined together much in the style of `agg` and `transform` (it actually uses `apply` to infer the gluing, documented next). This enables some operations to be carried out rather succinctly:

```
In [138]: tsdf = pd.DataFrame(np.random.randn(1000, 3),
.....:                               index=pd.date_range('1/1/2000', periods=1000),
.....:                               columns=['A', 'B', 'C'])
.....:

In [139]: tsdf.iloc[:,::2] = np.nan

In [140]: grouped = tsdf.groupby(lambda x: x.year)

In [141]: grouped.fillna(method='pad')
Out[141]:
          A          B          C
2000-01-01    NaN      NaN      NaN
2000-01-02  0.827238 -0.887927 -0.289847
2000-01-03  0.827238 -0.887927 -0.289847
2000-01-04  0.870678  2.375174 -1.359889
2000-01-05  0.870678  2.375174 -1.359889
...
...
2002-09-22  0.449918 -1.150571 -0.619332
2002-09-23  0.449918 -1.150571 -0.619332
2002-09-24  0.958056  1.228164  0.631950
2002-09-25  0.958056  1.228164  0.631950
2002-09-26  0.411362 -0.175993  0.109578

[1000 rows x 3 columns]
```

In this example, we chopped the collection of time series into yearly chunks then independently called `fillna` on the groups.

The `nlargest` and `nsmallest` methods work on Series style groupbys:

```
In [142]: s = pd.Series([9, 8, 7, 5, 19, 1, 4.2, 3.3])

In [143]: g = pd.Series(list('abababab'))

In [144]: gb = s.groupby(g)

In [145]: gb.nlargest(3)
Out[145]:
a    4    19.0
      0    9.0
      2    7.0
b    1    8.0
      3    5.0
      7    3.3
```

(continues on next page)

(continued from previous page)

```
dtype: float64
```

In [146]: gb.nsmallest(3)
Out[146]:

	a	b	c	d
0	6	5	7	3
1	2	7	3.3	5.0
2	0	3	1.0	9.0

```
dtype: float64
```

3.13.8 Flexible apply

Some operations on the grouped data might not fit into either the aggregate or transform categories. Or, you may simply want GroupBy to infer how to combine the results. For these, use the `apply` function, which can be substituted for both `aggregate` and `transform` in many standard use cases. However, `apply` can handle some exceptional use cases, for example:

```
In [147]: df
Out[147]:
      A        B        C        D
0  foo    one -1.176463 -0.494005
1  bar    one  0.191767 -0.461397
2  foo    two -1.280508 -0.193924
3  bar   three -1.298329  1.127451
4  foo    two  1.501863  0.823062
5  bar    two  0.162568 -0.398241
6  foo    one -2.142056 -2.330079
7  foo   three -0.133316  0.567123

In [148]: grouped = df.groupby('A')

# could also just call .describe()
In [149]: grouped['C'].apply(lambda x: x.describe())
Out[149]:
A
bar  count    3.000000
      mean    -0.314665
      std     0.852003
      min    -1.298329
      25%    -0.567881
      50%    0.162568
      75%    0.177167
      max     0.191767
foo  count    5.000000
      mean    -0.646096
      std     1.396275
      min    -2.142056
      25%    -1.280508
      50%    -1.176463
      75%    -0.133316
      max     1.501863
Name: C, dtype: float64
```

The dimension of the returned result can also change:

```
In [150]: grouped = df.groupby('A')[['C']]  
  
In [151]: def f(group):  
.....:     return pd.DataFrame({'original': group,  
.....:                           'demeaned': group - group.mean() })  
.....:  
  
In [152]: grouped.apply(f)  
Out[152]:  
    original   demeaned  
0 -1.176463 -0.530367  
1  0.191767  0.506432  
2 -1.280508 -0.634412  
3 -1.298329 -0.983664  
4  1.501863  2.147959  
5  0.162568  0.477233  
6 -2.142056 -1.495960  
7 -0.133316  0.512780
```

apply on a Series can operate on a returned value from the applied function, that is itself a series, and possibly upcast the result to a DataFrame:

```
In [153]: def f(x):  
.....:     return pd.Series([x, x ** 2], index=['x', 'x^2'])  
.....:  
  
In [154]: s = pd.Series(np.random.rand(5))  
  
In [155]: s  
Out[155]:  
0    0.020509  
1    0.588155  
2    0.712242  
3    0.308572  
4    0.108911  
dtype: float64  
  
In [156]: s.apply(f)  
Out[156]:  
      x      x^2  
0  0.020509  0.000421  
1  0.588155  0.345926  
2  0.712242  0.507289  
3  0.308572  0.095217  
4  0.108911  0.011862
```

Note: apply can act as a reducer, transformer, or filter function, depending on exactly what is passed to it. So depending on the path taken, and exactly what you are grouping. Thus the grouped columns(s) may be included in the output as well as set the indices.

3.13.9 Other useful features

Automatic exclusion of “nuisance” columns

Again consider the example DataFrame we’ve been looking at:

```
In [157]: df
Out[157]:
   A      B      C      D
0  foo    one -1.176463 -0.494005
1  bar    one  0.191767 -0.461397
2  foo    two -1.280508 -0.193924
3  bar  three -1.298329  1.127451
4  foo    two  1.501863  0.823062
5  bar    two  0.162568 -0.398241
6  foo    one -2.142056 -2.330079
7  foo  three -0.133316  0.567123
```

Suppose we wish to compute the standard deviation grouped by the A column. There is a slight problem, namely that we don’t care about the data in column B. We refer to this as a “nuisance” column. If the passed aggregation function can’t be applied to some columns, the troublesome columns will be (silently) dropped. Thus, this does not pose any problems:

```
In [158]: df.groupby('A').std()
Out[158]:
          C      D
A
bar  0.852003  0.899644
foo  1.396275  1.242982
```

Note that `df.groupby('A').colname.std()` is more efficient than `df.groupby('A').std().colname`, so if the result of an aggregation function is only interesting over one column (here `colname`), it may be filtered *before* applying the aggregation function.

Note: Any object column, also if it contains numerical values such as `Decimal` objects, is considered as a “nuisance” columns. They are excluded from aggregate functions automatically in `groupby`.

If you do wish to include decimal or object columns in an aggregation with other non-nuisance data types, you must do so explicitly.

```
In [159]: from decimal import Decimal
In [160]: df_dec = pd.DataFrame(
.....:     {'id': [1, 2, 1, 2],
.....:      'int_column': [1, 2, 3, 4],
.....:      'dec_column': [Decimal('0.50'), Decimal('0.15'),
.....:                      Decimal('0.25'), Decimal('0.40')]}
.....:     }
.....:

# Decimal columns can be sum'd explicitly by themselves...
In [161]: df_dec.groupby(['id'])[['dec_column']].sum()
Out[161]:
dec_column
```

(continues on next page)

(continued from previous page)

```
id
1      0.75
2      0.55

# ...but cannot be combined with standard data types or they will be excluded
In [162]: df_dec.groupby(['id'])[['int_column', 'dec_column']].sum()
Out[162]:
    int_column
id
1            4
2            6

# Use .agg function to aggregate over standard and "nuisance" data types
# at the same time
In [163]: df_dec.groupby(['id']).agg({'int_column': 'sum', 'dec_column': 'sum'})
Out[163]:
    int_column  dec_column
id
1            4        0.75
2            6        0.55
```

Handling of (un)observed Categorical values

When using a Categorical grouper (as a single grouper, or as part of multiple groupers), the `observed` keyword controls whether to return a cartesian product of all possible groupers values (`observed=False`) or only those that are observed groupers (`observed=True`).

Show all values:

```
In [164]: pd.Series([1, 1, 1]).groupby(pd.Categorical(['a', 'a', 'a'],
.....:                                         categories=['a', 'b']),
.....:                                         observed=False).count()
Out[164]:
a    3
b    0
dtype: int64
```

Show only the observed values:

```
In [165]: pd.Series([1, 1, 1]).groupby(pd.Categorical(['a', 'a', 'a'],
.....:                                         categories=['a', 'b']),
.....:                                         observed=True).count()
Out[165]:
a    3
dtype: int64
```

The returned `dtype` of the grouped will *always* include *all* of the categories that were grouped.

```
In [166]: s = pd.Series([1, 1, 1]).groupby(pd.Categorical(['a', 'a', 'a'],
.....:                                         categories=['a', 'b']),
.....:                                         observed=False).count()
.....:
```

(continues on next page)

(continued from previous page)

```
In [167]: s.index.dtype
Out[167]: CategoricalDtype(categories=['a', 'b'], ordered=False)
```

NA and NaT group handling

If there are any NaN or NaT values in the grouping key, these will be automatically excluded. In other words, there will never be an “NA group” or “NaT group”. This was not the case in older versions of pandas, but users were generally discarding the NA group anyway (and supporting it was an implementation headache).

Grouping with ordered factors

Categorical variables represented as instance of pandas’s `Categorical` class can be used as group keys. If so, the order of the levels will be preserved:

```
In [168]: data = pd.Series(np.random.randn(100))

In [169]: factor = pd.qcut(data, [0, .25, .5, .75, 1.])

In [170]: data.groupby(factor).mean()
Out[170]:
(-2.787, -0.827]    -1.400370
(-0.827, 0.049]     -0.331241
(0.049, 0.765]      0.372315
(0.765, 2.439]      1.176481
dtype: float64
```

Grouping with a grouper specification

You may need to specify a bit more data to properly group. You can use the `pd.Grouper` to provide this local control.

```
In [171]: import datetime

In [172]: df = pd.DataFrame({'Branch': 'A A A A A A A B'.split(),
.....:                   'Buyer': 'Carl Mark Carl Carl Joe Joe Joe Carl'.split(),
.....:                   'Quantity': [1, 3, 5, 1, 8, 1, 9, 3],
.....:                   'Date': [
.....:                       datetime.datetime(2013, 1, 1, 13, 0),
.....:                       datetime.datetime(2013, 1, 1, 13, 5),
.....:                       datetime.datetime(2013, 10, 1, 20, 0),
.....:                       datetime.datetime(2013, 10, 2, 10, 0),
.....:                       datetime.datetime(2013, 10, 1, 20, 0),
.....:                       datetime.datetime(2013, 10, 2, 10, 0),
.....:                       datetime.datetime(2013, 12, 2, 12, 0),
.....:                       datetime.datetime(2013, 12, 2, 14, 0)])
.....:                   })

In [173]: df
Out[173]:
   Branch Buyer  Quantity           Date
0       A   Carl        1 2013-01-01 13:00:00
```

(continues on next page)

(continued from previous page)

1	A	Mark	3	2013-01-01	13:05:00
2	A	Carl	5	2013-10-01	20:00:00
3	A	Carl	1	2013-10-02	10:00:00
4	A	Joe	8	2013-10-01	20:00:00
5	A	Joe	1	2013-10-02	10:00:00
6	A	Joe	9	2013-12-02	12:00:00
7	B	Carl	3	2013-12-02	14:00:00

Groupby a specific column with the desired frequency. This is like resampling.

```
In [174]: df.groupby([pd.Grouper(freq='1M', key='Date'), 'Buyer']).sum()
Out[174]:
```

Quantity		
Date	Buyer	
2013-01-31	Carl	1
	Mark	3
2013-10-31	Carl	6
	Joe	9
2013-12-31	Carl	3
	Joe	9

You have an ambiguous specification in that you have a named index and a column that could be potential groupers.

```
In [175]: df = df.set_index('Date')
```

```
In [176]: df['Date'] = df.index + pd.offsets.MonthEnd(2)
```

```
In [177]: df.groupby([pd.Grouper(freq='6M', key='Date'), 'Buyer']).sum()
Out[177]:
```

Quantity		
Date	Buyer	
2013-02-28	Carl	1
	Mark	3
2014-02-28	Carl	9
	Joe	18

```
In [178]: df.groupby([pd.Grouper(freq='6M', level='Date'), 'Buyer']).sum()
```

```
Out[178]:
```

Quantity		
Date	Buyer	
2013-01-31	Carl	1
	Mark	3
2014-01-31	Carl	9
	Joe	18

Taking the first rows of each group

Just like for a DataFrame or Series you can call head and tail on a groupby:

```
In [179]: df = pd.DataFrame([[1, 2], [1, 4], [5, 6]], columns=['A', 'B'])
```

```
In [180]: df
```

```
Out[180]:
```

A	B
0	1 2

(continues on next page)

(continued from previous page)

```

1 1 4
2 5 6

In [181]: g = df.groupby('A')

In [182]: g.head(1)
Out[182]:
   A   B
0 1 2
2 5 6

In [183]: g.tail(1)
Out[183]:
   A   B
1 1 4
2 5 6

```

This shows the first or last n rows from each group.

Taking the nth row of each group

To select from a DataFrame or Series the nth item, use `nth()`. This is a reduction method, and will return a single row (or no row) per group if you pass an int for n:

```

In [184]: df = pd.DataFrame([[1, np.nan], [1, 4], [5, 6]], columns=['A', 'B'])

In [185]: g = df.groupby('A')

In [186]: g.nth(0)
Out[186]:
   B
A
1  NaN
5  6.0

In [187]: g.nth(-1)
Out[187]:
   B
A
1  4.0
5  6.0

In [188]: g.nth(1)
Out[188]:
   B
A
1  4.0

```

If you want to select the nth not-null item, use the `dropna` kwarg. For a DataFrame this should be either 'any' or 'all' just like you would pass to `dropna`:

```

# nth(0) is the same as g.first()
In [189]: g.nth(0, dropna='any')
Out[189]:
   B

```

(continues on next page)

(continued from previous page)

```
A
1 4.0
5 6.0

In [190]: g.first()
Out[190]:
B
A
1 4.0
5 6.0

# nth(-1) is the same as g.last()
In [191]: g.nth(-1, dropna='any') # NaNs denote group exhausted when using dropna
Out[191]:
B
A
1 4.0
5 6.0

In [192]: g.last()
Out[192]:
B
A
1 4.0
5 6.0

In [193]: g.B.nth(0, dropna='all')
Out[193]:
A
1    4.0
5    6.0
Name: B, dtype: float64
```

As with other methods, passing `as_index=False`, will achieve a filtration, which returns the grouped row.

```
In [194]: df = pd.DataFrame([[1, np.nan], [1, 4], [5, 6]], columns=['A', 'B'])

In [195]: g = df.groupby('A', as_index=False)

In [196]: g.nth(0)
Out[196]:
   A    B
0  1  NaN
2  5  6.0

In [197]: g.nth(-1)
Out[197]:
   A    B
1  1  4.0
2  5  6.0
```

You can also select multiple rows from each group by specifying multiple nth values as a list of ints.

```
In [198]: business_dates = pd.date_range(start='4/1/2014', end='6/30/2014', freq='B')

In [199]: df = pd.DataFrame(1, index=business_dates, columns=['a', 'b'])
```

(continues on next page)

(continued from previous page)

```
# get the first, 4th, and last date index for each month
In [200]: df.groupby([df.index.year, df.index.month]).nth([0, 3, -1])
Out[200]:
   a   b
2014 4   1   1
      4   1   1
      4   1   1
      5   1   1
      5   1   1
      5   1   1
      6   1   1
      6   1   1
      6   1   1
```

Enumerate group items

To see the order in which each row appears within its group, use the `cumcount` method:

```
In [201]: dfg = pd.DataFrame(list('aaabba'), columns=['A'])

In [202]: dfg
Out[202]:
   A
0  a
1  a
2  a
3  b
4  b
5  a

In [203]: dfg.groupby('A').cumcount()
Out[203]:
0    0
1    1
2    2
3    0
4    1
5    3
dtype: int64

In [204]: dfg.groupby('A').cumcount(ascending=False)
Out[204]:
0    3
1    2
2    1
3    1
4    0
5    0
dtype: int64
```

Enumerate groups

To see the ordering of the groups (as opposed to the order of rows within a group given by `cumcount`) you can use `ngroup()`.

Note that the numbers given to the groups match the order in which the groups would be seen when iterating over the `groupby` object, not the order they are first observed.

```
In [205]: dfg = pd.DataFrame(list('aaabba'), columns=['A'])
```

```
In [206]: dfg
```

```
Out[206]:
```

```
   A  
0  a  
1  a  
2  a  
3  b  
4  b  
5  a
```

```
In [207]: dfg.groupby('A').ngroup()
```

```
Out[207]:
```

```
0    0  
1    0  
2    0  
3    1  
4    1  
5    0  
dtype: int64
```

```
In [208]: dfg.groupby('A').ngroup(ascending=False)
```

```
Out[208]:
```

```
0    1  
1    1  
2    1  
3    0  
4    0  
5    1  
dtype: int64
```

Plotting

Groupby also works with some plotting methods. For example, suppose we suspect that some features in a DataFrame may differ by group, in this case, the values in column 1 where the group is “B” are 3 higher on average.

```
In [209]: np.random.seed(1234)
```

```
In [210]: df = pd.DataFrame(np.random.randn(50, 2))
```

```
In [211]: df['g'] = np.random.choice(['A', 'B'], size=50)
```

```
In [212]: df.loc[df['g'] == 'B', 1] += 3
```

We can easily visualize this with a boxplot:

```
In [213]: df.groupby('g').boxplot()
Out[213]:
A      AxesSubplot(0.1,0.15;0.363636x0.75)
B      AxesSubplot(0.536364,0.15;0.363636x0.75)
dtype: object
```

The result of calling `boxplot` is a dictionary whose keys are the values of our grouping column `g` ("A" and "B"). The values of the resulting dictionary can be controlled by the `return_type` keyword of `boxplot`. See the [visualization documentation](#) for more.

Warning: For historical reasons, `df.groupby("g").boxplot()` is not equivalent to `df.boxplot(by="g")`. See [here](#) for an explanation.

Piping function calls

New in version 0.21.0.

Similar to the functionality provided by `DataFrame` and `Series`, functions that take `GroupBy` objects can be chained together using a `pipe` method to allow for a cleaner, more readable syntax. To read about `.pipe` in general terms, see [here](#).

Combining `.groupby` and `.pipe` is often useful when you need to reuse `GroupBy` objects.

As an example, imagine having a `DataFrame` with columns for stores, products, revenue and quantity sold. We'd like to do a groupwise calculation of *prices* (i.e. revenue/quantity) per store and per product. We could do this in a multi-step operation, but expressing it in terms of piping can make the code more readable. First we set the data:

```
In [214]: n = 1000

In [215]: df = pd.DataFrame({'Store': np.random.choice(['Store_1', 'Store_2'], n),
   .....:                 'Product': np.random.choice(['Product_1',
   .....:                                         'Product_2'], n),
   .....:                 'Revenue': (np.random.random(n) * 50 + 10).round(2),
   .....:                 'Quantity': np.random.randint(1, 10, size=n)})
   ......

In [216]: df.head(2)
Out[216]:
   Store    Product  Revenue  Quantity
0  Store_2  Product_1    26.12        1
1  Store_2  Product_1    28.86        1
```

Now, to find prices per store/product, we can simply do:

```
In [217]: (df.groupby(['Store', 'Product'])
   .....:     .pipe(lambda grp: grp.Revenue.sum() / grp.Quantity.sum())
   .....:     .unstack().round(2))
   ......

Out[217]:
Product  Product_1  Product_2
Store
Store_1      6.82      7.05
Store_2      6.30      6.64
```

Piping can also be expressive when you want to deliver a grouped object to some arbitrary function, for example:

```
In [218]: def mean(groupby):
   .....:     return groupby.mean()
   ......

In [219]: df.groupby(['Store', 'Product']).pipe(mean)
Out[219]:
   Revenue  Quantity
Store    Product
Store_1 Product_1  34.622727  5.075758
          Product_2  35.482815  5.029630
Store_2 Product_1  32.972837  5.237589
          Product_2  34.684360  5.224000
```

where `mean` takes a `GroupBy` object and finds the mean of the `Revenue` and `Quantity` columns respectively for each `Store`-`Product` combination. The `mean` function can be any function that takes in a `GroupBy` object; the `.pipe` will pass the `GroupBy` object as a parameter into the function you specify.

3.13.10 Examples

Regrouping by factor

Regroup columns of a DataFrame according to their sum, and sum the aggregated ones.

```
In [220]: df = pd.DataFrame({'a': [1, 0, 0], 'b': [0, 1, 0],
.....:                 'c': [1, 0, 0], 'd': [2, 3, 4]})

In [221]: df
Out[221]:
   a  b  c  d
0  1  0  1  2
1  0  1  0  3
2  0  0  0  4

In [222]: df.groupby(df.sum(), axis=1).sum()
Out[222]:
   1  9
0  2  2
1  1  3
2  0  4
```

Multi-column factorization

By using `ngroup()`, we can extract information about the groups in a way similar to `factorize()` (as described further in the [reshaping API](#)) but which applies naturally to multiple columns of mixed type and different sources. This can be useful as an intermediate categorical-like step in processing, when the relationships between the group rows are more important than their content, or as input to an algorithm which only accepts the integer encoding. (For more information about support in pandas for full categorical data, see the [Categorical introduction](#) and the [API documentation](#).)

```
In [223]: dfg = pd.DataFrame({'A': [1, 1, 2, 3, 2], "B": list("aaaba")})

In [224]: dfg
Out[224]:
   A  B
0  1  a
1  1  a
2  2  a
3  3  b
4  2  a

In [225]: dfg.groupby(["A", "B"]).ngroup()
Out[225]:
0    0
1    0
2    1
3    2
4    1
dtype: int64

In [226]: dfg.groupby(["A", [0, 0, 0, 1, 1]]).ngroup()
Out[226]:
```

(continues on next page)

(continued from previous page)

```
0    0  
1    0  
2    1  
3    3  
4    2  
dtype: int64
```

Groupby by indexer to ‘resample’ data

Resampling produces new hypothetical samples (resamples) from already existing observed data or from a model that generates data. These new samples are similar to the pre-existing samples.

In order to resample to work on indices that are non-datetime-like, the following procedure can be utilized.

In the following examples, `df.index // 5` returns a binary array which is used to determine what gets selected for the groupby operation.

Note: The below example shows how we can downsample by consolidation of samples into fewer samples. Here by using `df.index // 5`, we are aggregating the samples in bins. By applying `std()` function, we aggregate the information contained in many samples into a small subset of values which is their standard deviation thereby reducing the number of samples.

```
In [227]: df = pd.DataFrame(np.random.randn(10, 2))  
  
In [228]: df  
Out[228]:  
          0         1  
0 -0.793893  0.321153  
1  0.342250  1.618906  
2 -0.975807  1.918201  
3 -0.810847 -1.405919  
4 -1.977759  0.461659  
5  0.730057 -1.316938  
6 -0.751328  0.528290  
7 -0.257759 -1.081009  
8  0.505895 -1.701948  
9 -1.006349  0.020208  
  
In [229]: df.index // 5  
Out[229]: Int64Index([0, 0, 0, 0, 0, 1, 1, 1, 1, 1], dtype='int64')  
  
In [230]: df.groupby(df.index // 5).std()  
Out[230]:  
          0         1  
0  0.823647  1.312912  
1  0.760109  0.942941
```

Returning a Series to propagate names

Group DataFrame columns, compute a set of metrics and return a named Series. The Series name is used as the name for the column index. This is especially useful in conjunction with reshaping operations such as stacking in which the column index name will be used as the name of the inserted column:

```
In [231]: df = pd.DataFrame({'a': [0, 0, 0, 0, 1, 1, 1, 1, 2, 2, 2, 2],  
.....: 'b': [0, 0, 1, 1, 0, 0, 1, 1, 0, 0, 1, 1],  
.....: 'c': [1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0],  
.....: 'd': [0, 0, 0, 1, 0, 0, 0, 1, 0, 0, 0, 1]})  
.....:  
  
In [232]: def compute_metrics(x):  
.....:     result = {'b_sum': x['b'].sum(), 'c_mean': x['c'].mean()}  
.....:     return pd.Series(result, name='metrics')  
.....:  
  
In [233]: result = df.groupby('a').apply(compute_metrics)  
  
In [234]: result  
Out[234]:  
metrics    b_sum    c_mean  
a  
0           2.0      0.5  
1           2.0      0.5  
2           2.0      0.5  
  
In [235]: result.stack()  
Out[235]:  
a    metrics  
0   b_sum      2.0  
    c_mean      0.5  
1   b_sum      2.0  
    c_mean      0.5  
2   b_sum      2.0  
    c_mean      0.5  
dtype: float64
```

{{ header }}

3.14 Time series / date functionality

pandas contains extensive capabilities and features for working with time series data for all domains. Using the NumPy `datetime64` and `timedelta64` dtypes, pandas has consolidated a large number of features from other Python libraries like `scikits.timeseries` as well as created a tremendous amount of new functionality for manipulating time series data.

For example, pandas supports:

Parsing time series information from various sources and formats

```
In [1]: import datetime  
  
In [2]: dti = pd.to_datetime(['1/1/2018', np.datetime64('2018-01-01'),  
....:                         datetime.datetime(2018, 1, 1)])  
....:
```

(continues on next page)

(continued from previous page)

```
In [3]: dti
Out[3]: DatetimeIndex(['2018-01-01', '2018-01-01', '2018-01-01'], dtype='datetime64[ns]', freq=None)
```

Generate sequences of fixed-frequency dates and time spans

```
In [4]: dti = pd.date_range('2018-01-01', periods=3, freq='H')
In [5]: dti
Out[5]:
DatetimeIndex(['2018-01-01 00:00:00', '2018-01-01 01:00:00',
               '2018-01-01 02:00:00'],
              dtype='datetime64[ns]', freq='H')
```

Manipulating and converting date times with timezone information

```
In [6]: dti = dti.tz_localize('UTC')
In [7]: dti
Out[7]:
DatetimeIndex(['2018-01-01 00:00:00+00:00', '2018-01-01 01:00:00+00:00',
               '2018-01-01 02:00:00+00:00'],
              dtype='datetime64[ns, UTC]', freq='H')

In [8]: dti.tz_convert('US/Pacific')
Out[8]:
DatetimeIndex(['2017-12-31 16:00:00-08:00', '2017-12-31 17:00:00-08:00',
               '2017-12-31 18:00:00-08:00'],
              dtype='datetime64[ns, US/Pacific]', freq='H')
```

Resampling or converting a time series to a particular frequency

```
In [9]: idx = pd.date_range('2018-01-01', periods=5, freq='H')
In [10]: ts = pd.Series(range(len(idx)), index=idx)
In [11]: ts
Out[11]:
2018-01-01 00:00:00    0
2018-01-01 01:00:00    1
2018-01-01 02:00:00    2
2018-01-01 03:00:00    3
2018-01-01 04:00:00    4
Freq: H, dtype: int64

In [12]: ts.resample('2H').mean()
Out[12]:
2018-01-01 00:00:00    0.5
2018-01-01 02:00:00    2.5
2018-01-01 04:00:00    4.0
Freq: 2H, dtype: float64
```

Performing date and time arithmetic with absolute or relative time increments

```
In [13]: friday = pd.Timestamp('2018-01-05')
```

(continues on next page)

(continued from previous page)

```
In [14]: friday.day_name()
Out[14]: 'Friday'

# Add 1 day
In [15]: saturday = friday + pd.Timedelta('1 day')

In [16]: saturday.day_name()
Out[16]: 'Saturday'

# Add 1 business day (Friday --> Monday)
In [17]: monday = friday + pd.offsets.BDay()

In [18]: monday.day_name()
Out[18]: 'Monday'
```

pandas provides a relatively compact and self-contained set of tools for performing the above tasks and more.

3.14.1 Overview

pandas captures 4 general time related concepts:

1. Date times: A specific date and time with timezone support. Similar to `datetime.datetime` from the standard library.
2. Time deltas: An absolute time duration. Similar to `datetime.timedelta` from the standard library.
3. Time spans: A span of time defined by a point in time and its associated frequency.
4. Date offsets: A relative time duration that respects calendar arithmetic. Similar to `dateutil.relativedelta.relativedelta` from the `dateutil` package.

Concept	Scalar Class	Array Class	pandas Data Type	Primary Creation Method
Date times	Timestamp	DatetimeIndex	<code>datetime64[ns]</code> <code>datetime64[ns, tz]</code>	<code>to_datetime</code> or <code>date_range</code>
Time deltas	Timedelta	TimedeltaIndex	<code>timedelta64[ns]</code>	<code>to_timedelta</code> or <code>timedelta_range</code>
Time spans	Period	PeriodIndex	<code>period[freq]</code>	<code>Period</code> or <code>period_range</code>
Date offsets	DateOffset	None	None	<code>DateOffset</code>

For time series data, it's conventional to represent the time component in the index of a Series or DataFrame so manipulations can be performed with respect to the time element.

```
In [19]: pd.Series(range(3), index=pd.date_range('2000', freq='D', periods=3))
Out[19]:
2000-01-01    0
2000-01-02    1
2000-01-03    2
Freq: D, dtype: int64
```

However, Series and DataFrame can directly also support the time component as data itself.

```
In [20]: pd.Series(pd.date_range('2000', freq='D', periods=3))
Out[20]:
0    2000-01-01
1    2000-01-02
2    2000-01-03
dtype: datetime64[ns]
```

Series and DataFrame have extended data type support and functionality for datetime, timedelta and Period data when passed into those constructors. DateOffset data however will be stored as object data.

```
In [21]: pd.Series(pd.period_range('1/1/2011', freq='M', periods=3))
Out[21]:
0    2011-01
1    2011-02
2    2011-03
dtype: period[M]

In [22]: pd.Series([pd.DateOffset(1), pd.DateOffset(2)])
Out[22]:
0      <DateOffset>
1    <2 * DateOffsets>
dtype: object

In [23]: pd.Series(pd.date_range('1/1/2011', freq='M', periods=3))
Out[23]:
0    2011-01-31
1    2011-02-28
2    2011-03-31
dtype: datetime64[ns]
```

Lastly, pandas represents null date times, time deltas, and time spans as NaT which is useful for representing missing or null date like values and behaves similar as np.nan does for float data.

```
In [24]: pd.Timestamp(pd.NaT)
Out[24]: NaT

In [25]: pd.Timedelta(pd.NaT)
Out[25]: NaT

In [26]: pd.Period(pd.NaT)
Out[26]: NaT

# Equality acts as np.nan would
In [27]: pd.NaT == pd.NaT
Out[27]: False
```

3.14.2 Timestamps vs. Time Spans

Timestamped data is the most basic type of time series data that associates values with points in time. For pandas objects it means using the points in time.

```
In [28]: pd.Timestamp(datetime.datetime(2012, 5, 1))
Out[28]: Timestamp('2012-05-01 00:00:00')

In [29]: pd.Timestamp('2012-05-01')
Out[29]: Timestamp('2012-05-01 00:00:00')

In [30]: pd.Timestamp(2012, 5, 1)
Out[30]: Timestamp('2012-05-01 00:00:00')
```

However, in many cases it is more natural to associate things like change variables with a time span instead. The span represented by `Period` can be specified explicitly, or inferred from datetime string format.

For example:

```
In [31]: pd.Period('2011-01')
Out[31]: Period('2011-01', 'M')

In [32]: pd.Period('2012-05', freq='D')
Out[32]: Period('2012-05-01', 'D')
```

`Timestamp` and `Period` can serve as an index. Lists of `Timestamp` and `Period` are automatically coerced to `DatetimeIndex` and `PeriodIndex` respectively.

```
In [33]: dates = [pd.Timestamp('2012-05-01'),
....:             pd.Timestamp('2012-05-02'),
....:             pd.Timestamp('2012-05-03')]
....:

In [34]: ts = pd.Series(np.random.randn(3), dates)

In [35]: type(ts.index)
Out[35]: pandas.core.indexes.datetimes.DatetimeIndex

In [36]: ts.index
Out[36]: DatetimeIndex(['2012-05-01', '2012-05-02', '2012-05-03'], dtype=
↪'datetime64[ns]', freq=None)

In [37]: ts
Out[37]:
2012-05-01    1.212707
2012-05-02   -2.219105
2012-05-03    0.930394
dtype: float64

In [38]: periods = [pd.Period('2012-01'), pd.Period('2012-02'), pd.Period('2012-03')]

In [39]: ts = pd.Series(np.random.randn(3), periods)

In [40]: type(ts.index)
Out[40]: pandas.core.indexes.period.PeriodIndex

In [41]: ts.index
Out[41]: PeriodIndex(['2012-01', '2012-02', '2012-03'], dtype='period[M]', freq='M')
```

(continues on next page)

(continued from previous page)

```
In [42]: ts
Out[42]:
2012-01    0.703754
2012-02    0.580511
2012-03   -0.135776
Freq: M, dtype: float64
```

pandas allows you to capture both representations and convert between them. Under the hood, pandas represents timestamps using instances of `Timestamp` and sequences of timestamps using instances of `DatetimeIndex`. For regular time spans, pandas uses `Period` objects for scalar values and `PeriodIndex` for sequences of spans. Better support for irregular intervals with arbitrary start and end points are forth-coming in future releases.

3.14.3 Converting to timestamps

To convert a `Series` or list-like object of date-like objects e.g. strings, epochs, or a mixture, you can use the `to_datetime` function. When passed a `Series`, this returns a `Series` (with the same index), while a list-like is converted to a `DatetimeIndex`:

```
In [43]: pd.to_datetime(pd.Series(['Jul 31, 2009', '2010-01-10', None]))
Out[43]:
0    2009-07-31
1    2010-01-10
2          NaT
dtype: datetime64[ns]

In [44]: pd.to_datetime(['2005/11/23', '2010.12.31'])
Out[44]: DatetimeIndex(['2005-11-23', '2010-12-31'], dtype='datetime64[ns]', freq=None)
```

If you use dates which start with the day first (i.e. European style), you can pass the `dayfirst` flag:

```
In [45]: pd.to_datetime(['04-01-2012 10:00'], dayfirst=True)
Out[45]: DatetimeIndex(['2012-01-04 10:00:00'], dtype='datetime64[ns]', freq=None)

In [46]: pd.to_datetime(['14-01-2012', '01-14-2012'], dayfirst=True)
Out[46]: DatetimeIndex(['2012-01-14', '2012-01-14'], dtype='datetime64[ns]', freq=None)
```

Warning: You see in the above example that `dayfirst` isn't strict, so if a date can't be parsed with the day being first it will be parsed as if `dayfirst` were False.

If you pass a single string to `to_datetime`, it returns a single `Timestamp`. `Timestamp` can also accept string input, but it doesn't accept string parsing options like `dayfirst` or `format`, so use `to_datetime` if these are required.

```
In [47]: pd.to_datetime('2010/11/12')
Out[47]: Timestamp('2010-11-12 00:00:00')

In [48]: pd.Timestamp('2010/11/12')
Out[48]: Timestamp('2010-11-12 00:00:00')
```

You can also use the `DatetimeIndex` constructor directly:

```
In [49]: pd.DatetimeIndex(['2018-01-01', '2018-01-03', '2018-01-05'])
Out[49]: DatetimeIndex(['2018-01-01', '2018-01-03', '2018-01-05'], dtype='datetime64[ns]', freq=None)
```

The string ‘infer’ can be passed in order to set the frequency of the index as the inferred frequency upon creation:

```
In [50]: pd.DatetimeIndex(['2018-01-01', '2018-01-03', '2018-01-05'], freq='infer')
Out[50]: DatetimeIndex(['2018-01-01', '2018-01-03', '2018-01-05'], dtype='datetime64[ns]', freq='2D')
```

Providing a format argument

In addition to the required datetime string, a `format` argument can be passed to ensure specific parsing. This could also potentially speed up the conversion considerably.

```
In [51]: pd.to_datetime('2010/11/12', format='%Y/%m/%d')
Out[51]: Timestamp('2010-11-12 00:00:00')

In [52]: pd.to_datetime('12-11-2010 00:00', format='%d-%m-%Y %H:%M')
Out[52]: Timestamp('2010-11-12 00:00:00')
```

For more information on the choices available when specifying the `format` option, see the Python `datetime` documentation.

Assembling datetime from multiple DataFrame columns

You can also pass a DataFrame of integer or string columns to assemble into a Series of Timestamps.

```
In [53]: df = pd.DataFrame({'year': [2015, 2016],
....:                   'month': [2, 3],
....:                   'day': [4, 5],
....:                   'hour': [2, 3]})

In [54]: pd.to_datetime(df)
Out[54]:
0    2015-02-04 02:00:00
1    2016-03-05 03:00:00
dtype: datetime64[ns]
```

You can pass only the columns that you need to assemble.

```
In [55]: pd.to_datetime(df[['year', 'month', 'day']])
Out[55]:
0    2015-02-04
1    2016-03-05
dtype: datetime64[ns]
```

`pd.to_datetime` looks for standard designations of the datetime component in the column names, including:

- required: `year`, `month`, `day`
- optional: `hour`, `minute`, `second`, `millisecond`, `microsecond`, `nanosecond`

Invalid data

The default behavior, `errors='raise'`, is to raise when unparseable:

```
In [2]: pd.to_datetime(['2009/07/31', 'asd'], errors='raise')
ValueError: Unknown string format
```

Pass `errors='ignore'` to return the original input when unparseable:

```
In [56]: pd.to_datetime(['2009/07/31', 'asd'], errors='ignore')
Out[56]: Index(['2009/07/31', 'asd'], dtype='object')
```

Pass `errors='coerce'` to convert unparseable data to NaT (not a time):

```
In [57]: pd.to_datetime(['2009/07/31', 'asd'], errors='coerce')
Out[57]: DatetimeIndex(['2009-07-31', 'NaT'], dtype='datetime64[ns]', freq=None)
```

Epoch timestamps

pandas supports converting integer or float epoch times to `Timestamp` and `DatetimeIndex`. The default unit is nanoseconds, since that is how `Timestamp` objects are stored internally. However, epochs are often stored in another unit which can be specified. These are computed from the starting point specified by the `origin` parameter.

```
In [58]: pd.to_datetime([1349720105, 1349806505, 1349892905,
....:                  1349979305, 1350065705], unit='s')
....:
Out[58]:
DatetimeIndex(['2012-10-08 18:15:05', '2012-10-09 18:15:05',
               '2012-10-10 18:15:05', '2012-10-11 18:15:05',
               '2012-10-12 18:15:05'],
              dtype='datetime64[ns]', freq=None)

In [59]: pd.to_datetime([1349720105100, 1349720105200, 1349720105300,
....:                  1349720105400, 1349720105500], unit='ms')
....:
Out[59]:
DatetimeIndex(['2012-10-08 18:15:05.100000', '2012-10-08 18:15:05.200000',
               '2012-10-08 18:15:05.300000', '2012-10-08 18:15:05.400000',
               '2012-10-08 18:15:05.500000'],
              dtype='datetime64[ns]', freq=None)
```

Constructing a `Timestamp` or `DatetimeIndex` with an epoch timestamp with the `tz` argument specified will currently localize the epoch timestamps to UTC first then convert the result to the specified time zone. However, this behavior is [deprecated](#), and if you have epochs in wall time in another timezone, it is recommended to read the epochs as timezone-naive timestamps and then localize to the appropriate timezone:

```
In [60]: pd.Timestamp(1262347200000000000).tz_localize('US/Pacific')
Out[60]: Timestamp('2010-01-01 12:00:00-0800', tz='US/Pacific')

In [61]: pd.DatetimeIndex([1262347200000000000]).tz_localize('US/Pacific')
Out[61]: DatetimeIndex(['2010-01-01 12:00:00-08:00'], dtype='datetime64[ns, US/
->Pacific]', freq=None)
```

Note: Epoch times will be rounded to the nearest nanosecond.

Warning: Conversion of float epoch times can lead to inaccurate and unexpected results. Python floats have about 15 digits precision in decimal. Rounding during conversion from float to high precision Timestamp is unavoidable. The only way to achieve exact precision is to use a fixed-width types (e.g. an int64).

```
In [62]: pd.to_datetime([1490195805.433, 1490195805.433502912], unit='s')
Out[62]: DatetimeIndex(['2017-03-22 15:16:45.433000088', '2017-03-22 15:16:45.
↪433502913'], dtype='datetime64[ns]', freq=None)

In [63]: pd.to_datetime(1490195805433502912, unit='ns')
Out[63]: Timestamp('2017-03-22 15:16:45.433502912')
```

See also:

Using the origin Parameter

From timestamps to epoch

To invert the operation from above, namely, to convert from a Timestamp to a ‘unix’ epoch:

```
In [64]: stamps = pd.date_range('2012-10-08 18:15:05', periods=4, freq='D')

In [65]: stamps
Out[65]:
DatetimeIndex(['2012-10-08 18:15:05', '2012-10-09 18:15:05',
               '2012-10-10 18:15:05', '2012-10-11 18:15:05'],
              dtype='datetime64[ns]', freq='D')
```

We subtract the epoch (midnight at January 1, 1970 UTC) and then floor divide by the “unit” (1 second).

```
In [66]: (stamps - pd.Timestamp("1970-01-01")) // pd.Timedelta('1s')
Out[66]: Int64Index([1349720105, 1349806505, 1349892905, 1349979305], dtype='int64')
```

Using the origin Parameter

Using the `origin` parameter, one can specify an alternative starting point for creation of a `DatetimeIndex`. For example, to use 1960-01-01 as the starting date:

```
In [67]: pd.to_datetime([1, 2, 3], unit='D', origin=pd.Timestamp('1960-01-01'))
Out[67]: DatetimeIndex(['1960-01-02', '1960-01-03', '1960-01-04'], dtype=
↪'datetime64[ns]', freq=None)
```

The default is set at `origin='unix'`, which defaults to 1970-01-01 00:00:00. Commonly called ‘unix epoch’ or POSIX time.

```
In [68]: pd.to_datetime([1, 2, 3], unit='D')
Out[68]: DatetimeIndex(['1970-01-02', '1970-01-03', '1970-01-04'], dtype=
↪'datetime64[ns]', freq=None)
```

3.14.4 Generating ranges of timestamps

To generate an index with timestamps, you can use either the `DatetimeIndex` or `Index` constructor and pass in a list of datetime objects:

```
In [69]: dates = [datetime.datetime(2012, 5, 1),
....:                 datetime.datetime(2012, 5, 2),
....:                 datetime.datetime(2012, 5, 3)]
....:

# Note the frequency information
In [70]: index = pd.DatetimeIndex(dates)

In [71]: index
Out[71]: DatetimeIndex(['2012-05-01', '2012-05-02', '2012-05-03'], dtype=
↪'datetime64[ns]', freq=None)

# Automatically converted to DatetimeIndex
In [72]: index = pd.Index(dates)

In [73]: index
Out[73]: DatetimeIndex(['2012-05-01', '2012-05-02', '2012-05-03'], dtype=
↪'datetime64[ns]', freq=None)
```

In practice this becomes very cumbersome because we often need a very long index with a large number of timestamps. If we need timestamps on a regular frequency, we can use the `date_range()` and `bdate_range()` functions to create a `DatetimeIndex`. The default frequency for `date_range` is a **calendar day** while the default for `bdate_range` is a **business day**:

```
In [74]: start = datetime.datetime(2011, 1, 1)

In [75]: end = datetime.datetime(2012, 1, 1)

In [76]: index = pd.date_range(start, end)

In [77]: index
Out[77]:
DatetimeIndex(['2011-01-01', '2011-01-02', '2011-01-03', '2011-01-04',
               '2011-01-05', '2011-01-06', '2011-01-07', '2011-01-08',
               '2011-01-09', '2011-01-10',
               ...,
               '2011-12-23', '2011-12-24', '2011-12-25', '2011-12-26',
               '2011-12-27', '2011-12-28', '2011-12-29', '2011-12-30',
               '2011-12-31', '2012-01-01'],
              dtype='datetime64[ns]', length=366, freq='D')

In [78]: index = pd.bdate_range(start, end)

In [79]: index
Out[79]:
DatetimeIndex(['2011-01-03', '2011-01-04', '2011-01-05', '2011-01-06',
               '2011-01-07', '2011-01-10', '2011-01-11', '2011-01-12',
               '2011-01-13', '2011-01-14',
               ...,
               '2011-12-19', '2011-12-20', '2011-12-21', '2011-12-22',
               '2011-12-23', '2011-12-26', '2011-12-27', '2011-12-28',
               '2011-12-29', '2011-12-30'],
              dtype='datetime64[ns]', length=260, freq='B')
```

Convenience functions like `date_range` and `bdate_range` can utilize a variety of *frequency aliases*:

```
In [80]: pd.date_range(start, periods=1000, freq='M')
Out[80]:
DatetimeIndex(['2011-01-31', '2011-02-28', '2011-03-31', '2011-04-30',
               '2011-05-31', '2011-06-30', '2011-07-31', '2011-08-31',
               '2011-09-30', '2011-10-31',
               ...
               '2093-07-31', '2093-08-31', '2093-09-30', '2093-10-31',
               '2093-11-30', '2093-12-31', '2094-01-31', '2094-02-28',
               '2094-03-31', '2094-04-30'],
              dtype='datetime64[ns]', length=1000, freq='M')
```

```
In [81]: pd.bdate_range(start, periods=250, freq='BQS')
Out[81]:
DatetimeIndex(['2011-01-03', '2011-04-01', '2011-07-01', '2011-10-03',
               '2012-01-02', '2012-04-02', '2012-07-02', '2012-10-01',
               '2013-01-01', '2013-04-01',
               ...
               '2071-01-01', '2071-04-01', '2071-07-01', '2071-10-01',
               '2072-01-01', '2072-04-01', '2072-07-01', '2072-10-03',
               '2073-01-02', '2073-04-03'],
              dtype='datetime64[ns]', length=250, freq='BQS-JAN')
```

`date_range` and `bdate_range` make it easy to generate a range of dates using various combinations of parameters like `start`, `end`, `periods`, and `freq`. The start and end dates are strictly inclusive, so dates outside of those specified will not be generated:

```
In [82]: pd.date_range(start, end, freq='BM')
Out[82]:
DatetimeIndex(['2011-01-31', '2011-02-28', '2011-03-31', '2011-04-29',
               '2011-05-31', '2011-06-30', '2011-07-29', '2011-08-31',
               '2011-09-30', '2011-10-31', '2011-11-30', '2011-12-30'],
              dtype='datetime64[ns]', freq='BM')
```

```
In [83]: pd.date_range(start, end, freq='W')
Out[83]:
DatetimeIndex(['2011-01-02', '2011-01-09', '2011-01-16', '2011-01-23',
               '2011-01-30', '2011-02-06', '2011-02-13', '2011-02-20',
               '2011-02-27', '2011-03-06', '2011-03-13', '2011-03-20',
               '2011-03-27', '2011-04-03', '2011-04-10', '2011-04-17',
               '2011-04-24', '2011-05-01', '2011-05-08', '2011-05-15',
               '2011-05-22', '2011-05-29', '2011-06-05', '2011-06-12',
               '2011-06-19', '2011-06-26', '2011-07-03', '2011-07-10',
               '2011-07-17', '2011-07-24', '2011-07-31', '2011-08-07',
               '2011-08-14', '2011-08-21', '2011-08-28', '2011-09-04',
               '2011-09-11', '2011-09-18', '2011-09-25', '2011-10-02',
               '2011-10-09', '2011-10-16', '2011-10-23', '2011-10-30',
               '2011-11-06', '2011-11-13', '2011-11-20', '2011-11-27',
               '2011-12-04', '2011-12-11', '2011-12-18', '2011-12-25',
               '2012-01-01'],
              dtype='datetime64[ns]', freq='W-SUN')
```

```
In [84]: pd.bdate_range(end=end, periods=20)
Out[84]:
DatetimeIndex(['2011-12-05', '2011-12-06', '2011-12-07', '2011-12-08',
               '2011-12-09', '2011-12-12', '2011-12-13', '2011-12-14',
               '2011-12-15', '2011-12-16', '2011-12-19', '2011-12-20',
```

(continues on next page)

(continued from previous page)

```
'2011-12-21', '2011-12-22', '2011-12-23', '2011-12-26',
'2011-12-27', '2011-12-28', '2011-12-29', '2011-12-30'],
dtype='datetime64[ns]', freq='B')
```

In [85]: pd.bdate_range(start=start, periods=20)

Out [85]:

```
DatetimeIndex(['2011-01-03', '2011-01-04', '2011-01-05', '2011-01-06',
                '2011-01-07', '2011-01-10', '2011-01-11', '2011-01-12',
                '2011-01-13', '2011-01-14', '2011-01-17', '2011-01-18',
                '2011-01-19', '2011-01-20', '2011-01-21', '2011-01-24',
                '2011-01-25', '2011-01-26', '2011-01-27', '2011-01-28'],
                dtype='datetime64[ns]', freq='B')
```

New in version 0.23.0.

Specifying start, end, and periods will generate a range of evenly spaced dates from start to end inclusively, with periods number of elements in the resulting DatetimeIndex:

In [86]: pd.date_range('2018-01-01', '2018-01-05', periods=5)

Out [86]:

```
DatetimeIndex(['2018-01-01', '2018-01-02', '2018-01-03', '2018-01-04',
                '2018-01-05'],
                dtype='datetime64[ns]', freq=None)
```

In [87]: pd.date_range('2018-01-01', '2018-01-05', periods=10)

Out [87]:

```
DatetimeIndex(['2018-01-01 00:00:00', '2018-01-01 10:40:00',
                '2018-01-01 21:20:00', '2018-01-02 08:00:00',
                '2018-01-02 18:40:00', '2018-01-03 05:20:00',
                '2018-01-03 16:00:00', '2018-01-04 02:40:00',
                '2018-01-04 13:20:00', '2018-01-05 00:00:00'],
                dtype='datetime64[ns]', freq=None)
```

Custom frequency ranges

bdate_range can also generate a range of custom frequency dates by using the weekmask and holidays parameters. These parameters will only be used if a custom frequency string is passed.

In [88]: weekmask = 'Mon Wed Fri'

In [89]: holidays = [datetime.datetime(2011, 1, 5), datetime.datetime(2011, 3, 14)]

In [90]: pd.bdate_range(start, end, freq='C', weekmask=weekmask, holidays=holidays)

Out [90]:

```
DatetimeIndex(['2011-01-03', '2011-01-07', '2011-01-10', '2011-01-12',
                '2011-01-14', '2011-01-17', '2011-01-19', '2011-01-21',
                '2011-01-24', '2011-01-26',
                ...
                '2011-12-09', '2011-12-12', '2011-12-14', '2011-12-16',
                '2011-12-19', '2011-12-21', '2011-12-23', '2011-12-26',
                '2011-12-28', '2011-12-30'],
                dtype='datetime64[ns]', length=154, freq='C')
```

In [91]: pd.bdate_range(start, end, freq='CBMS', weekmask=weekmask)

Out [91]:

(continues on next page)

(continued from previous page)

```
DatetimeIndex(['2011-01-03', '2011-02-02', '2011-03-02', '2011-04-01',
               '2011-05-02', '2011-06-01', '2011-07-01', '2011-08-01',
               '2011-09-02', '2011-10-03', '2011-11-02', '2011-12-02'],
              dtype='datetime64[ns]', freq='CBMS')
```

See also:*Custom business days*

3.14.5 Timestamp limitations

Since pandas represents timestamps in nanosecond resolution, the time span that can be represented using a 64-bit integer is limited to approximately 584 years:

```
In [92]: pd.Timestamp.min
Out[92]: Timestamp('1677-09-21 00:12:43.145225')

In [93]: pd.Timestamp.max
Out[93]: Timestamp('2262-04-11 23:47:16.854775807')
```

See also:*Representing out-of-bounds spans*

3.14.6 Indexing

One of the main uses for `DatetimeIndex` is as an index for pandas objects. The `DatetimeIndex` class contains many time series related optimizations:

- A large range of dates for various offsets are pre-computed and cached under the hood in order to make generating subsequent date ranges very fast (just have to grab a slice).
- Fast shifting using the `shift` and `tshift` method on pandas objects.
- Unioning of overlapping `DatetimeIndex` objects with the same frequency is very fast (important for fast data alignment).
- Quick access to date fields via properties such as `year`, `month`, etc.
- Regularization functions like `snap` and very fast `asof` logic.

`DatetimeIndex` objects have all the basic functionality of regular `Index` objects, and a smorgasbord of advanced time series specific methods for easy frequency processing.

See also:*Reindexing methods*

Note: While pandas does not force you to have a sorted date index, some of these methods may have unexpected or incorrect behavior if the dates are unsorted.

`DatetimeIndex` can be used like a regular index and offers all of its intelligent functionality like selection, slicing, etc.

```
In [94]: rng = pd.date_range(start, end, freq='BM')

In [95]: ts = pd.Series(np.random.randn(len(rng)), index=rng)

In [96]: ts.index
Out[96]:
DatetimeIndex(['2011-01-31', '2011-02-28', '2011-03-31', '2011-04-29',
               '2011-05-31', '2011-06-30', '2011-07-29', '2011-08-31',
               '2011-09-30', '2011-10-31', '2011-11-30', '2011-12-30'],
              dtype='datetime64[ns]', freq='BM')

In [97]: ts[:5].index
Out[97]:
DatetimeIndex(['2011-01-31', '2011-02-28', '2011-03-31', '2011-04-29',
               '2011-05-31'],
              dtype='datetime64[ns]', freq='BM')

In [98]: ts[::2].index
Out[98]:
DatetimeIndex(['2011-01-31', '2011-03-31', '2011-05-31', '2011-07-29',
               '2011-09-30', '2011-11-30'],
              dtype='datetime64[ns]', freq='2BM')
```

Partial string indexing

Dates and strings that parse to timestamps can be passed as indexing parameters:

```
In [99]: ts['1/31/2011']
Out[99]: 0.3135034497740378

In [100]: ts[datetime.datetime(2011, 12, 25):]
Out[100]:
2011-12-30    -0.62564
Freq: BM, dtype: float64

In [101]: ts['10/31/2011':'12/31/2011']
Out[101]:
2011-10-31    -0.042894
2011-11-30     1.321441
2011-12-30    -0.625640
Freq: BM, dtype: float64
```

To provide convenience for accessing longer time series, you can also pass in the year or year and month as strings:

```
In [102]: ts['2011']
Out[102]:
2011-01-31    0.313503
2011-02-28    1.055889
2011-03-31    0.714651
2011-04-29    0.612442
2011-05-31   -0.170038
2011-06-30   -0.828809
2011-07-29    0.458806
2011-08-31    0.764740
2011-09-30    1.917429
2011-10-31   -0.042894
```

(continues on next page)

(continued from previous page)

```
2011-11-30    1.321441
2011-12-30   -0.625640
Freq: BM, dtype: float64
```

```
In [103]: ts['2011-6']
Out[103]:
2011-06-30   -0.828809
Freq: BM, dtype: float64
```

This type of slicing will work on a DataFrame with a DatetimeIndex as well. Since the partial string selection is a form of label slicing, the endpoints **will be** included. This would include matching times on an included date:

```
In [104]: dft = pd.DataFrame(np.random.randn(100000, 1), columns=['A'],
.....:                               index=pd.date_range('20130101', periods=100000, freq='T
→ '))
.....:

In [105]: dft
Out[105]:
          A
2013-01-01 00:00:00  0.480217
2013-01-01 00:01:00  0.791875
2013-01-01 00:02:00  1.414514
2013-01-01 00:03:00 -0.801147

...
2013-02-28 23:55:00 1.819527
2013-02-28 23:56:00 0.891281
2013-02-28 23:57:00 -0.516058
2013-02-28 23:58:00 -1.350302
2013-02-28 23:59:00 1.475049
```

[84960 rows x 1 columns]

This specifies a stop time **that includes all of the times on the last day**:

```
In [108]: dft['2013-1':'2013-2-28']
```

```
Out[108]:
```

```
A
2013-01-01 00:00:00 0.480217
2013-01-01 00:01:00 0.791875
2013-01-01 00:02:00 1.414514
2013-01-01 00:03:00 -0.801147
2013-01-01 00:04:00 0.462656
...
2013-02-28 23:55:00 1.819527
2013-02-28 23:56:00 0.891281
2013-02-28 23:57:00 -0.516058
2013-02-28 23:58:00 -1.350302
2013-02-28 23:59:00 1.475049
```

[84960 rows x 1 columns]

This specifies an **exact** stop time (and is not the same as the above):

```
In [109]: dft['2013-1':'2013-2-28 00:00:00']
```

```
Out[109]:
```

```
A
2013-01-01 00:00:00 0.480217
2013-01-01 00:01:00 0.791875
2013-01-01 00:02:00 1.414514
2013-01-01 00:03:00 -0.801147
2013-01-01 00:04:00 0.462656
...
2013-02-27 23:56:00 0.032319
2013-02-27 23:57:00 0.773067
2013-02-27 23:58:00 -1.433695
2013-02-27 23:59:00 -0.759026
2013-02-28 00:00:00 0.659128
```

[83521 rows x 1 columns]

We are stopping on the included end-point as it is part of the index:

```
In [110]: dft['2013-1-15':'2013-1-15 12:30:00']
```

```
Out[110]:
```

```
A
```

(continues on next page)

(continued from previous page)

```
2013-01-15 00:00:00 -2.553103
2013-01-15 00:01:00  1.310783
2013-01-15 00:02:00  0.851770
2013-01-15 00:03:00 -0.534226
2013-01-15 00:04:00 -1.030374
...
...
2013-01-15 12:26:00  1.679647
2013-01-15 12:27:00  0.049848
2013-01-15 12:28:00 -0.722124
2013-01-15 12:29:00  0.870311
2013-01-15 12:30:00  0.360159
```

```
[751 rows x 1 columns]
```

DatetimeIndex partial string indexing also works on a DataFrame with a MultiIndex:

```
In [111]: dft2 = pd.DataFrame(np.random.randn(20, 1),
.....:                               columns=['A'],
.....:                               index=pd.MultiIndex.from_product(
.....:                                 [pd.date_range('20130101', periods=10, freq='12H'),
.....:                                  ['a', 'b']]))

In [112]: dft2
Out[112]:
          A
2013-01-01 00:00:00 a  0.030508
                  b  0.201088
2013-01-01 12:00:00 a -0.822650
                  b -0.159673
2013-01-02 00:00:00 a  0.715939
                  b  0.635435
2013-01-02 12:00:00 a  0.071542
                  b  0.539646
2013-01-03 00:00:00 a -0.743837
                  b  1.319587
2013-01-03 12:00:00 a -0.501123
                  b -0.492347
2013-01-04 00:00:00 a -0.357006
                  b -0.252463
2013-01-04 12:00:00 a -1.140700
                  b -1.367172
2013-01-05 00:00:00 a  0.048871
                  b -0.400048
2013-01-05 12:00:00 a  1.325801
                  b  0.651751

In [113]: dft2.loc['2013-01-05']
Out[113]:
          A
2013-01-05 00:00:00 a  0.048871
                  b -0.400048
2013-01-05 12:00:00 a  1.325801
                  b  0.651751

In [114]: idx = pd.IndexSlice
```

(continues on next page)

(continued from previous page)

```
In [115]: dft2 = dft2.swaplevel(0, 1).sort_index()

In [116]: dft2.loc[idx[:, '2013-01-05'], :]
Out[116]:
          A
a 2013-01-05 00:00:00  0.048871
   2013-01-05 12:00:00  1.325801
b 2013-01-05 00:00:00 -0.400048
   2013-01-05 12:00:00  0.651751
```

New in version 0.25.0.

Slicing with string indexing also honors UTC offset.

```
In [117]: df = pd.DataFrame([0], index=pd.DatetimeIndex(['2019-01-01'], tz='US/Pacific
           '))
In [118]: df
Out[118]:
          0
2019-01-01 00:00:00-08:00  0

In [119]: df['2019-01-01 12:00:00+04:00':'2019-01-01 13:00:00+04:00']
Out[119]:
          0
2019-01-01 00:00:00-08:00  0
```

Slice vs. exact match

Changed in version 0.20.0.

The same string used as an indexing parameter can be treated either as a slice or as an exact match depending on the resolution of the index. If the string is less accurate than the index, it will be treated as a slice, otherwise as an exact match.

Consider a Series object with a minute resolution index:

```
In [120]: series_minute = pd.Series([1, 2, 3],
           .....:                     pd.DatetimeIndex(['2011-12-31 23:59:00',
           .....:                           '2012-01-01 00:00:00',
           .....:                           '2012-01-01 00:02:00'])))
In [121]: series_minute.index.resolution
Out[121]: 'minute'
```

A timestamp string less accurate than a minute gives a Series object.

```
In [122]: series_minute['2011-12-31 23']
Out[122]:
2011-12-31 23:59:00      1
dtype: int64
```

A timestamp string with minute resolution (or more accurate), gives a scalar instead, i.e. it is not casted to a slice.

```
In [123]: series_minute['2011-12-31 23:59']
Out[123]: 1

In [124]: series_minute['2011-12-31 23:59:00']
Out[124]: 1
```

If index resolution is second, then the minute-accurate timestamp gives a Series.

```
In [125]: series_second = pd.Series([1, 2, 3],
.....:                               pd.DatetimeIndex(['2011-12-31 23:59:59',
.....:                               '2012-01-01 00:00:00',
.....:                               '2012-01-01 00:00:01']))
.....:

In [126]: series_second.index.resolution
Out[126]: 'second'

In [127]: series_second['2011-12-31 23:59']
Out[127]:
2011-12-31 23:59:59    1
dtype: int64
```

If the timestamp string is treated as a slice, it can be used to index DataFrame with [] as well.

```
In [128]: dft_minute = pd.DataFrame({'a': [1, 2, 3], 'b': [4, 5, 6]},
.....:                               index=series_minute.index)
.....:

In [129]: dft_minute['2011-12-31 23']
Out[129]:
   a   b
2011-12-31 23:59:00  1   4
```

Warning: However, if the string is treated as an exact match, the selection in DataFrame's [] will be column-wise and not row-wise, see [Indexing Basics](#). For example `dft_minute['2011-12-31 23:59']` will raise `KeyError` as '2012-12-31 23:59' has the same resolution as the index and there is no column with such name:

To *always* have unambiguous selection, whether the row is treated as a slice or a single selection, use `.loc`.

```
In [130]: dft_minute.loc['2011-12-31 23:59']
Out[130]:
a    1
b    4
Name: 2011-12-31 23:59:00, dtype: int64
```

Note also that DatetimeIndex resolution cannot be less precise than day.

```
In [131]: series_monthly = pd.Series([1, 2, 3],
.....:                               pd.DatetimeIndex(['2011-12', '2012-01', '2012-02
.....:                               ']))
.....:

In [132]: series_monthly.index.resolution
Out[132]: 'day'
```

(continues on next page)

(continued from previous page)

```
In [133]: series_monthly['2011-12'] # returns Series
Out[133]:
2011-12-01    1
dtype: int64
```

Exact indexing

As discussed in previous section, indexing a `DatetimeIndex` with a partial string depends on the “accuracy” of the period, in other words how specific the interval is in relation to the resolution of the index. In contrast, indexing with `Timestamp` or `datetime` objects is exact, because the objects have exact meaning. These also follow the semantics of *including both endpoints*.

These `Timestamp` and `datetime` objects have exact hours, minutes, and seconds, even though they were not explicitly specified (they are 0).

```
In [134]: dft[datetime.datetime(2013, 1, 1):datetime.datetime(2013, 2, 28)]
Out[134]:
          A
2013-01-01 00:00:00  0.480217
2013-01-01 00:01:00  0.791875
2013-01-01 00:02:00  1.414514
2013-01-01 00:03:00 -0.801147
2013-01-01 00:04:00  0.462656
...
2013-02-27 23:56:00  0.032319
2013-02-27 23:57:00  0.773067
2013-02-27 23:58:00 -1.433695
2013-02-27 23:59:00 -0.759026
2013-02-28 00:00:00  0.659128

[83521 rows x 1 columns]
```

With no defaults.

```
In [135]: dft[datetime.datetime(2013, 1, 1, 10, 12, 0):
.....:     datetime.datetime(2013, 2, 28, 10, 12, 0)]
.....:
Out[135]:
          A
2013-01-01 10:12:00  0.827464
2013-01-01 10:13:00 -2.923827

```

Truncating & fancy indexing

A `truncate()` convenience function is provided that is similar to slicing. Note that `truncate` assumes a 0 value for any unspecified date component in a `DatetimeIndex` in contrast to slicing which returns any partially matching dates:

```
In [136]: rng2 = pd.date_range('2011-01-01', '2012-01-01', freq='W')
In [137]: ts2 = pd.Series(np.random.randn(len(rng2)), index=rng2)
In [138]: ts2.truncate(before='2011-11', after='2011-12')
Out[138]:
2011-11-06    0.524645
2011-11-13    0.027878
2011-11-20   -0.914186
2011-11-27    0.672453
Freq: W-SUN, dtype: float64

In [139]: ts2['2011-11':'2011-12']
Out[139]:
2011-11-06    0.524645
2011-11-13    0.027878
2011-11-20   -0.914186
2011-11-27    0.672453
2011-12-04   -0.698538
2011-12-11    1.048716
2011-12-18    0.158099
2011-12-25    1.605115
Freq: W-SUN, dtype: float64
```

Even complicated fancy indexing that breaks the `DatetimeIndex` frequency regularity will result in a `DatetimeIndex`, although frequency is lost:

```
In [140]: ts2[[0, 2, 6]].index
Out[140]: DatetimeIndex(['2011-01-02', '2011-01-16', '2011-02-13'], dtype='datetime64[ns]', freq=None)
```

3.14.7 Time/date components

There are several time/date properties that one can access from `Timestamp` or a collection of timestamps like a `DatetimeIndex`.

Property	Description
year	The year of the datetime
month	The month of the datetime
day	The days of the datetime
hour	The hour of the datetime
minute	The minutes of the datetime
second	The seconds of the datetime
microsecond	The microseconds of the datetime
nanosecond	The nanoseconds of the datetime
date	Returns datetime.date (does not contain timezone information)
time	Returns datetime.time (does not contain timezone information)
timetz	Returns datetime.time as local time with timezone information
dayofyear	The ordinal day of year
weekofyear	The week ordinal of the year
week	The week ordinal of the year
dayofweek	The number of the day of the week with Monday=0, Sunday=6
weekday	The number of the day of the week with Monday=0, Sunday=6
quarter	Quarter of the date: Jan-Mar = 1, Apr-Jun = 2, etc.
days_in_month	The number of days in the month of the datetime
is_month_start	Logical indicating if first day of month (defined by frequency)
is_month_end	Logical indicating if last day of month (defined by frequency)
is_quarter_start	Logical indicating if first day of quarter (defined by frequency)
is_quarter_end	Logical indicating if last day of quarter (defined by frequency)
is_year_start	Logical indicating if first day of year (defined by frequency)
is_year_end	Logical indicating if last day of year (defined by frequency)
is_leap_year	Logical indicating if the date belongs to a leap year

Furthermore, if you have a Series with datetimelike values, then you can access these properties via the .dt accessor, as detailed in the section on [.dt accessors](#).

3.14.8 DateOffset objects

In the preceding examples, frequency strings (e.g. 'D') were used to specify a frequency that defined:

- how the date times in DatetimeIndex were spaced when using `date_range()`
- the frequency of a Period or PeriodIndex

These frequency strings map to a DateOffset object and its subclasses. A DateOffset is similar to a Timedelta that represents a duration of time but follows specific calendar duration rules. For example, a Timedelta day will always increment datetimes by 24 hours, while a DateOffset day will increment datetimes to the same time the next day whether a day represents 23, 24 or 25 hours due to daylight savings time. However, all DateOffset subclasses that are an hour or smaller (Hour, Minute, Second, Milli, Micro, Nano) behave like Timedelta and respect absolute time.

The basic DateOffset acts similar to `dateutil.relativedelta` ([relativedelta documentation](#)) that shifts a date time by the corresponding calendar duration specified. The arithmetic operator (+) or the `apply` method can be used to perform the shift.

```
# This particular day contains a day light savings time transition
In [141]: ts = pd.Timestamp('2016-10-30 00:00:00', tz='Europe/Helsinki')

# Respects absolute time
```

(continues on next page)

(continued from previous page)

```
In [142]: ts + pd.Timedelta(days=1)
Out[142]: Timestamp('2016-10-30 23:00:00+0200', tz='Europe/Helsinki')

# Respects calendar time
In [143]: ts + pd.DateOffset(days=1)
Out[143]: Timestamp('2016-10-31 00:00:00+0200', tz='Europe/Helsinki')

In [144]: friday = pd.Timestamp('2018-01-05')

In [145]: friday.day_name()
Out[145]: 'Friday'

# Add 2 business days (Friday --> Tuesday)
In [146]: two_business_days = 2 * pd.offsets.BDay()

In [147]: two_business_days.apply(friday)
Out[147]: Timestamp('2018-01-09 00:00:00')

In [148]: friday + two_business_days
Out[148]: Timestamp('2018-01-09 00:00:00')

In [149]: (friday + two_business_days).day_name()
Out[149]: 'Tuesday'
```

Most DateOffsets have associated frequencies strings, or offset aliases, that can be passed into `freq` keyword arguments. The available date offsets and associated frequency strings can be found below:

Date Offset	Frequency String	Description
<code>DateOffset</code>	None	Generic offset class, defaults to 1 calendar day
<code>BDay</code> or <code>BusinessDay</code>	'B'	business day (weekday)
<code>CDay</code> or <code>CustomBusinessDay</code>	'C'	custom business day
<code>Week</code>	'W'	one week, optionally anchored on a day of the week
<code>WeekOfMonth</code>	'WOM'	the x-th day of the y-th week of each month
<code>LastWeekOfMonth</code>	'LWOM'	the x-th day of the last week of each month
<code>MonthEnd</code>	'M'	calendar month end
<code>MonthBegin</code>	'MS'	calendar month begin
<code>BMonthEnd</code> or <code>BusinessMonthEnd</code>	'BM'	business month end
<code>BMonthBegin</code> or <code>BusinessMonthBegin</code>	'BMS'	business month begin
<code>CBMonthEnd</code> or <code>CustomBusinessMonthEnd</code>	'CBM'	custom business month end
<code>CBMonthBegin</code> or <code>CustomBusinessMonthBegin</code>	'CBMS'	custom business month begin
<code>SemiMonthEnd</code>	'SM'	15th (or other day_of_month) and calendar month end
<code>SemiMonthBegin</code>	'SMS'	15th (or other day_of_month) and calendar month begin

Continued on next page

Table 3 – continued from previous page

Date Offset	Frequency String	Description
<i>QuarterEnd</i>	'Q'	calendar quarter end
<i>QuarterBegin</i>	'QS'	calendar quarter begin
<i>BQuarterEnd</i>	'BQ'	business quarter end
<i>BQuarterBegin</i>	'BQS'	business quarter begin
<i>FY5253Quarter</i>	'REQ'	retail (aka 52-53 week) quarter
<i>YearEnd</i>	'A'	calendar year end
<i>YearBegin</i>	'AS' or 'BYS'	calendar year begin
<i>BYearEnd</i>	'BA'	business year end
<i>BYearBegin</i>	'BAS'	business year begin
<i>FY5253</i>	'RE'	retail (aka 52-53 week) year
<i>Easter</i>	None	Easter holiday
<i>BusinessHour</i>	'BH'	business hour
<i>CustomBusinessHour</i>	'CBH'	custom business hour
<i>Day</i>	'D'	one absolute day
<i>Hour</i>	'H'	one hour
<i>Minute</i>	'T' or 'min'	one minute
<i>Second</i>	'S'	one second
<i>Milli</i>	'L' or 'ms'	one millisecond
<i>Micro</i>	'U' or 'us'	one microsecond
<i>Nano</i>	'N'	one nanosecond

DateOffsets additionally have `rollforward()` and `rollback()` methods for moving a date forward or backward respectively to a valid offset date relative to the offset. For example, business offsets will roll dates that land on the weekends (Saturday and Sunday) forward to Monday since business offsets operate on the weekdays.

```
In [150]: ts = pd.Timestamp('2018-01-06 00:00:00')

In [151]: ts.day_name()
Out[151]: 'Saturday'

# BusinessHour's valid offset dates are Monday through Friday
In [152]: offset = pd.offsets.BusinessHour(start='09:00')

# Bring the date to the closest offset date (Monday)
In [153]: offset.rollforward(ts)
Out[153]: Timestamp('2018-01-08 09:00:00')

# Date is brought to the closest offset date first and then the hour is added
In [154]: ts + offset
Out[154]: Timestamp('2018-01-08 10:00:00')
```

These operations preserve time (hour, minute, etc) information by default. To reset time to midnight, use `normalize()` before or after applying the operation (depending on whether you want the time information included in the operation).

```
In [155]: ts = pd.Timestamp('2014-01-01 09:00')

In [156]: day = pd.offsets.Day()

In [157]: day.apply(ts)
Out[157]: Timestamp('2014-01-02 09:00:00')
```

(continues on next page)

(continued from previous page)

```
In [158]: day.apply(ts).normalize()
Out[158]: Timestamp('2014-01-02 00:00:00')

In [159]: ts = pd.Timestamp('2014-01-01 22:00')

In [160]: hour = pd.offsets.Hour()

In [161]: hour.apply(ts)
Out[161]: Timestamp('2014-01-01 23:00:00')

In [162]: hour.apply(ts).normalize()
Out[162]: Timestamp('2014-01-01 00:00:00')

In [163]: hour.apply(pd.Timestamp("2014-01-01 23:30")).normalize()
Out[163]: Timestamp('2014-01-02 00:00:00')
```

Parametric offsets

Some of the offsets can be “parameterized” when created to result in different behaviors. For example, the Week offset for generating weekly data accepts a weekday parameter which results in the generated dates always lying on a particular day of the week:

```
In [164]: d = datetime.datetime(2008, 8, 18, 9, 0)

In [165]: d
Out[165]: datetime.datetime(2008, 8, 18, 9, 0)

In [166]: d + pd.offsets.Week()
Out[166]: Timestamp('2008-08-25 09:00:00')

In [167]: d + pd.offsets.Week(weekday=4)
Out[167]: Timestamp('2008-08-22 09:00:00')

In [168]: (d + pd.offsets.Week(weekday=4)).weekday()
Out[168]: 4

In [169]: d - pd.offsets.Week()
Out[169]: Timestamp('2008-08-11 09:00:00')
```

The normalize option will be effective for addition and subtraction.

```
In [170]: d + pd.offsets.Week(normalize=True)
Out[170]: Timestamp('2008-08-25 00:00:00')

In [171]: d - pd.offsets.Week(normalize=True)
Out[171]: Timestamp('2008-08-11 00:00:00')
```

Another example is parameterizing YearEnd with the specific ending month:

```
In [172]: d + pd.offsets.YearEnd()
Out[172]: Timestamp('2008-12-31 09:00:00')

In [173]: d + pd.offsets.YearEnd(month=6)
Out[173]: Timestamp('2009-06-30 09:00:00')
```

Using offsets with Series / DatetimeIndex

Offsets can be used with either a Series or DatetimeIndex to apply the offset to each element.

```
In [174]: rng = pd.date_range('2012-01-01', '2012-01-03')

In [175]: s = pd.Series(rng)

In [176]: rng
Out[176]: DatetimeIndex(['2012-01-01', '2012-01-02', '2012-01-03'], dtype='datetime64[ns]', freq='D')

In [177]: rng + pd.DateOffset(months=2)
Out[177]: DatetimeIndex(['2012-03-01', '2012-03-02', '2012-03-03'], dtype='datetime64[ns]', freq='D')

In [178]: s + pd.DateOffset(months=2)
Out[178]:
0    2012-03-01
1    2012-03-02
2    2012-03-03
dtype: datetime64[ns]

In [179]: s - pd.DateOffset(months=2)
Out[179]:
0    2011-11-01
1    2011-11-02
2    2011-11-03
dtype: datetime64[ns]
```

If the offset class maps directly to a Timedelta (Day, Hour, Minute, Second, Micro, Milli, Nano) it can be used exactly like a Timedelta - see the [Timedelta section](#) for more examples.

```
In [180]: s - pd.offsets.Day(2)
Out[180]:
0    2011-12-30
1    2011-12-31
2    2012-01-01
dtype: datetime64[ns]

In [181]: td = s - pd.Series(pd.date_range('2011-12-29', '2011-12-31'))

In [182]: td
Out[182]:
0    3 days
1    3 days
2    3 days
dtype: timedelta64[ns]

In [183]: td + pd.offsets.Minute(15)
Out[183]:
0    3 days 00:15:00
1    3 days 00:15:00
2    3 days 00:15:00
dtype: timedelta64[ns]
```

Note that some offsets (such as BQuarterEnd) do not have a vectorized implementation. They can still be used but may calculate significantly slower and will show a PerformanceWarning

```
In [184]: rng + pd.offsets.BQuarterEnd()
Out[184]: DatetimeIndex(['2012-03-30', '2012-03-30', '2012-03-30'], dtype='datetime64[ns]', freq='D')
```

Custom business days

The CDay or CustomBusinessDay class provides a parametric BusinessDay class which can be used to create customized business day calendars which account for local holidays and local weekend conventions.

As an interesting example, let's look at Egypt where a Friday-Saturday weekend is observed.

```
In [185]: weekmask_egypt = 'Sun Mon Tue Wed Thu'

# They also observe International Workers' Day so let's
# add that for a couple of years
In [186]: holidays = ['2012-05-01',
.....:             datetime.datetime(2013, 5, 1),
.....:             np.datetime64('2014-05-01')]
.....:

In [187]: bday_egypt = pd.offsets.CustomBusinessDay(holidays=holidays,
.....:                                                 weekmask=weekmask_egypt)
.....:

In [188]: dt = datetime.datetime(2013, 4, 30)

In [189]: dt + 2 * bday_egypt
Out[189]: Timestamp('2013-05-05 00:00:00')
```

Let's map to the weekday names:

```
In [190]: dts = pd.date_range(dt, periods=5, freq=bday_egypt)

In [191]: pd.Series(dts.weekday, dts).map(
.....:     pd.Series('Mon Tue Wed Thu Fri Sat Sun'.split()))
.....:

Out[191]:
2013-04-30    Tue
2013-05-02    Thu
2013-05-05    Sun
2013-05-06    Mon
2013-05-07    Tue
Freq: C, dtype: object
```

Holiday calendars can be used to provide the list of holidays. See the [holiday calendar](#) section for more information.

```
In [192]: from pandas.tseries.holiday import USFederalHolidayCalendar

In [193]: bday_us = pd.offsets.CustomBusinessDay(calendar=USFederalHolidayCalendar())

# Friday before MLK Day
In [194]: dt = datetime.datetime(2014, 1, 17)

# Tuesday after MLK Day (Monday is skipped because it's a holiday)
In [195]: dt + bday_us
Out[195]: Timestamp('2014-01-21 00:00:00')
```

Monthly offsets that respect a certain holiday calendar can be defined in the usual way.

```
In [196]: bmth_us = pd.offsets.CustomBusinessMonthBegin(  
.....:     calendar=USFederalHolidayCalendar())  
.....:  
  
# Skip new years  
In [197]: dt = datetime.datetime(2013, 12, 17)  
  
In [198]: dt + bmth_us  
Out[198]: Timestamp('2014-01-02 00:00:00')  
  
# Define date index with custom offset  
In [199]: pd.date_range(start='20100101', end='20120101', freq=bmth_us)  
Out[199]:  
DatetimeIndex(['2010-01-04', '2010-02-01', '2010-03-01', '2010-04-01',  
              '2010-05-03', '2010-06-01', '2010-07-01', '2010-08-02',  
              '2010-09-01', '2010-10-01', '2010-11-01', '2010-12-01',  
              '2011-01-03', '2011-02-01', '2011-03-01', '2011-04-01',  
              '2011-05-02', '2011-06-01', '2011-07-01', '2011-08-01',  
              '2011-09-01', '2011-10-03', '2011-11-01', '2011-12-01'],  
             dtype='datetime64[ns]', freq='CBMS')
```

Note: The frequency string ‘C’ is used to indicate that a CustomBusinessDay DateOffset is used, it is important to note that since CustomBusinessDay is a parameterised type, instances of CustomBusinessDay may differ and this is not detectable from the ‘C’ frequency string. The user therefore needs to ensure that the ‘C’ frequency string is used consistently within the user’s application.

Business hour

The BusinessHour class provides a business hour representation on BusinessDay, allowing to use specific start and end times.

By default, BusinessHour uses 9:00 - 17:00 as business hours. Adding BusinessHour will increment Timestamp by hourly frequency. If target Timestamp is out of business hours, move to the next business hour then increment it. If the result exceeds the business hours end, the remaining hours are added to the next business day.

```
In [200]: bh = pd.offsets.BusinessHour()  
  
In [201]: bh  
Out[201]: <BusinessHour: BH=09:00-17:00>  
  
# 2014-08-01 is Friday  
In [202]: pd.Timestamp('2014-08-01 10:00').weekday()  
Out[202]: 4  
  
In [203]: pd.Timestamp('2014-08-01 10:00') + bh  
Out[203]: Timestamp('2014-08-01 11:00:00')  
  
# Below example is the same as: pd.Timestamp('2014-08-01 09:00') + bh  
In [204]: pd.Timestamp('2014-08-01 08:00') + bh  
Out[204]: Timestamp('2014-08-01 10:00:00')  
  
# If the results is on the end time, move to the next business day
```

(continues on next page)

(continued from previous page)

```
In [205]: pd.Timestamp('2014-08-01 16:00') + bh
Out[205]: Timestamp('2014-08-04 09:00:00')

# Remainings are added to the next day
In [206]: pd.Timestamp('2014-08-01 16:30') + bh
Out[206]: Timestamp('2014-08-04 09:30:00')

# Adding 2 business hours
In [207]: pd.Timestamp('2014-08-01 10:00') + pd.offsets.BusinessHour(2)
Out[207]: Timestamp('2014-08-01 12:00:00')

# Subtracting 3 business hours
In [208]: pd.Timestamp('2014-08-01 10:00') + pd.offsets.BusinessHour(-3)
Out[208]: Timestamp('2014-07-31 15:00:00')
```

You can also specify start and end time by keywords. The argument must be a str with an hour:minute representation or a datetime.time instance. Specifying seconds, microseconds and nanoseconds as business hour results in ValueError.

```
In [209]: bh = pd.offsets.BusinessHour(start='11:00', end=datetime.time(20, 0))

In [210]: bh
Out[210]: <BusinessHour: BH=11:00-20:00>

In [211]: pd.Timestamp('2014-08-01 13:00') + bh
Out[211]: Timestamp('2014-08-01 14:00:00')

In [212]: pd.Timestamp('2014-08-01 09:00') + bh
Out[212]: Timestamp('2014-08-01 12:00:00')

In [213]: pd.Timestamp('2014-08-01 18:00') + bh
Out[213]: Timestamp('2014-08-01 19:00:00')
```

Passing start time later than end represents midnight business hour. In this case, business hour exceeds midnight and overlap to the next day. Valid business hours are distinguished by whether it started from valid BusinessDay.

```
In [214]: bh = pd.offsets.BusinessHour(start='17:00', end='09:00')

In [215]: bh
Out[215]: <BusinessHour: BH=17:00-09:00>

In [216]: pd.Timestamp('2014-08-01 17:00') + bh
Out[216]: Timestamp('2014-08-01 18:00:00')

In [217]: pd.Timestamp('2014-08-01 23:00') + bh
Out[217]: Timestamp('2014-08-02 00:00:00')

# Although 2014-08-02 is Saturday,
# it is valid because it starts from 08-01 (Friday).
In [218]: pd.Timestamp('2014-08-02 04:00') + bh
Out[218]: Timestamp('2014-08-02 05:00:00')

# Although 2014-08-04 is Monday,
# it is out of business hours because it starts from 08-03 (Sunday).
In [219]: pd.Timestamp('2014-08-04 04:00') + bh
Out[219]: Timestamp('2014-08-04 18:00:00')
```

Applying `BusinessHour.rollforward` and `rollback` to out of business hours results in the next business hour start or previous day's end. Different from other offsets, `BusinessHour.rollforward` may output different results from `apply` by definition.

This is because one day's business hour end is equal to next day's business hour start. For example, under the default business hours (9:00 - 17:00), there is no gap (0 minutes) between 2014-08-01 17:00 and 2014-08-04 09:00.

```
# This adjusts a Timestamp to business hour edge
In [220]: pd.offsets.BusinessHour().rollback(pd.Timestamp('2014-08-02 15:00'))
Out[220]: Timestamp('2014-08-01 17:00:00')

In [221]: pd.offsets.BusinessHour().rollforward(pd.Timestamp('2014-08-02 15:00'))
Out[221]: Timestamp('2014-08-04 09:00:00')

# It is the same as BusinessHour().apply(pd.Timestamp('2014-08-01 17:00')) .
# And it is the same as BusinessHour().apply(pd.Timestamp('2014-08-04 09:00')) 
In [222]: pd.offsets.BusinessHour().apply(pd.Timestamp('2014-08-02 15:00'))
Out[222]: Timestamp('2014-08-04 10:00:00')

# BusinessDay results (for reference)
In [223]: pd.offsets.BusinessHour().rollforward(pd.Timestamp('2014-08-02'))
Out[223]: Timestamp('2014-08-04 09:00:00')

# It is the same as BusinessDay().apply(pd.Timestamp('2014-08-01'))
# The result is the same as rollwoward because BusinessDay never overlap.
In [224]: pd.offsets.BusinessHour().apply(pd.Timestamp('2014-08-02'))
Out[224]: Timestamp('2014-08-04 10:00:00')
```

`BusinessHour` regards Saturday and Sunday as holidays. To use arbitrary holidays, you can use `CustomBusinessHour` offset, as explained in the following subsection.

Custom business hour

The `CustomBusinessHour` is a mixture of `BusinessHour` and `CustomBusinessDay` which allows you to specify arbitrary holidays. `CustomBusinessHour` works as the same as `BusinessHour` except that it skips specified custom holidays.

```
In [225]: from pandas.tseries.holiday import USFederalHolidayCalendar

In [226]: bhour_us = pd.offsets.
↪CustomBusinessHour(calendar=USFederalHolidayCalendar())

# Friday before MLK Day
In [227]: dt = datetime.datetime(2014, 1, 17, 15)

In [228]: dt + bhour_us
Out[228]: Timestamp('2014-01-17 16:00:00')

# Tuesday after MLK Day (Monday is skipped because it's a holiday)
In [229]: dt + bhour_us * 2
Out[229]: Timestamp('2014-01-21 09:00:00')
```

You can use keyword arguments supported by either `BusinessHour` and `CustomBusinessDay`.

```
In [230]: bhour_mon = pd.offsets.CustomBusinessHour(start='10:00',
.....:
                                                               weekmask='Tue Wed Thu Fri')
```

(continues on next page)

(continued from previous page)

```
....:  

# Monday is skipped because it's a holiday, business hour starts from 10:00  

In [231]: dt + bhour_mon * 2  

Out[231]: Timestamp('2014-01-21 10:00:00')
```

Offset aliases

A number of string aliases are given to useful common time series frequencies. We will refer to these aliases as *offset aliases*.

Alias	Description
B	business day frequency
C	custom business day frequency
D	calendar day frequency
W	weekly frequency
M	month end frequency
SM	semi-month end frequency (15th and end of month)
BM	business month end frequency
CBM	custom business month end frequency
MS	month start frequency
SMS	semi-month start frequency (1st and 15th)
BMS	business month start frequency
CBMS	custom business month start frequency
Q	quarter end frequency
BQ	business quarter end frequency
QS	quarter start frequency
BQS	business quarter start frequency
A, Y	year end frequency
BA, BY	business year end frequency
AS, YS	year start frequency
BAS, BYS	business year start frequency
BH	business hour frequency
H	hourly frequency
T, min	minutely frequency
S	secondly frequency
L, ms	milliseconds
U, us	microseconds
N	nanoseconds

Combining aliases

As we have seen previously, the alias and the offset instance are fungible in most functions:

```
In [232]: pd.date_range(start, periods=5, freq='B')  

Out[232]:  

DatetimeIndex(['2011-01-03', '2011-01-04', '2011-01-05', '2011-01-06',  

               '2011-01-07'],  

              dtype='datetime64[ns]', freq='B')
```

(continues on next page)

(continued from previous page)

```
In [233]: pd.date_range(start, periods=5, freq=pd.offsets.BDay())
Out[233]:
DatetimeIndex(['2011-01-03', '2011-01-04', '2011-01-05', '2011-01-06',
               '2011-01-07'],
              dtype='datetime64[ns]', freq='B')
```

You can combine together day and intraday offsets:

```
In [234]: pd.date_range(start, periods=10, freq='2h20min')
Out[234]:
DatetimeIndex(['2011-01-01 00:00:00', '2011-01-01 02:20:00',
               '2011-01-01 04:40:00', '2011-01-01 07:00:00',
               '2011-01-01 09:20:00', '2011-01-01 11:40:00',
               '2011-01-01 14:00:00', '2011-01-01 16:20:00',
               '2011-01-01 18:40:00', '2011-01-01 21:00:00'],
              dtype='datetime64[ns]', freq='140T')

In [235]: pd.date_range(start, periods=10, freq='1D10U')
Out[235]:
DatetimeIndex(['2011-01-01 00:00:00', '2011-01-02 00:00:00.000010',
               '2011-01-03 00:00:00.000020', '2011-01-04 00:00:00.000030',
               '2011-01-05 00:00:00.000040', '2011-01-06 00:00:00.000050',
               '2011-01-07 00:00:00.000060', '2011-01-08 00:00:00.000070',
               '2011-01-09 00:00:00.000080', '2011-01-10 00:00:00.000090'],
              dtype='datetime64[ns]', freq='86400000010U')
```

Anchored offsets

For some frequencies you can specify an anchoring suffix:

Alias	Description
W-SUN	weekly frequency (Sundays). Same as 'W'
W-MON	weekly frequency (Mondays)
W-TUE	weekly frequency (Tuesdays)
W-WED	weekly frequency (Wednesdays)
W-THU	weekly frequency (Thursdays)
W-FRI	weekly frequency (Fridays)
W-SAT	weekly frequency (Saturdays)
(B)Q(S)-DEC	quarterly frequency, year ends in December. Same as 'Q'
(B)Q(S)-JAN	quarterly frequency, year ends in January
(B)Q(S)-FEB	quarterly frequency, year ends in February
(B)Q(S)-MAR	quarterly frequency, year ends in March
(B)Q(S)-APR	quarterly frequency, year ends in April
(B)Q(S)-MAY	quarterly frequency, year ends in May
(B)Q(S)-JUN	quarterly frequency, year ends in June

Continued on next page

Table 4 – continued from previous page

Alias	Description
(B)Q(S)-JUL	quarterly frequency, year ends in July
(B)Q(S)-AUG	quarterly frequency, year ends in August
(B)Q(S)-SEP	quarterly frequency, year ends in September
(B)Q(S)-OCT	quarterly frequency, year ends in October
(B)Q(S)-NOV	quarterly frequency, year ends in November
(B)A(S)-DEC	annual frequency, anchored end of December. Same as 'A'
(B)A(S)-JAN	annual frequency, anchored end of January
(B)A(S)-FEB	annual frequency, anchored end of February
(B)A(S)-MAR	annual frequency, anchored end of March
(B)A(S)-APR	annual frequency, anchored end of April
(B)A(S)-MAY	annual frequency, anchored end of May
(B)A(S)-JUN	annual frequency, anchored end of June
(B)A(S)-JUL	annual frequency, anchored end of July
(B)A(S)-AUG	annual frequency, anchored end of August
(B)A(S)-SEP	annual frequency, anchored end of September
(B)A(S)-OCT	annual frequency, anchored end of October
(B)A(S)-NOV	annual frequency, anchored end of November

These can be used as arguments to `date_range`, `bdate_range`, constructors for `DatetimeIndex`, as well as various other timeseries-related functions in pandas.

Anchored offset semantics

For those offsets that are anchored to the start or end of specific frequency (`MonthEnd`, `MonthBegin`, `WeekEnd`, etc), the following rules apply to rolling forward and backwards.

When n is not 0, if the given date is not on an anchor point, it snapped to the next(previous) anchor point, and moved $|n| - 1$ additional steps forwards or backwards.

```
In [236]: pd.Timestamp('2014-01-02') + pd.offsets.MonthBegin(n=1)
Out[236]: Timestamp('2014-02-01 00:00:00')
```

```
In [237]: pd.Timestamp('2014-01-02') + pd.offsets.MonthEnd(n=1)
Out[237]: Timestamp('2014-01-31 00:00:00')
```

(continues on next page)

(continued from previous page)

```
In [238]: pd.Timestamp('2014-01-02') - pd.offsets.MonthBegin(n=1)
Out[238]: Timestamp('2014-01-01 00:00:00')
```

```
In [239]: pd.Timestamp('2014-01-02') - pd.offsets.MonthEnd(n=1)
Out[239]: Timestamp('2013-12-31 00:00:00')
```

```
In [240]: pd.Timestamp('2014-01-02') + pd.offsets.MonthBegin(n=4)
Out[240]: Timestamp('2014-05-01 00:00:00')
```

```
In [241]: pd.Timestamp('2014-01-02') - pd.offsets.MonthBegin(n=4)
Out[241]: Timestamp('2013-10-01 00:00:00')
```

If the given date *is* on an anchor point, it is moved $|n|$ points forwards or backwards.

```
In [242]: pd.Timestamp('2014-01-01') + pd.offsets.MonthBegin(n=1)
Out[242]: Timestamp('2014-02-01 00:00:00')
```

```
In [243]: pd.Timestamp('2014-01-31') + pd.offsets.MonthEnd(n=1)
Out[243]: Timestamp('2014-02-28 00:00:00')
```

```
In [244]: pd.Timestamp('2014-01-01') - pd.offsets.MonthBegin(n=1)
Out[244]: Timestamp('2013-12-01 00:00:00')
```

```
In [245]: pd.Timestamp('2014-01-31') - pd.offsets.MonthEnd(n=1)
Out[245]: Timestamp('2013-12-31 00:00:00')
```

```
In [246]: pd.Timestamp('2014-01-01') + pd.offsets.MonthBegin(n=4)
Out[246]: Timestamp('2014-05-01 00:00:00')
```

```
In [247]: pd.Timestamp('2014-01-31') - pd.offsets.MonthBegin(n=4)
Out[247]: Timestamp('2013-10-01 00:00:00')
```

For the case when $n=0$, the date is not moved if on an anchor point, otherwise it is rolled forward to the next anchor point.

```
In [248]: pd.Timestamp('2014-01-02') + pd.offsets.MonthBegin(n=0)
Out[248]: Timestamp('2014-02-01 00:00:00')
```

```
In [249]: pd.Timestamp('2014-01-02') + pd.offsets.MonthEnd(n=0)
Out[249]: Timestamp('2014-01-31 00:00:00')
```

```
In [250]: pd.Timestamp('2014-01-01') + pd.offsets.MonthBegin(n=0)
Out[250]: Timestamp('2014-01-01 00:00:00')
```

```
In [251]: pd.Timestamp('2014-01-31') + pd.offsets.MonthEnd(n=0)
Out[251]: Timestamp('2014-01-31 00:00:00')
```

Holidays / holiday calendars

Holidays and calendars provide a simple way to define holiday rules to be used with `CustomBusinessDay` or in other analysis that requires a predefined set of holidays. The `AbstractHolidayCalendar` class provides all the necessary methods to return a list of holidays and only rules need to be defined in a specific holiday calendar class. Furthermore, the `start_date` and `end_date` class attributes determine over what date range holidays are generated. These should be overwritten on the `AbstractHolidayCalendar` class to have the range apply to all calendar subclasses. `USFederalHolidayCalendar` is the only calendar that exists and primarily serves as an example for developing other calendars.

For holidays that occur on fixed dates (e.g., US Memorial Day or July 4th) an observance rule determines when that holiday is observed if it falls on a weekend or some other non-observed day. Defined observance rules are:

Rule	Description
<code>nearest_workday</code>	move Saturday to Friday and Sunday to Monday
<code>sunday_to_monday</code>	move Sunday to following Monday
<code>next_monday_or_tuesday</code>	Saturday to Monday and Sunday/Monday to Tuesday
<code>previous_friday</code>	move Saturday and Sunday to previous Friday”
<code>next_monday</code>	move Saturday and Sunday to following Monday

An example of how holidays and holiday calendars are defined:

```
In [252]: from pandas.tseries.holiday import Holiday, USMemorialDay, \
.....:     AbstractHolidayCalendar, nearest_workday, MO
.....:

In [253]: class ExampleCalendar(AbstractHolidayCalendar):
.....:     rules = [
.....:         USMemorialDay,
.....:         Holiday('July 4th', month=7, day=4, observance=nearest_workday),
.....:         Holiday('Columbus Day', month=10, day=1,
.....:                 offset=pd.DateOffset(weekday=MO(2)))]

In [254]: cal = ExampleCalendar()

In [255]: cal.holidays(datetime.datetime(2012, 1, 1), datetime.datetime(2012, 12, 31))
Out[255]: DatetimeIndex(['2012-05-28', '2012-07-04', '2012-10-08'], dtype='datetime64[ns]', freq=None)
```

hint `weekday=MO(2)` is same as `2 * Week(weekday=2)`

Using this calendar, creating an index or doing offset arithmetic skips weekends and holidays (i.e., Memorial Day/July 4th). For example, the below defines a custom business day offset using the `ExampleCalendar`. Like any other offset, it can be used to create a `DatetimeIndex` or added to `datetime` or `Timestamp` objects.

```
In [256]: pd.date_range(start='7/1/2012', end='7/10/2012',
.....:             freq=pd.offsets.CDay(calendar=cal)).to_pydatetime()
.....:

Out[256]:
array([datetime.datetime(2012, 7, 2, 0, 0),
       datetime.datetime(2012, 7, 3, 0, 0),
       datetime.datetime(2012, 7, 5, 0, 0),
       datetime.datetime(2012, 7, 6, 0, 0),
       datetime.datetime(2012, 7, 9, 0, 0),
       datetime.datetime(2012, 7, 10, 0, 0)], dtype=object)
```

(continues on next page)

(continued from previous page)

```
In [257]: offset = pd.offsets.CustomBusinessDay(calendar=cal)

In [258]: datetime.datetime(2012, 5, 25) + offset
Out[258]: Timestamp('2012-05-29 00:00:00')

In [259]: datetime.datetime(2012, 7, 3) + offset
Out[259]: Timestamp('2012-07-05 00:00:00')

In [260]: datetime.datetime(2012, 7, 3) + 2 * offset
Out[260]: Timestamp('2012-07-06 00:00:00')

In [261]: datetime.datetime(2012, 7, 6) + offset
Out[261]: Timestamp('2012-07-09 00:00:00')
```

Ranges are defined by the `start_date` and `end_date` class attributes of `AbstractHolidayCalendar`. The defaults are shown below.

```
In [262]: AbstractHolidayCalendar.start_date
Out[262]: Timestamp('1970-01-01 00:00:00')

In [263]: AbstractHolidayCalendar.end_date
Out[263]: Timestamp('2200-12-31 00:00:00')
```

These dates can be overwritten by setting the attributes as `datetime/Timestamp/string`.

```
In [264]: AbstractHolidayCalendar.start_date = datetime.datetime(2012, 1, 1)

In [265]: AbstractHolidayCalendar.end_date = datetime.datetime(2012, 12, 31)

In [266]: cal.holidays()
Out[266]: DatetimeIndex(['2012-05-28', '2012-07-04', '2012-10-08'], dtype='datetime64[ns]', freq=None)
```

Every calendar class is accessible by name using the `get_calendar` function which returns a `holiday` class instance. Any imported calendar class will automatically be available by this function. Also, `HolidayCalendarFactory` provides an easy interface to create calendars that are combinations of calendars or calendars with additional rules.

```
In [267]: from pandas.tseries.holiday import get_calendar, HolidayCalendarFactory,
.....:     USLaborDay
.....:

In [268]: cal = get_calendar('ExampleCalendar')

In [269]: cal.rules
Out[269]:
[Holiday: Memorial Day (month=5, day=31, offset=<DateOffset: weekday=MO(-1)>),
 Holiday: July 4th (month=7, day=4, observance=<function nearest_workday at
 ↴0x7f6d4bfa3050>),
 Holiday: Columbus Day (month=10, day=1, offset=<DateOffset: weekday=MO(+2)>)]

In [270]: new_cal = HolidayCalendarFactory('NewExampleCalendar', cal, USLaborDay)

In [271]: new_cal.rules
Out[271]:
[Holiday: Labor Day (month=9, day=1, offset=<DateOffset: weekday=MO(+1)>),
```

(continues on next page)

(continued from previous page)

```
Holiday: Memorial Day (month=5, day=31, offset=<DateOffset: weekday=MO(-1)>),
Holiday: July 4th (month=7, day=4, observance=<function nearest_workday at
↪0x7f6d4bfa3050>),
Holiday: Columbus Day (month=10, day=1, offset=<DateOffset: weekday=MO(+2)>) ]
```

3.14.9 Time Series-Related Instance Methods

Shifting / lagging

One may want to *shift* or *lag* the values in a time series back and forward in time. The method for this is `shift()`, which is available on all of the pandas objects.

```
In [272]: ts = pd.Series(range(len(rng)), index=rng)

In [273]: ts = ts[:5]

In [274]: ts.shift(1)
Out[274]:
2012-01-01    NaN
2012-01-02    0.0
2012-01-03    1.0
Freq: D, dtype: float64
```

The `shift` method accepts an `freq` argument which can accept a `DateOffset` class or other `timedelta`-like object or also an *offset alias*:

```
In [275]: ts.shift(5, freq=pd.offsets.BDay())
Out[275]:
2012-01-06    0
2012-01-09    1
2012-01-10    2
Freq: B, dtype: int64

In [276]: ts.shift(5, freq='BM')
Out[276]:
2012-05-31    0
2012-05-31    1
2012-05-31    2
Freq: D, dtype: int64
```

Rather than changing the alignment of the data and the index, `DataFrame` and `Series` objects also have a `tshift()` convenience method that changes all the dates in the index by a specified number of offsets:

```
In [277]: ts.tshift(5, freq='D')
Out[277]:
2012-01-06    0
2012-01-07    1
2012-01-08    2
Freq: D, dtype: int64
```

Note that with `tshift`, the leading entry is no longer `NaN` because the data is not being realigned.

Frequency conversion

The primary function for changing frequencies is the `asfreq()` method. For a `DatetimeIndex`, this is basically just a thin, but convenient wrapper around `reindex()` which generates a `date_range` and calls `reindex`.

```
In [278]: dr = pd.date_range('1/1/2010', periods=3, freq=3 * pd.offsets.BDay())
In [279]: ts = pd.Series(np.random.randn(3), index=dr)
In [280]: ts
Out[280]:
2010-01-01    -0.014261
2010-01-06    -0.760069
2010-01-11     0.028879
Freq: B, dtype: float64

In [281]: ts.asfreq(pd.offsets.BDay())
Out[281]:
2010-01-01    -0.014261
2010-01-04      NaN
2010-01-05      NaN
2010-01-06    -0.760069
2010-01-07      NaN
2010-01-08      NaN
2010-01-11     0.028879
Freq: B, dtype: float64
```

`asfreq` provides a further convenience so you can specify an interpolation method for any gaps that may appear after the frequency conversion.

```
In [282]: ts.asfreq(pd.offsets.BDay(), method='pad')
Out[282]:
2010-01-01    -0.014261
2010-01-04    -0.014261
2010-01-05    -0.014261
2010-01-06    -0.760069
2010-01-07    -0.760069
2010-01-08    -0.760069
2010-01-11     0.028879
Freq: B, dtype: float64
```

Filling forward / backward

Related to `asfreq` and `reindex` is `fillna()`, which is documented in the [missing data section](#).

Converting to Python datetimes

`DatetimeIndex` can be converted to an array of Python native `datetime.datetime` objects using the `to_pydatetime` method.

3.14.10 Resampling

Pandas has a simple, powerful, and efficient functionality for performing resampling operations during frequency conversion (e.g., converting secondly data into 5-minute data). This is extremely common in, but not limited to, financial applications.

`resample()` is a time-based groupby, followed by a reduction method on each of its groups. See some [cookbook examples](#) for some advanced strategies.

The `resample()` method can be used directly from `DataFrameGroupBy` objects, see the [groupby docs](#).

Note: `.resample()` is similar to using a `rolling()` operation with a time-based offset, see a discussion [here](#).

Basics

```
In [283]: rng = pd.date_range('1/1/2012', periods=100, freq='S')
In [284]: ts = pd.Series(np.random.randint(0, 500, len(rng)), index=rng)
In [285]: ts.resample('5Min').sum()
Out[285]:
2012-01-01    25003
Freq: 5T, dtype: int64
```

The `resample` function is very flexible and allows you to specify many different parameters to control the frequency conversion and resampling operation.

Any function available via [dispatching](#) is available as a method of the returned object, including `sum`, `mean`, `std`, `sem`, `max`, `min`, `median`, `first`, `last`, `ohlc`:

```
In [286]: ts.resample('5Min').mean()
Out[286]:
2012-01-01    250.03
Freq: 5T, dtype: float64

In [287]: ts.resample('5Min').ohlc()
Out[287]:
      open   high   low  close
2012-01-01    114    499     0    381

In [288]: ts.resample('5Min').max()
Out[288]:
2012-01-01    499
Freq: 5T, dtype: int64
```

For downsampling, `closed` can be set to ‘left’ or ‘right’ to specify which end of the interval is closed:

```
In [289]: ts.resample('5Min', closed='right').mean()
Out[289]:
2011-12-31 23:55:00    114.00000
2012-01-01 00:00:00    251.40404
Freq: 5T, dtype: float64

In [290]: ts.resample('5Min', closed='left').mean()
Out[290]:
```

(continues on next page)

(continued from previous page)

```
2012-01-01    250.03
Freq: 5T, dtype: float64
```

Parameters like `label` and `loffset` are used to manipulate the resulting labels. `label` specifies whether the result is labeled with the beginning or the end of the interval. `loffset` performs a time adjustment on the output labels.

```
In [291]: ts.resample('5Min').mean() # by default label='left'
Out[291]:
2012-01-01    250.03
Freq: 5T, dtype: float64

In [292]: ts.resample('5Min', label='left').mean()
Out[292]:
2012-01-01    250.03
Freq: 5T, dtype: float64

In [293]: ts.resample('5Min', label='left', loffset='1s').mean()
Out[293]:
2012-01-01 00:00:01    250.03
dtype: float64
```

Warning: The default values for `label` and `closed` is '`left`' for all frequency offsets except for '`M`', '`A`', '`Q`', '`BM`', '`BA`', '`BQ`', and '`W`' which all have a default of '`right`'.

This might unintendedly lead to looking ahead, where the value for a later time is pulled back to a previous time as in the following example with the `BusinessDay` frequency:

```
In [294]: s = pd.date_range('2000-01-01', '2000-01-05').to_series()

In [295]: s.iloc[2] = pd.NaT

In [296]: s.dt.day_name()
Out[296]:
2000-01-01    Saturday
2000-01-02    Sunday
2000-01-03      NaN
2000-01-04    Tuesday
2000-01-05   Wednesday
Freq: D, dtype: object

# default: label='left', closed='left'
In [297]: s.resample('B').last().dt.day_name()
Out[297]:
1999-12-31    Sunday
2000-01-03      NaN
2000-01-04    Tuesday
2000-01-05   Wednesday
Freq: B, dtype: object
```

Notice how the value for Sunday got pulled back to the previous Friday. To get the behavior where the value for Sunday is pushed to Monday, use instead

```
In [298]: s.resample('B', label='right', closed='right').last().dt.day_name()
Out[298]:
2000-01-03    Sunday
2000-01-04    Tuesday
2000-01-05   Wednesday
Freq: B, dtype: object
```

The `axis` parameter can be set to 0 or 1 and allows you to resample the specified axis for a `DataFrame`.

`kind` can be set to ‘`timestamp`’ or ‘`period`’ to convert the resulting index to/from timestamp and time span representations. By default `resample` retains the input representation.

`convention` can be set to ‘`start`’ or ‘`end`’ when resampling period data (detail below). It specifies how low frequency periods are converted to higher frequency periods.

Upsampling

For upsampling, you can specify a way to upsample and the `limit` parameter to interpolate over the gaps that are created:

```
# from secondly to every 250 milliseconds
In [299]: ts[:2].resample('250L').asfreq()
Out[299]:
2012-01-01 00:00:00.000    114.0
2012-01-01 00:00:00.250      NaN
2012-01-01 00:00:00.500      NaN
2012-01-01 00:00:00.750      NaN
2012-01-01 00:00:01.000    119.0
Freq: 250L, dtype: float64

In [300]: ts[:2].resample('250L').ffill()
Out[300]:
2012-01-01 00:00:00.000    114
2012-01-01 00:00:00.250    114
2012-01-01 00:00:00.500    114
2012-01-01 00:00:00.750    114
2012-01-01 00:00:01.000    119
Freq: 250L, dtype: int64

In [301]: ts[:2].resample('250L').ffill(limit=2)
Out[301]:
2012-01-01 00:00:00.000    114.0
2012-01-01 00:00:00.250    114.0
2012-01-01 00:00:00.500    114.0
2012-01-01 00:00:00.750      NaN
2012-01-01 00:00:01.000    119.0
Freq: 250L, dtype: float64
```

Sparse resampling

Sparse timeseries are the ones where you have a lot fewer points relative to the amount of time you are looking to resample. Naively upsampling a sparse series can potentially generate lots of intermediate values. When you don’t want to use a method to fill these values, e.g. `fill_method` is `None`, then intermediate values will be filled with `NaN`.

Since `resample` is a time-based groupby, the following is a method to efficiently resample only the groups that are not all `NaN`.

```
In [302]: rng = pd.date_range('2014-1-1', periods=100, freq='D') + pd.Timedelta('1s')
```

```
In [303]: ts = pd.Series(range(100), index=rng)
```

If we want to resample to the full range of the series:

```
In [304]: ts.resample('3T').sum()
Out[304]:
2014-01-01 00:00:00    0
2014-01-01 00:03:00    0
2014-01-01 00:06:00    0
2014-01-01 00:09:00    0
2014-01-01 00:12:00    0
...
2014-04-09 23:48:00    0
2014-04-09 23:51:00    0
2014-04-09 23:54:00    0
2014-04-09 23:57:00    0
2014-04-10 00:00:00    99
Freq: 3T, Length: 47521, dtype: int64
```

We can instead only resample those groups where we have points as follows:

```
In [305]: from functools import partial
```

```
In [306]: from pandas.tseries.frequencies import to_offset
```

```
In [307]: def round(t, freq):
.....:     freq = to_offset(freq)
.....:     return pd.Timestamp((t.value // freq.delta.value) * freq.delta.value)
.....:
```

```
In [308]: ts.groupby(partial(round, freq='3T')).sum()
```

```
Out[308]:
2014-01-01    0
2014-01-02    1
2014-01-03    2
2014-01-04    3
2014-01-05    4
...
2014-04-06   95
2014-04-07   96
2014-04-08   97
2014-04-09   98
2014-04-10   99
Length: 100, dtype: int64
```

Aggregation

Similar to the *aggregating API*, *groupby API*, and the *window functions API*, a Resampler can be selectively resampled.

Resampling a DataFrame, the default will be to act on all columns with the same function.

```
In [309]: df = pd.DataFrame(np.random.randn(1000, 3),
.....:                               index=pd.date_range('1/1/2012', freq='S', periods=1000),
.....:                               columns=['A', 'B', 'C'])

In [310]: r = df.resample('3T')

In [311]: r.mean()
Out[311]:
          A         B         C
2012-01-01 00:00:00 -0.033781 -0.032439  0.024324
2012-01-01 00:03:00 -0.023499  0.121188  0.013790
2012-01-01 00:06:00 -0.038522  0.061784  0.022712
2012-01-01 00:09:00  0.015962  0.076245  0.028317
2012-01-01 00:12:00 -0.011113 -0.044745 -0.086097
2012-01-01 00:15:00 -0.008164 -0.148956 -0.025592
```

We can select a specific column or columns using standard getitem.

```
In [312]: r['A'].mean()
Out[312]:
2012-01-01 00:00:00    -0.033781
2012-01-01 00:03:00    -0.023499
2012-01-01 00:06:00    -0.038522
2012-01-01 00:09:00     0.015962
2012-01-01 00:12:00   -0.011113
2012-01-01 00:15:00   -0.008164
Freq: 3T, Name: A, dtype: float64

In [313]: r[['A', 'B']].mean()
Out[313]:
          A         B
2012-01-01 00:00:00 -0.033781 -0.032439
2012-01-01 00:03:00 -0.023499  0.121188
2012-01-01 00:06:00 -0.038522  0.061784
2012-01-01 00:09:00  0.015962  0.076245
2012-01-01 00:12:00 -0.011113 -0.044745
2012-01-01 00:15:00 -0.008164 -0.148956
```

You can pass a list or dict of functions to do aggregation with, outputting a DataFrame:

```
In [314]: r['A'].agg([np.sum, np.mean, np.std])
Out[314]:
           sum        mean        std
2012-01-01 00:00:00 -6.080538 -0.033781  1.063125
2012-01-01 00:03:00 -4.229885 -0.023499  0.967564
2012-01-01 00:06:00 -6.934007 -0.038522  1.026984
2012-01-01 00:09:00  2.873238  0.015962  0.961662
2012-01-01 00:12:00 -2.000302 -0.011113  0.951884
2012-01-01 00:15:00 -0.816366 -0.008164  0.879981
```

On a resampled DataFrame, you can pass a list of functions to apply to each column, which produces an aggregated

result with a hierarchical index:

```
In [315]: r.agg([np.sum, np.mean])
Out[315]:
          A                  B                  C
          sum      mean      sum      mean      sum      mean
2012-01-01 00:00:00 -6.080538 -0.033781 -5.838938 -0.032439 4.378241 0.024324
2012-01-01 00:03:00 -4.229885 -0.023499 21.813827 0.121188 2.482252 0.013790
2012-01-01 00:06:00 -6.934007 -0.038522 11.121162 0.061784 4.088109 0.022712
2012-01-01 00:09:00  2.873238  0.015962 13.724028 0.076245 5.097129 0.028317
2012-01-01 00:12:00 -2.000302 -0.011113 -8.054085 -0.044745 -15.497435 -0.086097
2012-01-01 00:15:00 -0.816366 -0.008164 -14.895550 -0.148956 -2.559218 -0.025592
```

By passing a dict to `aggregate` you can apply a different aggregation to the columns of a DataFrame:

```
In [316]: r.agg({'A': np.sum,
.....:     'B': lambda x: np.std(x, ddof=1)})
.....:
Out[316]:
          A      B
2012-01-01 00:00:00 -6.080538 0.929504
2012-01-01 00:03:00 -4.229885 0.945142
2012-01-01 00:06:00 -6.934007 0.992286
2012-01-01 00:09:00  2.873238 0.990177
2012-01-01 00:12:00 -2.000302 0.976255
2012-01-01 00:15:00 -0.816366 1.037785
```

The function names can also be strings. In order for a string to be valid it must be implemented on the resampled object:

```
In [317]: r.agg({'A': 'sum', 'B': 'std'})
Out[317]:
          A      B
2012-01-01 00:00:00 -6.080538 0.929504
2012-01-01 00:03:00 -4.229885 0.945142
2012-01-01 00:06:00 -6.934007 0.992286
2012-01-01 00:09:00  2.873238 0.990177
2012-01-01 00:12:00 -2.000302 0.976255
2012-01-01 00:15:00 -0.816366 1.037785
```

Furthermore, you can also specify multiple aggregation functions for each column separately.

```
In [318]: r.agg({'A': ['sum', 'std'], 'B': ['mean', 'std']})
Out[318]:
          A                  B
          sum      std      mean      std
2012-01-01 00:00:00 -6.080538 1.063125 -0.032439 0.929504
2012-01-01 00:03:00 -4.229885 0.967564 0.121188 0.945142
2012-01-01 00:06:00 -6.934007 1.026984 0.061784 0.992286
2012-01-01 00:09:00  2.873238 0.961662 0.076245 0.990177
2012-01-01 00:12:00 -2.000302 0.951884 -0.044745 0.976255
2012-01-01 00:15:00 -0.816366 0.879981 -0.148956 1.037785
```

If a DataFrame does not have a datetimelike index, but instead you want to resample based on datetimelike column in the frame, it can passed to the `on` keyword.

```
In [319]: df = pd.DataFrame({'date': pd.date_range('2015-01-01', freq='W', periods=5),
.....:     'a': np.arange(5)},
```

(continues on next page)

(continued from previous page)

```
.....: index=pd.MultiIndex.from_arrays([
.....: [1, 2, 3, 4, 5],
.....: pd.date_range('2015-01-01', freq='W', periods=5)],
.....: names=['v', 'd']))
.....:

In [320]: df
Out[320]:
          date   a
v d
1 2015-01-04 2015-01-04  0
2 2015-01-11 2015-01-11  1
3 2015-01-18 2015-01-18  2
4 2015-01-25 2015-01-25  3
5 2015-02-01 2015-02-01  4

In [321]: df.resample('M', on='date').sum()
Out[321]:
          a
date
2015-01-31  6
2015-02-28  4
```

Similarly, if you instead want to resample by a datetimelike level of `MultiIndex`, its name or location can be passed to the `level` keyword.

```
In [322]: df.resample('M', level='d').sum()
Out[322]:
          a
d
2015-01-31    6
2015-02-28    4
```

Iterating through groups

With the `Resampler` object in hand, iterating through the grouped data is very natural and functions similarly to `itertools.groupby()`:

(continues on next page)

(continued from previous page)

```
.....
Group: 2017-01-01 00:00:00
-----
2017-01-01 00:00:00    0
2017-01-01 00:30:00    1
2017-01-01 00:31:00    2
dtype: int64

Group: 2017-01-01 01:00:00
-----
2017-01-01 01:00:00    3
dtype: int64

Group: 2017-01-01 02:00:00
-----
Series([], dtype: int64)

Group: 2017-01-01 03:00:00
-----
2017-01-01 03:00:00    4
2017-01-01 03:05:00    5
dtype: int64
```

See [Iterating through groups](#) or `Resampler.__iter__` for more.

3.14.11 Time span representation

Regular intervals of time are represented by `Period` objects in pandas while sequences of `Period` objects are collected in a `PeriodIndex`, which can be created with the convenience function `period_range`.

Period

A `Period` represents a span of time (e.g., a day, a month, a quarter, etc). You can specify the span via `freq` keyword using a frequency alias like below. Because `freq` represents a span of `Period`, it cannot be negative like “-3D”.

```
In [326]: pd.Period('2012', freq='A-DEC')
Out[326]: Period('2012', 'A-DEC')

In [327]: pd.Period('2012-1-1', freq='D')
Out[327]: Period('2012-01-01', 'D')

In [328]: pd.Period('2012-1-1 19:00', freq='H')
Out[328]: Period('2012-01-01 19:00', 'H')

In [329]: pd.Period('2012-1-1 19:00', freq='5H')
Out[329]: Period('2012-01-01 19:00', '5H')
```

Adding and subtracting integers from periods shifts the period by its own frequency. Arithmetic is not allowed between `Period` with different `freq` (span).

```
In [330]: p = pd.Period('2012', freq='A-DEC')

In [331]: p + 1
Out[331]: Period('2013', 'A-DEC')
```

(continues on next page)

(continued from previous page)

```
In [332]: p = 3
Out[332]: Period('2009', 'A-DEC')

In [333]: p = pd.Period('2012-01', freq='2M')

In [334]: p + 2
Out[334]: Period('2012-05', '2M')

In [335]: p - 1
Out[335]: Period('2011-11', '2M')

In [336]: p == pd.Period('2012-01', freq='3M')
-----
IncompatibleFrequency Traceback (most recent call last)
<ipython-input-336-4b67dc0b596c> in <module>
----> 1 p == pd.Period('2012-01', freq='3M')

IncompatibleFrequency: Input has different freq=3M from Period(freq=2M)
```

If `Period` `freq` is daily or higher (D, H, T, S, L, U, N), offsets and `timedelta`-like can be added if the result can have the same freq. Otherwise, `ValueError` will be raised.

```
In [337]: p = pd.Period('2014-07-01 09:00', freq='H')

In [338]: p + pd.offsets.Hour(2)
Out[338]: Period('2014-07-01 11:00', 'H')

In [339]: p + datetime.timedelta(minutes=120)
Out[339]: Period('2014-07-01 11:00', 'H')

In [340]: p + np.timedelta64(7200, 's')
Out[340]: Period('2014-07-01 11:00', 'H')
```

```
In [1]: p + pd.offsets.Minute(5)
Traceback
...
ValueError: Input has different freq from Period(freq=H)
```

If `Period` has other frequencies, only the same offsets can be added. Otherwise, `ValueError` will be raised.

```
In [341]: p = pd.Period('2014-07', freq='M')

In [342]: p + pd.offsets.MonthEnd(3)
Out[342]: Period('2014-10', 'M')
```

```
In [1]: p + pd.offsets.MonthBegin(3)
Traceback
...
ValueError: Input has different freq from Period(freq=M)
```

Taking the difference of `Period` instances with the same frequency will return the number of frequency units between them:

```
In [343]: pd.Period('2012', freq='A-DEC') - pd.Period('2002', freq='A-DEC')
Out[343]: <10 * YearEnds: month=12>
```

PeriodIndex and period_range

Regular sequences of Period objects can be collected in a PeriodIndex, which can be constructed using the period_range convenience function:

```
In [344]: prng = pd.period_range('1/1/2011', '1/1/2012', freq='M')

In [345]: prng
Out[345]:
PeriodIndex(['2011-01', '2011-02', '2011-03', '2011-04', '2011-05', '2011-06',
            '2011-07', '2011-08', '2011-09', '2011-10', '2011-11', '2011-12',
            '2012-01'],
            dtype='period[M]', freq='M')
```

The PeriodIndex constructor can also be used directly:

```
In [346]: pd.PeriodIndex(['2011-1', '2011-2', '2011-3'], freq='M')
Out[346]: PeriodIndex(['2011-01', '2011-02', '2011-03'], dtype='period[M]', freq='M')
```

Passing multiplied frequency outputs a sequence of Period which has multiplied span.

```
In [347]: pd.period_range(start='2014-01', freq='3M', periods=4)
Out[347]: PeriodIndex(['2014-01', '2014-04', '2014-07', '2014-10'], dtype='period[3M]
˓→', freq='3M')
```

If start or end are Period objects, they will be used as anchor endpoints for a PeriodIndex with frequency matching that of the PeriodIndex constructor.

```
In [348]: pd.period_range(start=pd.Period('2017Q1', freq='Q'),
.....:                     end=pd.Period('2017Q2', freq='Q'), freq='M')
.....:
Out[348]: PeriodIndex(['2017-03', '2017-04', '2017-05', '2017-06'], dtype='period[M]',
˓→ freq='M')
```

Just like DatetimeIndex, a PeriodIndex can also be used to index pandas objects:

```
In [349]: ps = pd.Series(np.random.randn(len(prng)), prng)

In [350]: ps
Out[350]:
2011-01    0.818145
2011-02    0.267439
2011-03   -0.133309
2011-04    0.662254
2011-05   -0.688393
2011-06   -0.731718
2011-07   -1.190946
2011-08   -1.889384
2011-09    0.171033
2011-10    0.368582
2011-11    0.356459
2011-12    0.556248
```

(continues on next page)

(continued from previous page)

```
2012-01    -0.148709
Freq: M, dtype: float64
```

PeriodIndex supports addition and subtraction with the same rule as Period.

```
In [351]: idx = pd.period_range('2014-07-01 09:00', periods=5, freq='H')
In [352]: idx
Out[352]:
PeriodIndex(['2014-07-01 09:00', '2014-07-01 10:00', '2014-07-01 11:00',
             '2014-07-01 12:00', '2014-07-01 13:00'],
            dtype='period[H]', freq='H')

In [353]: idx + pd.offsets.Hour(2)
Out[353]:
PeriodIndex(['2014-07-01 11:00', '2014-07-01 12:00', '2014-07-01 13:00',
             '2014-07-01 14:00', '2014-07-01 15:00'],
            dtype='period[H]', freq='H')

In [354]: idx = pd.period_range('2014-07', periods=5, freq='M')
In [355]: idx
Out[355]: PeriodIndex(['2014-07', '2014-08', '2014-09', '2014-10', '2014-11'],
                      dtype='period[M]', freq='M')

In [356]: idx + pd.offsets.MonthEnd(3)
Out[356]: PeriodIndex(['2014-10', '2014-11', '2014-12', '2015-01', '2015-02'],
                      dtype='period[M]', freq='M')
```

PeriodIndex has its own dtype named period, refer to *Period Dtypes*.

Period dtypes

PeriodIndex has a custom period dtype. This is a pandas extension dtype similar to the *timezone aware dtype* (datetime64[ns, tz]).

The period dtype holds the freq attribute and is represented with period[freq] like period[D] or period[M], using *frequency strings*.

```
In [357]: pi = pd.period_range('2016-01-01', periods=3, freq='M')
In [358]: pi
Out[358]: PeriodIndex(['2016-01', '2016-02', '2016-03'],
                      dtype='period[M]', freq='M')

In [359]: pi.dtype
Out[359]: period[M]
```

The period dtype can be used in .astype(...). It allows one to change the freq of a PeriodIndex like .asfreq() and convert a DatetimeIndex to PeriodIndex like to_period():

```
# change monthly freq to daily freq
In [360]: pi.astype('period[D]')
Out[360]: PeriodIndex(['2016-01-31', '2016-02-29', '2016-03-31'],
                      dtype='period[D]', freq='D')
```

(continues on next page)

(continued from previous page)

```
# convert to DatetimeIndex
In [361]: pi.astype('datetime64[ns]')
Out[361]: DatetimeIndex(['2016-01-01', '2016-02-01', '2016-03-01'], dtype='datetime64[ns]', freq='MS')

# convert to PeriodIndex
In [362]: dti = pd.date_range('2011-01-01', freq='M', periods=3)

In [363]: dti
Out[363]: DatetimeIndex(['2011-01-31', '2011-02-28', '2011-03-31'], dtype='datetime64[ns]', freq='M')

In [364]: dti.astype('period[M]')
Out[364]: PeriodIndex(['2011-01', '2011-02', '2011-03'], dtype='period[M]', freq='M')
```

PeriodIndex partial string indexing

You can pass in dates and strings to Series and DataFrame with PeriodIndex, in the same manner as DatetimeIndex. For details, refer to [DatetimeIndex Partial String Indexing](#).

```
In [365]: ps['2011-01']
Out[365]: 0.8181454127659131

In [366]: ps[datetime.datetime(2011, 12, 25):]
Out[366]:
2011-12    0.556248
2012-01   -0.148709
Freq: M, dtype: float64

In [367]: ps['10/31/2011':'12/31/2011']
Out[367]:
2011-10    0.368582
2011-11    0.356459
2011-12    0.556248
Freq: M, dtype: float64
```

Passing a string representing a lower frequency than PeriodIndex returns partial sliced data.

```
In [368]: ps['2011']
Out[368]:
2011-01    0.818145
2011-02    0.267439
2011-03   -0.133309
2011-04    0.662254
2011-05   -0.688393
2011-06   -0.731718
2011-07   -1.190946
2011-08   -1.889384
2011-09    0.171033
2011-10    0.368582
2011-11    0.356459
2011-12    0.556248
Freq: M, dtype: float64

In [369]: dfp = pd.DataFrame(np.random.randn(600, 1),
```

(continues on next page)

(continued from previous page)

```

.....
.....:           columns=['A'],

```

Frequency conversion and resampling with PeriodIndex

The frequency of `Period` and `PeriodIndex` can be converted via the `asfreq` method. Let's start with the fiscal year 2011, ending in December:

```
In [373]: p = pd.Period('2011', freq='A-DEC')

In [374]: p
Out[374]: Period('2011', 'A-DEC')
```

We can convert it to a monthly frequency. Using the `how` parameter, we can specify whether to return the starting or ending month:

```
In [375]: p.asfreq('M', how='start')
Out[375]: Period('2011-01', 'M')

In [376]: p.asfreq('M', how='end')
Out[376]: Period('2011-12', 'M')
```

The shorthands ‘s’ and ‘e’ are provided for convenience:

```
In [377]: p.asfreq('M', 's')
Out[377]: Period('2011-01', 'M')

In [378]: p.asfreq('M', 'e')
Out[378]: Period('2011-12', 'M')
```

Converting to a “super-period” (e.g., annual frequency is a super-period of quarterly frequency) automatically returns the super-period that includes the input period:

```
In [379]: p = pd.Period('2011-12', freq='M')

In [380]: p.asfreq('A-NOV')
Out[380]: Period('2012', 'A-NOV')
```

Note that since we converted to an annual frequency that ends the year in November, the monthly period of December 2011 is actually in the 2012 A-NOV period.

Period conversions with anchored frequencies are particularly useful for working with various quarterly data common to economics, business, and other fields. Many organizations define quarters relative to the month in which their fiscal year starts and ends. Thus, first quarter of 2011 could start in 2010 or a few months into 2011. Via anchored frequencies, pandas works for all quarterly frequencies Q-JAN through Q-DEC.

Q-DEC define regular calendar quarters:

```
In [381]: p = pd.Period('2012Q1', freq='Q-DEC')

In [382]: p.asfreq('D', 's')
Out[382]: Period('2012-01-01', 'D')

In [383]: p.asfreq('D', 'e')
Out[383]: Period('2012-03-31', 'D')
```

Q-MAR defines fiscal year end in March:

```
In [384]: p = pd.Period('2011Q4', freq='Q-MAR')

In [385]: p.asfreq('D', 's')
```

(continues on next page)

(continued from previous page)

```
Out[385]: Period('2011-01-01', 'D')

In [386]: p.asfreq('D', 'e')
Out[386]: Period('2011-03-31', 'D')
```

3.14.12 Converting between representations

Timestamped data can be converted to PeriodIndex-ed data using `to_period` and vice-versa using `to_timestamp`:

```
In [387]: rng = pd.date_range('1/1/2012', periods=5, freq='M')

In [388]: ts = pd.Series(np.random.randn(len(rng)), index=rng)

In [389]: ts
Out[389]:
2012-01-31    0.886762
2012-02-29    0.034219
2012-03-31   -0.120191
2012-04-30   -1.448144
2012-05-31   -0.316413
Freq: M, dtype: float64

In [390]: ps = ts.to_period()

In [391]: ps
Out[391]:
2012-01    0.886762
2012-02    0.034219
2012-03   -0.120191
2012-04   -1.448144
2012-05   -0.316413
Freq: M, dtype: float64

In [392]: ps.to_timestamp()
Out[392]:
2012-01-01    0.886762
2012-02-01    0.034219
2012-03-01   -0.120191
2012-04-01   -1.448144
2012-05-01   -0.316413
Freq: MS, dtype: float64
```

Remember that ‘s’ and ‘e’ can be used to return the timestamps at the start or end of the period:

```
In [393]: ps.to_timestamp('D', how='s')
Out[393]:
2012-01-01    0.886762
2012-02-01    0.034219
2012-03-01   -0.120191
2012-04-01   -1.448144
2012-05-01   -0.316413
Freq: MS, dtype: float64
```

Converting between period and timestamp enables some convenient arithmetic functions to be used. In the following

example, we convert a quarterly frequency with year ending in November to 9am of the end of the month following the quarter end:

```
In [394]: prng = pd.period_range('1990Q1', '2000Q4', freq='Q-NOV')

In [395]: ts = pd.Series(np.random.randn(len(prng)), prng)

In [396]: ts.index = (prng.asfreq('M', 'e') + 1).asfreq('H', 's') + 9

In [397]: ts.head()
Out[397]:
1990-03-01 09:00    1.136089
1990-06-01 09:00    0.413044
1990-09-01 09:00   -0.815750
1990-12-01 09:00    0.473114
1991-03-01 09:00   -0.242094
Freq: H, dtype: float64
```

3.14.13 Representing out-of-bounds spans

If you have data that is outside of the `Timestamp` bounds, see [Timestamp limitations](#), then you can use a `PeriodIndex` and/or `Series` of `Periods` to do computations.

```
In [398]: span = pd.period_range('1215-01-01', '1381-01-01', freq='D')

In [399]: span
Out[399]:
PeriodIndex(['1215-01-01', '1215-01-02', '1215-01-03', '1215-01-04',
             '1215-01-05', '1215-01-06', '1215-01-07', '1215-01-08',
             '1215-01-09', '1215-01-10',
             ...
             '1380-12-23', '1380-12-24', '1380-12-25', '1380-12-26',
             '1380-12-27', '1380-12-28', '1380-12-29', '1380-12-30',
             '1380-12-31', '1381-01-01'],
            dtype='period[D]', length=60632, freq='D')
```

To convert from an `int64` based YYYYMMDD representation.

```
In [400]: s = pd.Series([20121231, 20141130, 99991231])

In [401]: s
Out[401]:
0    20121231
1    20141130
2    99991231
dtype: int64

In [402]: def conv(x):
.....:     return pd.Period(year=x // 10000, month=x // 100 % 100,
.....:                         day=x % 100, freq='D')
.....:

In [403]: s.apply(conv)
Out[403]:
0    2012-12-31
1    2014-11-30
```

(continues on next page)

(continued from previous page)

```
2    9999-12-31  
dtype: period[D]
```

```
In [404]: s.apply(conv) [2]  
Out[404]: Period('9999-12-31', 'D')
```

These can easily be converted to a PeriodIndex:

```
In [405]: span = pd.PeriodIndex(s.apply(conv))  
  
In [406]: span  
Out[406]: PeriodIndex(['2012-12-31', '2014-11-30', '9999-12-31'], dtype='period[D]',  
freq='D')
```

3.14.14 Time zone handling

pandas provides rich support for working with timestamps in different time zones using the `pytz` and `dateutil` libraries or class:`datetime.timezone` objects from the standard library.

Working with time zones

By default, pandas objects are time zone unaware:

```
In [407]: rng = pd.date_range('3/6/2012 00:00', periods=15, freq='D')  
  
In [408]: rng.tz is None  
Out[408]: True
```

To localize these dates to a time zone (assign a particular time zone to a naive date), you can use the `tz_localize` method or the `tz` keyword argument in `date_range()`, `Timestamp`, or `DatetimeIndex`. You can either pass `pytz` or `dateutil` time zone objects or Olson time zone database strings. Olson time zone strings will return `pytz` time zone objects by default. To return `dateutil` time zone objects, append `dateutil/` before the string.

- In `pytz` you can find a list of common (and less common) time zones using `from pytz import common_timezones, all_timezones`.
- `dateutil` uses the OS time zones so there isn't a fixed list available. For common zones, the names are the same as `pytz`.

```
In [409]: import dateutil  
  
# pytz  
In [410]: rng_pytz = pd.date_range('3/6/2012 00:00', periods=3, freq='D',  
.....:                         tz='Europe/London')  
.....:  
  
In [411]: rng_pytz.tz  
Out[411]: <DstTzInfo 'Europe/London' LMT-1 day, 23:59:00 STD>  
  
# dateutil  
In [412]: rng_dateutil = pd.date_range('3/6/2012 00:00', periods=3, freq='D')  
  
In [413]: rng_dateutil = rng_dateutil.tz_localize('dateutil/Europe/London')
```

(continues on next page)

(continued from previous page)

```
In [414]: rng_dateutil.tz
Out[414]: tzfile('/usr/share/zoneinfo/Europe/London')

# dateutil - utc special case
In [415]: rng_utc = pd.date_range('3/6/2012 00:00', periods=3, freq='D',
.....:                      tz=dateutil.tz.tzutc())
.....:

In [416]: rng_utc.tz
Out[416]: tzutc()
```

New in version 0.25.0.

```
# datetime.timezone
In [417]: rng_utc = pd.date_range('3/6/2012 00:00', periods=3, freq='D',
.....:                      tz=datetime.timezone.utc)
.....:

In [418]: rng_utc.tz
Out[418]: datetime.timezone.utc
```

Note that the UTC time zone is a special case in `dateutil` and should be constructed explicitly as an instance of `dateutil.tz.tzutc`. You can also construct other time zones objects explicitly first.

```
In [419]: import pytz

# pytz
In [420]: tz_pytz = pytz.timezone('Europe/London')

In [421]: rng_pytz = pd.date_range('3/6/2012 00:00', periods=3, freq='D')

In [422]: rng_pytz = rng_pytz.tz_localize(tz_pytz)

In [423]: rng_pytz.tz == tz_pytz
Out[423]: True

# dateutil
In [424]: tz_dateutil = dateutil.tz.gettz('Europe/London')

In [425]: rng_dateutil = pd.date_range('3/6/2012 00:00', periods=3, freq='D',
.....:                      tz=tz_dateutil)
.....:

In [426]: rng_dateutil.tz == tz_dateutil
Out[426]: True
```

To convert a time zone aware pandas object from one time zone to another, you can use the `tz_convert` method.

```
In [427]: rng_pytz.tz_convert('US/Eastern')
Out[427]:
DatetimeIndex(['2012-03-05 19:00:00-05:00', '2012-03-06 19:00:00-05:00',
               '2012-03-07 19:00:00-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq='D')
```

Note: When using `pytz` time zones, `DatetimeIndex` will construct a different time zone object than a `Timestamp` for the same time zone input. A `DatetimeIndex` can hold a collection of `Timestamp` objects

that may have different UTC offsets and cannot be succinctly represented by one `pytz` time zone instance while one `Timestamp` represents one point in time with a specific UTC offset.

```
In [428]: dti = pd.date_range('2019-01-01', periods=3, freq='D', tz='US/Pacific')

In [429]: dti.tz
Out[429]: <DstTzInfo 'US/Pacific' LMT-1 day, 16:07:00 STD>

In [430]: ts = pd.Timestamp('2019-01-01', tz='US/Pacific')

In [431]: ts.tz
Out[431]: <DstTzInfo 'US/Pacific' PST-1 day, 16:00:00 STD>
```

Warning: Be wary of conversions between libraries. For some time zones, `pytz` and `dateutil` have different definitions of the zone. This is more of a problem for unusual time zones than for ‘standard’ zones like US/Eastern.

Warning: Be aware that a time zone definition across versions of time zone libraries may not be considered equal. This may cause problems when working with stored data that is localized using one version and operated on with a different version. See [here](#) for how to handle such a situation.

Warning: For `pytz` time zones, it is incorrect to pass a time zone object directly into the `datetime.datetime` constructor (e.g., `datetime.datetime(2011, 1, 1, tz=pytz.timezone('US/Eastern'))`). Instead, the datetime needs to be localized using the `localize` method on the `pytz` time zone object.

Under the hood, all timestamps are stored in UTC. Values from a time zone aware `DatetimeIndex` or `Timestamp` will have their fields (day, hour, minute, etc.) localized to the time zone. However, timestamps with the same UTC value are still considered to be equal even if they are in different time zones:

```
In [432]: rng_eastern = rng_utc.tz_convert('US/Eastern')

In [433]: rng_berlin = rng_utc.tz_convert('Europe/Berlin')

In [434]: rng_eastern[2]
Out[434]: Timestamp('2012-03-07 19:00:00-0500', tz='US/Eastern', freq='D')

In [435]: rng_berlin[2]
Out[435]: Timestamp('2012-03-08 01:00:00+0100', tz='Europe/Berlin', freq='D')

In [436]: rng_eastern[2] == rng_berlin[2]
Out[436]: True
```

Operations between `Series` in different time zones will yield UTC `Series`, aligning the data on the UTC timestamps:

```
In [437]: ts_utc = pd.Series(range(3), pd.date_range('20130101', periods=3, tz='UTC'))

In [438]: eastern = ts_utc.tz_convert('US/Eastern')
```

(continues on next page)

(continued from previous page)

```
In [439]: berlin = ts_utc.tz_convert('Europe/Berlin')

In [440]: result = eastern + berlin

In [441]: result
Out[441]:
2013-01-01 00:00:00+00:00    0
2013-01-02 00:00:00+00:00    2
2013-01-03 00:00:00+00:00    4
Freq: D, dtype: int64

In [442]: result.index
Out[442]:
DatetimeIndex(['2013-01-01 00:00:00+00:00', '2013-01-02 00:00:00+00:00',
               '2013-01-03 00:00:00+00:00'],
              dtype='datetime64[ns, UTC]', freq='D')
```

To remove time zone information, use `tz_localize(None)` or `tz_convert(None).tz_localize(None)`. `tz_localize(None)` will remove the time zone yielding the local time representation. `tz_convert(None)` will remove the time zone after converting to UTC time.

```
In [443]: didx = pd.date_range(start='2014-08-01 09:00', freq='H',
.....:                               periods=3, tz='US/Eastern')
.....:

In [444]: didx
Out[444]:
DatetimeIndex(['2014-08-01 09:00:00-04:00', '2014-08-01 10:00:00-04:00',
               '2014-08-01 11:00:00-04:00'],
              dtype='datetime64[ns, US/Eastern]', freq='H')

In [445]: didx.tz_localize(None)
Out[445]:
DatetimeIndex(['2014-08-01 09:00:00', '2014-08-01 10:00:00',
               '2014-08-01 11:00:00'],
              dtype='datetime64[ns]', freq='H')

In [446]: didx.tz_convert(None)
Out[446]:
DatetimeIndex(['2014-08-01 13:00:00', '2014-08-01 14:00:00',
               '2014-08-01 15:00:00'],
              dtype='datetime64[ns]', freq='H')

# tz_convert(None) is identical to tz_convert('UTC').tz_localize(None)
In [447]: didx.tz_convert('UTC').tz_localize(None)
Out[447]:
DatetimeIndex(['2014-08-01 13:00:00', '2014-08-01 14:00:00',
               '2014-08-01 15:00:00'],
              dtype='datetime64[ns]', freq='H')
```

Ambiguous times when localizing

`tz_localize` may not be able to determine the UTC offset of a timestamp because daylight savings time (DST) in a local time zone causes some times to occur twice within one day (“clocks fall back”). The following options are available:

- `'raise'`: Raises a `pytz.AmbiguousTimeError` (the default behavior)
- `'infer'`: Attempt to determine the correct offset base on the monotonicity of the timestamps
- `'NaT'`: Replaces ambiguous times with `NaT`
- `bool`: `True` represents a DST time, `False` represents non-DST time. An array-like of `bool` values is supported for a sequence of times.

```
In [448]: rng_hourly = pd.DatetimeIndex(['11/06/2011 00:00', '11/06/2011 01:00',
.....:                               '11/06/2011 01:00', '11/06/2011 02:00'])
.....:
```

This will fail as there are ambiguous times ('11/06/2011 01:00')

```
In [2]: rng_hourly.tz_localize('US/Eastern')
AmbiguousTimeError: Cannot infer dst time from Timestamp('2011-11-06 01:00:00'), try_
→using the 'ambiguous' argument
```

Handle these ambiguous times by specifying the following.

```
In [449]: rng_hourly.tz_localize('US/Eastern', ambiguous='infer')
Out[449]:
DatetimeIndex(['2011-11-06 00:00:00-04:00', '2011-11-06 01:00:00-04:00',
               '2011-11-06 01:00:00-05:00', '2011-11-06 02:00:00-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq=None)

In [450]: rng_hourly.tz_localize('US/Eastern', ambiguous='NaT')
Out[450]:
DatetimeIndex(['2011-11-06 00:00:00-04:00', 'NaT', 'NaT',
               '2011-11-06 02:00:00-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq=None)

In [451]: rng_hourly.tz_localize('US/Eastern', ambiguous=[True, True, False, False])
Out[451]:
DatetimeIndex(['2011-11-06 00:00:00-04:00', '2011-11-06 01:00:00-04:00',
               '2011-11-06 01:00:00-05:00', '2011-11-06 02:00:00-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq=None)
```

Nonexistent times when localizing

A DST transition may also shift the local time ahead by 1 hour creating nonexistent local times (“clocks spring forward”). The behavior of localizing a timeseries with nonexistent times can be controlled by the `nonexistent` argument. The following options are available:

- `'raise'`: Raises a `pytz.NonExistentTimeError` (the default behavior)
- `'NaT'`: Replaces nonexistent times with `NaT`
- `'shift_forward'`: Shifts nonexistent times forward to the closest real time
- `'shift_backward'`: Shifts nonexistent times backward to the closest real time
- `timedelta` object: Shifts nonexistent times by the `timedelta` duration

```
In [452]: dti = pd.date_range(start='2015-03-29 02:30:00', periods=3, freq='H')
# 2:30 is a nonexistent time
```

Localization of nonexistent times will raise an error by default.

```
In [2]: dti.tz_localize('Europe/Warsaw')
NonExistentTimeError: 2015-03-29 02:30:00
```

Transform nonexistent times to NaT or shift the times.

```
In [453]: dti
Out[453]:
DatetimeIndex(['2015-03-29 02:30:00', '2015-03-29 03:30:00',
               '2015-03-29 04:30:00'],
              dtype='datetime64[ns]', freq='H')

In [454]: dti.tz_localize('Europe/Warsaw', nonexistent='shift_forward')
Out[454]:
DatetimeIndex(['2015-03-29 03:00:00+02:00', '2015-03-29 03:30:00+02:00',
               '2015-03-29 04:30:00+02:00'],
              dtype='datetime64[ns, Europe/Warsaw]', freq='H')

In [455]: dti.tz_localize('Europe/Warsaw', nonexistent='shift_backward')
Out[455]:
DatetimeIndex(['2015-03-29 01:59:59.999999999+01:00',
               '2015-03-29 03:30:00+02:00',
               '2015-03-29 04:30:00+02:00'],
              dtype='datetime64[ns, Europe/Warsaw]', freq='H')

In [456]: dti.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta(1, unit='H'))
Out[456]:
DatetimeIndex(['2015-03-29 03:30:00+02:00', '2015-03-29 03:30:00+02:00',
               '2015-03-29 04:30:00+02:00'],
              dtype='datetime64[ns, Europe/Warsaw]', freq='H')

In [457]: dti.tz_localize('Europe/Warsaw', nonexistent='NaT')
Out[457]:
DatetimeIndex(['NaT', '2015-03-29 03:30:00+02:00',
               '2015-03-29 04:30:00+02:00'],
              dtype='datetime64[ns, Europe/Warsaw]', freq='H')
```

Time zone series operations

A Series with time zone **naive** values is represented with a dtype of datetime64 [ns].

```
In [458]: s_naive = pd.Series(pd.date_range('20130101', periods=3))

In [459]: s_naive
Out[459]:
0    2013-01-01
1    2013-01-02
2    2013-01-03
dtype: datetime64[ns]
```

A Series with a time zone **aware** values is represented with a dtype of datetime64 [ns, tz] where tz is the time zone

```
In [460]: s_aware = pd.Series(pd.date_range('20130101', periods=3, tz='US/Eastern'))
```

```
In [461]: s_aware
```

```
Out[461]:
```

```
0    2013-01-01 00:00:00-05:00  
1    2013-01-02 00:00:00-05:00  
2    2013-01-03 00:00:00-05:00  
dtype: datetime64[ns, US/Eastern]
```

Both of these Series time zone information can be manipulated via the `.dt` accessor, see [the `dt` accessor section](#).

For example, to localize and convert a naive stamp to time zone aware.

```
In [462]: s_naive.dt.tz_localize('UTC').dt.tz_convert('US/Eastern')
```

```
Out[462]:
```

```
0    2012-12-31 19:00:00-05:00  
1    2013-01-01 19:00:00-05:00  
2    2013-01-02 19:00:00-05:00  
dtype: datetime64[ns, US/Eastern]
```

Time zone information can also be manipulated using the `astype` method. This method can localize and convert time zone naive timestamps or convert time zone aware timestamps.

```
# localize and convert a naive time zone
```

```
In [463]: s_naive.astype('datetime64[ns, US/Eastern]')
```

```
Out[463]:
```

```
0    2012-12-31 19:00:00-05:00  
1    2013-01-01 19:00:00-05:00  
2    2013-01-02 19:00:00-05:00  
dtype: datetime64[ns, US/Eastern]
```

```
# make an aware tz naive
```

```
In [464]: s_aware.astype('datetime64[ns]')
```

```
Out[464]:
```

```
0    2013-01-01 05:00:00  
1    2013-01-02 05:00:00  
2    2013-01-03 05:00:00  
dtype: datetime64[ns]
```

```
# convert to a new time zone
```

```
In [465]: s_aware.astype('datetime64[ns, CET]')
```

```
Out[465]:
```

```
0    2013-01-01 06:00:00+01:00  
1    2013-01-02 06:00:00+01:00  
2    2013-01-03 06:00:00+01:00  
dtype: datetime64[ns, CET]
```

Note: Using `Series.to_numpy()` on a Series, returns a NumPy array of the data. NumPy does not currently support time zones (even though it is *printing* in the local time zone!), therefore an object array of Timestamps is returned for time zone aware data:

```
In [466]: s_naive.to_numpy()
```

```
Out[466]:
```

```
array(['2013-01-01T00:00:00.000000000', '2013-01-02T00:00:00.000000000',  
      '2013-01-03T00:00:00.000000000'], dtype='datetime64[ns]')
```

(continues on next page)

(continued from previous page)

```
In [467]: s_aware.to_numpy()
Out[467]:
array([Timestamp('2013-01-01 00:00:00-0500', tz='US/Eastern', freq='D'),
       Timestamp('2013-01-02 00:00:00-0500', tz='US/Eastern', freq='D'),
       Timestamp('2013-01-03 00:00:00-0500', tz='US/Eastern', freq='D')],  
dtype=object)
```

By converting to an object array of Timestamps, it preserves the time zone information. For example, when converting back to a Series:

```
In [468]: pd.Series(s_aware.to_numpy())
Out[468]:
0    2013-01-01 00:00:00-05:00
1    2013-01-02 00:00:00-05:00
2    2013-01-03 00:00:00-05:00
dtype: datetime64[ns, US/Eastern]
```

However, if you want an actual NumPy datetime64[ns] array (with the values converted to UTC) instead of an array of objects, you can specify the `dtype` argument:

```
In [469]: s_aware.to_numpy(dtype='datetime64[ns]')
Out[469]:
array(['2013-01-01T05:00:00.000000000', '2013-01-02T05:00:00.000000000',
       '2013-01-03T05:00:00.000000000'], dtype='datetime64[ns]')
```

{{ header }}

3.15 Time deltas

Timedeltas are differences in times, expressed in difference units, e.g. days, hours, minutes, seconds. They can be both positive and negative.

Timedelta is a subclass of `datetime.timedelta`, and behaves in a similar manner, but allows compatibility with `np.timedelta64` types as well as a host of custom representation, parsing, and attributes.

3.15.1 Parsing

You can construct a Timedelta scalar through various arguments:

```
In [1]: import datetime

# strings
In [2]: pd.Timedelta('1 days')
Out[2]: Timedelta('1 days 00:00:00')

In [3]: pd.Timedelta('1 days 00:00:00')
Out[3]: Timedelta('1 days 00:00:00')

In [4]: pd.Timedelta('1 days 2 hours')
Out[4]: Timedelta('1 days 02:00:00')

In [5]: pd.Timedelta('-1 days 2 min 3us')
```

(continues on next page)

(continued from previous page)

```
Out[5]: Timedelta('-2 days +23:57:59.999997')

# like datetime.timedelta
# note: these MUST be specified as keyword arguments
In [6]: pd.Timedelta(days=1, seconds=1)
Out[6]: Timedelta('1 days 00:00:01')

# integers with a unit
In [7]: pd.Timedelta(1, unit='d')
Out[7]: Timedelta('1 days 00:00:00')

# from a datetime.timedelta/np.timedelta64
In [8]: pd.Timedelta(datetime.timedelta(days=1, seconds=1))
Out[8]: Timedelta('1 days 00:00:01')

In [9]: pd.Timedelta(np.timedelta64(1, 'ms'))
Out[9]: Timedelta('0 days 00:00:00.001000')

# negative Timedeltas have this string repr
# to be more consistent with datetime.timedelta conventions
In [10]: pd.Timedelta('-1us')
Out[10]: Timedelta('-1 days +23:59:59.999999')

# a NaT
In [11]: pd.Timedelta('nan')
Out[11]: NaT

In [12]: pd.Timedelta('nat')
Out[12]: NaT

# ISO 8601 Duration strings
In [13]: pd.Timedelta('P0DT0H1M0S')
Out[13]: Timedelta('0 days 00:01:00')

In [14]: pd.Timedelta('P0DT0H0M0.00000123S')
Out[14]: Timedelta('0 days 00:00:00.00000123')
```

New in version 0.23.0: Added constructor for ISO 8601 Duration strings

DateOffsets (Day, Hour, Minute, Second, Milli, Micro, Nano) can also be used in construction.

```
In [15]: pd.Timedelta(pd.offsets.Second(2))
Out[15]: Timedelta('0 days 00:00:02')
```

Further, operations among the scalars yield another scalar Timedelta.

```
In [16]: pd.Timedelta(pd.offsets.Day(2)) + pd.Timedelta(pd.offsets.Second(2)) +\
.....:     pd.Timedelta('00:00:00.000123')
.....:
Out[16]: Timedelta('2 days 00:00:02.000123')
```

to_timedelta

Using the top-level `pd.to_timedelta`, you can convert a scalar, array, list, or Series from a recognized timedelta format / value into a `Timedelta` type. It will construct Series if the input is a Series, a scalar if the input is scalar-like, otherwise it will output a `TimedeltaIndex`.

You can parse a single string to a Timedelta:

```
In [17]: pd.to_timedelta('1 days 06:05:01.00003')
Out[17]: Timedelta('1 days 06:05:01.000030')

In [18]: pd.to_timedelta('15.5us')
Out[18]: Timedelta('0 days 00:00:00.000015')
```

or a list/array of strings:

```
In [19]: pd.to_timedelta(['1 days 06:05:01.00003', '15.5us', 'nan'])
Out[19]: TimedeltaIndex(['1 days 06:05:01.000030', '0 days 00:00:00.000015', NaT],  
                         dtype='timedelta64[ns]', freq=None)
```

The `unit` keyword argument specifies the unit of the Timedelta:

```
In [20]: pd.to_timedelta(np.arange(5), unit='s')
Out[20]: TimedeltaIndex(['00:00:00', '00:00:01', '00:00:02', '00:00:03', '00:00:04'],  
                         dtype='timedelta64[ns]', freq=None)

In [21]: pd.to_timedelta(np.arange(5), unit='d')
Out[21]: TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'], dtype=  
                         'timedelta64[ns]', freq=None)
```

Timedelta limitations

Pandas represents Timedeltas in nanosecond resolution using 64 bit integers. As such, the 64 bit integer limits determine the Timedelta limits.

```
In [22]: pd.Timedelta.min
Out[22]: Timedelta('-106752 days +00:12:43.145224')

In [23]: pd.Timedelta.max
Out[23]: Timedelta('106751 days 23:47:16.854775')
```

3.15.2 Operations

You can operate on Series/DataFrames and construct `timedelta64[ns]` Series through subtraction operations on `datetime64[ns]` Series, or Timestamps.

```
In [24]: s = pd.Series(pd.date_range('2012-1-1', periods=3, freq='D'))
In [25]: td = pd.Series([pd.Timedelta(days=i) for i in range(3)])
In [26]: df = pd.DataFrame({'A': s, 'B': td})
In [27]: df
Out[27]:
```

(continues on next page)

(continued from previous page)

```
A      B  
0 2012-01-01 0 days  
1 2012-01-02 1 days  
2 2012-01-03 2 days
```

```
In [28]: df['C'] = df['A'] + df['B']
```

```
In [29]: df
```

```
Out[29]:
```

```
A      B          C  
0 2012-01-01 0 days 2012-01-01  
1 2012-01-02 1 days 2012-01-03  
2 2012-01-03 2 days 2012-01-05
```

```
In [30]: df.dtypes
```

```
Out[30]:
```

```
A    datetime64[ns]  
B    timedelta64[ns]  
C    datetime64[ns]  
dtype: object
```

```
In [31]: s = s.max()
```

```
Out[31]:
```

```
0 -2 days  
1 -1 days  
2 0 days  
dtype: timedelta64[ns]
```

```
In [32]: s = datetime.datetime(2011, 1, 1, 3, 5)
```

```
Out[32]:
```

```
0 364 days 20:55:00  
1 365 days 20:55:00  
2 366 days 20:55:00  
dtype: timedelta64[ns]
```

```
In [33]: s + datetime.timedelta(minutes=5)
```

```
Out[33]:
```

```
0 2012-01-01 00:05:00  
1 2012-01-02 00:05:00  
2 2012-01-03 00:05:00  
dtype: datetime64[ns]
```

```
In [34]: s + pd.offsets.Minute(5)
```

```
Out[34]:
```

```
0 2012-01-01 00:05:00  
1 2012-01-02 00:05:00  
2 2012-01-03 00:05:00  
dtype: datetime64[ns]
```

```
In [35]: s + pd.offsets.Minute(5) + pd.offsets.Milli(5)
```

```
Out[35]:
```

```
0 2012-01-01 00:05:00.005  
1 2012-01-02 00:05:00.005  
2 2012-01-03 00:05:00.005  
dtype: datetime64[ns]
```

Operations with scalars from a `timedelta64[ns]` series:

```
In [36]: y = s - s[0]
```

```
In [37]: y
```

```
Out[37]:
```

0	0 days
1	1 days
2	2 days

```
dtype: timedelta64[ns]
```

Series of timedeltas with NaT values are supported:

```
In [38]: y = s - s.shift()
```

```
In [39]: y
```

```
Out[39]:
```

0	NaT
1	1 days
2	1 days

```
dtype: timedelta64[ns]
```

Elements can be set to NaT using np.nan analogously to datetimes:

```
In [40]: y[1] = np.nan
```

```
In [41]: y
```

```
Out[41]:
```

0	NaT
1	NaT
2	1 days

```
dtype: timedelta64[ns]
```

Operands can also appear in a reversed order (a singular object operated with a Series):

```
In [42]: s.max() - s
```

```
Out[42]:
```

0	2 days
1	1 days
2	0 days

```
dtype: timedelta64[ns]
```

```
In [43]: datetime.datetime(2011, 1, 1, 3, 5) - s
```

```
Out[43]:
```

0	-365 days +03:05:00
1	-366 days +03:05:00
2	-367 days +03:05:00

```
dtype: timedelta64[ns]
```

```
In [44]: datetime.timedelta(minutes=5) + s
```

```
Out[44]:
```

0	2012-01-01 00:05:00
1	2012-01-02 00:05:00
2	2012-01-03 00:05:00

```
dtype: datetime64[ns]
```

min, max and the corresponding idxmin, idxmax operations are supported on frames:

```
In [45]: A = s - pd.Timestamp('20120101') - pd.Timedelta('00:05:05')

In [46]: B = s - pd.Series(pd.date_range('2012-1-2', periods=3, freq='D'))

In [47]: df = pd.DataFrame({'A': A, 'B': B})

In [48]: df
Out[48]:
          A            B
0 -1 days +23:54:55 -1 days
1  0 days 23:54:55 -1 days
2  1 days 23:54:55 -1 days

In [49]: df.min()
Out[49]:
A -1 days +23:54:55
B -1 days +00:00:00
dtype: timedelta64[ns]

In [50]: df.min(axis=1)
Out[50]:
0 -1 days
1 -1 days
2 -1 days
dtype: timedelta64[ns]

In [51]: df.idxmin()
Out[51]:
A 0
B 0
dtype: int64

In [52]: df.idxmax()
Out[52]:
A 2
B 0
dtype: int64
```

min, max, idxmin, idxmax operations are supported on Series as well. A scalar result will be a Timedelta.

```
In [53]: df.min().max()
Out[53]: Timedelta('-1 days +23:54:55')

In [54]: df.min(axis=1).min()
Out[54]: Timedelta('-1 days +00:00:00')

In [55]: df.min().idxmax()
Out[55]: 'A'

In [56]: df.min(axis=1).idxmin()
Out[56]: 0
```

You can fillna on timedeltas, passing a timedelta to get a particular value.

```
In [57]: y.fillna(pd.Timedelta(0))
Out[57]:
0 0 days
```

(continues on next page)

(continued from previous page)

```

1    0 days
2    1 days
dtype: timedelta64[ns]

In [58]: y.fillna(pd.Timedelta(10, unit='s'))
Out[58]:
0    0 days 00:00:10
1    0 days 00:00:10
2    1 days 00:00:00
dtype: timedelta64[ns]

In [59]: y.fillna(pd.Timedelta('-1 days, 00:00:05'))
Out[59]:
0   -1 days +00:00:05
1   -1 days +00:00:05
2    1 days 00:00:00
dtype: timedelta64[ns]

```

You can also negate, multiply and use abs on Timedeltas:

```

In [60]: td1 = pd.Timedelta('-1 days 2 hours 3 seconds')

In [61]: td1
Out[61]: Timedelta('-2 days +21:59:57')

In [62]: -1 * td1
Out[62]: Timedelta('1 days 02:00:03')

In [63]: - td1
Out[63]: Timedelta('1 days 02:00:03')

In [64]: abs(td1)
Out[64]: Timedelta('1 days 02:00:03')

```

3.15.3 Reductions

Numeric reduction operation for `timedelta64[ns]` will return `Timedelta` objects. As usual `NaT` are skipped during evaluation.

```

In [65]: y2 = pd.Series(pd.to_timedelta(['-1 days +00:00:05', 'nat',
.....:                               '-1 days +00:00:05', '1 days']))
.....:

In [66]: y2
Out[66]:
0   -1 days +00:00:05
1                   NaT
2   -1 days +00:00:05
3    1 days 00:00:00
dtype: timedelta64[ns]

In [67]: y2.mean()
Out[67]: Timedelta('-1 days +16:00:03.333333')

In [68]: y2.median()

```

(continues on next page)

(continued from previous page)

```
Out[68]: Timedelta('-1 days +00:00:05')

In [69]: y2.quantile(.1)
Out[69]: Timedelta('-1 days +00:00:05')

In [70]: y2.sum()
Out[70]: Timedelta('-1 days +00:00:10')
```

3.15.4 Frequency conversion

Timedelta Series, TimedeltaIndex, and Timedelta scalars can be converted to other ‘frequencies’ by dividing by another timedelta, or by astyping to a specific timedelta type. These operations yield Series and propagate NaT -> nan. Note that division by the NumPy scalar is true division, while astyping is equivalent of floor division.

```
In [71]: december = pd.Series(pd.date_range('20121201', periods=4))

In [72]: january = pd.Series(pd.date_range('20130101', periods=4))

In [73]: td = january - december

In [74]: td[2] += datetime.timedelta(minutes=5, seconds=3)

In [75]: td[3] = np.nan

In [76]: td
Out[76]:
0    31 days 00:00:00
1    31 days 00:00:00
2    31 days 00:05:03
3                  NaT
dtype: timedelta64[ns]

# to days
In [77]: td / np.timedelta64(1, 'D')
Out[77]:
0    31.000000
1    31.000000
2    31.003507
3          NaN
dtype: float64

In [78]: td.astype('timedelta64[D]')
Out[78]:
0    31.0
1    31.0
2    31.0
3      NaN
dtype: float64

# to seconds
In [79]: td / np.timedelta64(1, 's')
Out[79]:
0    2678400.0
1    2678400.0
2    2678703.0
```

(continues on next page)

(continued from previous page)

```

3          NaN
dtype: float64

In [80]: td.astype('timedelta64[s]')
Out[80]:
0    2678400.0
1    2678400.0
2    2678703.0
3          NaN
dtype: float64

# to months (these are constant months)
In [81]: td / np.timedelta64(1, 'M')
Out[81]:
0    1.018501
1    1.018501
2    1.018617
3          NaN
dtype: float64

```

Dividing or multiplying a timedelta64[ns] Series by an integer or integer Series yields another timedelta64[ns] dtypes Series.

```

In [82]: td * -1
Out[82]:
0   -31 days +00:00:00
1   -31 days +00:00:00
2   -32 days +23:54:57
3          NaT
dtype: timedelta64[ns]

In [83]: td * pd.Series([1, 2, 3, 4])
Out[83]:
0    31 days 00:00:00
1    62 days 00:00:00
2    93 days 00:15:09
3          NaT
dtype: timedelta64[ns]

```

Rounded division (floor-division) of a timedelta64[ns] Series by a scalar Timedelta gives a series of integers.

```

In [84]: td // pd.Timedelta(days=3, hours=4)
Out[84]:
0    9.0
1    9.0
2    9.0
3    NaN
dtype: float64

In [85]: pd.Timedelta(days=3, hours=4) // td
Out[85]:
0    0.0
1    0.0
2    0.0
3    NaN
dtype: float64

```

The mod (%) and divmod operations are defined for Timedelta when operating with another timedelta-like or with a numeric argument.

```
In [86]: pd.Timedelta(hours=37) % datetime.timedelta(hours=2)
Out[86]: Timedelta('0 days 01:00:00')

# divmod against a timedelta-like returns a pair (int, Timedelta)
In [87]: divmod(datetime.timedelta(hours=2), pd.Timedelta(minutes=11))
Out[87]: (10, Timedelta('0 days 00:10:00'))

# divmod against a numeric returns a pair (Timedelta, Timedelta)
In [88]: divmod(pd.Timedelta(hours=25), 8640000000000000)
Out[88]: (Timedelta('0 days 00:00:00.000000'), Timedelta('0 days 01:00:00'))
```

3.15.5 Attributes

You can access various components of the Timedelta or TimedeltaIndex directly using the attributes `days`, `seconds`, `microseconds`, `nanoseconds`. These are identical to the values returned by `datetime.timedelta`, in that, for example, the `.seconds` attribute represents the number of seconds ≥ 0 and < 1 day. These are signed according to whether the Timedelta is signed.

These operations can also be directly accessed via the `.dt` property of the Series as well.

Note: Note that the attributes are NOT the displayed values of the Timedelta. Use `.components` to retrieve the displayed values.

For a Series:

```
In [89]: td.dt.days
Out[89]:
0    31.0
1    31.0
2    31.0
3    NaN
dtype: float64

In [90]: td.dt.seconds
Out[90]:
0      0.0
1      0.0
2    303.0
3    NaN
dtype: float64
```

You can access the value of the fields for a scalar Timedelta directly.

```
In [91]: tds = pd.Timedelta('31 days 5 min 3 sec')

In [92]: tds.days
Out[92]: 31

In [93]: tds.seconds
Out[93]: 303
```

(continues on next page)

(continued from previous page)

```
In [94]: (-tds).seconds
Out[94]: 86097
```

You can use the `.components` property to access a reduced form of the `timedelta`. This returns a `DataFrame` indexed similarly to the `Series`. These are the *displayed* values of the `Timedelta`.

```
In [95]: td.dt.components
Out[95]:
   days  hours  minutes  seconds  milliseconds  microseconds  nanoseconds
0    31.0     0.0       0.0      0.0            0.0           0.0          0.0
1    31.0     0.0       0.0      0.0            0.0           0.0          0.0
2    31.0     0.0       5.0      3.0            0.0           0.0          0.0
3     NaN     NaN       NaN      NaN            NaN           NaN          NaN

In [96]: td.dt.components.seconds
Out[96]:
0    0.0
1    0.0
2    3.0
3    NaN
Name: seconds, dtype: float64
```

You can convert a `Timedelta` to an ISO 8601 Duration string with the `.isoformat` method

```
In [97]: pd.Timedelta(days=6, minutes=50, seconds=3,
....:                   milliseconds=10, microseconds=10,
....:                   nanoseconds=12).isoformat()
....:
Out[97]: 'P6DT0H50M3.010010012S'
```

3.15.6 TimedeltaIndex

To generate an index with time delta, you can use either the `TimedeltaIndex` or the `timedelta_range()` constructor.

Using `TimedeltaIndex` you can pass string-like, `Timedelta`, `timedelta`, or `np.timedelta64` objects. Passing `np.nan/pd.NaT/nat` will represent missing values.

```
In [98]: pd.TimedeltaIndex(['1 days', '1 days, 00:00:05', np.timedelta64(2, 'D'),
....:                         datetime.timedelta(days=2, seconds=2)])
....:
Out[98]:
TimedeltaIndex(['1 days 00:00:00', '1 days 00:00:05', '2 days 00:00:00',
                '2 days 00:00:02'],
               dtype='timedelta64[ns]', freq=None)
```

The string ‘infer’ can be passed in order to set the frequency of the index as the inferred frequency upon creation:

```
In [99]: pd.TimedeltaIndex(['0 days', '10 days', '20 days'], freq='infer')
Out[99]: TimedeltaIndex(['0 days', '10 days', '20 days'], dtype='timedelta64[ns]',  
                     freq='10D')
```

Generating ranges of time deltas

Similar to `date_range()`, you can construct regular ranges of a `TimedeltaIndex` using `timedelta_range()`. The default frequency for `timedelta_range` is calendar day:

```
In [100]: pd.timedelta_range(start='1 days', periods=5)
Out[100]: TimedeltaIndex(['1 days', '2 days', '3 days', '4 days', '5 days'], dtype='timedelta64[ns]', freq='D')
```

Various combinations of `start`, `end`, and `periods` can be used with `timedelta_range`:

```
In [101]: pd.timedelta_range(start='1 days', end='5 days')
Out[101]: TimedeltaIndex(['1 days', '2 days', '3 days', '4 days', '5 days'], dtype='timedelta64[ns]', freq='D')

In [102]: pd.timedelta_range(end='10 days', periods=4)
Out[102]: TimedeltaIndex(['7 days', '8 days', '9 days', '10 days'], dtype='timedelta64[ns]', freq='D')
```

The `freq` parameter can pass a variety of *frequency aliases*:

```
In [103]: pd.timedelta_range(start='1 days', end='2 days', freq='30T')
Out[103]:
TimedeltaIndex(['1 days 00:00:00', '1 days 00:30:00', '1 days 01:00:00',
               '1 days 01:30:00', '1 days 02:00:00', '1 days 02:30:00',
               '1 days 03:00:00', '1 days 03:30:00', '1 days 04:00:00',
               '1 days 04:30:00', '1 days 05:00:00', '1 days 05:30:00',
               '1 days 06:00:00', '1 days 06:30:00', '1 days 07:00:00',
               '1 days 07:30:00', '1 days 08:00:00', '1 days 08:30:00',
               '1 days 09:00:00', '1 days 09:30:00', '1 days 10:00:00',
               '1 days 10:30:00', '1 days 11:00:00', '1 days 11:30:00',
               '1 days 12:00:00', '1 days 12:30:00', '1 days 13:00:00',
               '1 days 13:30:00', '1 days 14:00:00', '1 days 14:30:00',
               '1 days 15:00:00', '1 days 15:30:00', '1 days 16:00:00',
               '1 days 16:30:00', '1 days 17:00:00', '1 days 17:30:00',
               '1 days 18:00:00', '1 days 18:30:00', '1 days 19:00:00',
               '1 days 19:30:00', '1 days 20:00:00', '1 days 20:30:00',
               '1 days 21:00:00', '1 days 21:30:00', '1 days 22:00:00',
               '1 days 22:30:00', '1 days 23:00:00', '1 days 23:30:00',
               '2 days 00:00:00'],
              dtype='timedelta64[ns]', freq='30T')

In [104]: pd.timedelta_range(start='1 days', periods=5, freq='2D5H')
Out[104]:
TimedeltaIndex(['1 days 00:00:00', '3 days 05:00:00', '5 days 10:00:00',
               '7 days 15:00:00', '9 days 20:00:00'],
              dtype='timedelta64[ns]', freq='53H')
```

New in version 0.23.0.

Specifying `start`, `end`, and `periods` will generate a range of evenly spaced `timedeltas` from `start` to `end` inclusively, with `periods` number of elements in the resulting `TimedeltaIndex`:

```
In [105]: pd.timedelta_range('0 days', '4 days', periods=5)
Out[105]: TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'], dtype='timedelta64[ns]', freq=None)

In [106]: pd.timedelta_range('0 days', '4 days', periods=10)
```

(continues on next page)

(continued from previous page)

Out[106]:

```
TimedeltaIndex(['0 days 00:00:00', '0 days 10:40:00', '0 days 21:20:00',
                 '1 days 08:00:00', '1 days 18:40:00', '2 days 05:20:00',
                 '2 days 16:00:00', '3 days 02:40:00', '3 days 13:20:00',
                 '4 days 00:00:00'],
                dtype='timedelta64[ns]', freq=None)
```

Using the TimedeltaIndex

Similarly to other of the datetime-like indices, DatetimeIndex and PeriodIndex, you can use TimedeltaIndex as the index of pandas objects.

```
In [107]: s = pd.Series(np.arange(100),
.....:                     index=pd.timedelta_range('1 days', periods=100, freq='h'))
.....:

In [108]: s
Out[108]:
1 days 00:00:00    0
1 days 01:00:00    1
1 days 02:00:00    2
1 days 03:00:00    3
1 days 04:00:00    4
...
4 days 23:00:00    95
5 days 00:00:00    96
5 days 01:00:00    97
5 days 02:00:00    98
5 days 03:00:00    99
Freq: H, Length: 100, dtype: int64
```

Selections work similarly, with coercion on string-likes and slices:

```
In [109]: s['1 day':'2 day']
```

```
Out[109]:
```

```
1 days 00:00:00    0
1 days 01:00:00    1
1 days 02:00:00    2
1 days 03:00:00    3
1 days 04:00:00    4
1 days 05:00:00    5
1 days 06:00:00    6
1 days 07:00:00    7
1 days 08:00:00    8
1 days 09:00:00    9
1 days 10:00:00   10
1 days 11:00:00   11
1 days 12:00:00   12
1 days 13:00:00   13
1 days 14:00:00   14
1 days 15:00:00   15
1 days 16:00:00   16
1 days 17:00:00   17
1 days 18:00:00   18
1 days 19:00:00   19
```

(continues on next page)

(continued from previous page)

```
1 days 20:00:00    20
1 days 21:00:00    21
1 days 22:00:00    22
1 days 23:00:00    23
2 days 00:00:00    24
2 days 01:00:00    25
2 days 02:00:00    26
2 days 03:00:00    27
2 days 04:00:00    28
2 days 05:00:00    29
2 days 06:00:00    30
2 days 07:00:00    31
2 days 08:00:00    32
2 days 09:00:00    33
2 days 10:00:00    34
2 days 11:00:00    35
2 days 12:00:00    36
2 days 13:00:00    37
2 days 14:00:00    38
2 days 15:00:00    39
2 days 16:00:00    40
2 days 17:00:00    41
2 days 18:00:00    42
2 days 19:00:00    43
2 days 20:00:00    44
2 days 21:00:00    45
2 days 22:00:00    46
2 days 23:00:00    47
Freq: H, dtype: int64
```

```
In [110]: s['1 day 01:00:00']
Out[110]: 1
```

```
In [111]: s[pd.Timedelta('1 day 1h')]
Out[111]: 1
```

Furthermore you can use partial string selection and the range will be inferred:

```
In [112]: s['1 day':'1 day 5 hours']
Out[112]:
1 days 00:00:00    0
1 days 01:00:00    1
1 days 02:00:00    2
1 days 03:00:00    3
1 days 04:00:00    4
1 days 05:00:00    5
Freq: H, dtype: int64
```

Operations

Finally, the combination of TimedeltaIndex with DatetimeIndex allow certain combination operations that are NaT preserving:

```
In [113]: tdi = pd.TimedeltaIndex(['1 days', pd.NaT, '2 days'])

In [114]: tdi.to_list()
Out[114]: [Timedelta('1 days 00:00:00'), NaT, Timedelta('2 days 00:00:00')]

In [115]: dti = pd.date_range('20130101', periods=3)

In [116]: dti.to_list()
Out[116]:
[Timestamp('2013-01-01 00:00:00', freq='D'),
 Timestamp('2013-01-02 00:00:00', freq='D'),
 Timestamp('2013-01-03 00:00:00', freq='D')]

In [117]: (dti + tdi).to_list()
Out[117]: [Timestamp('2013-01-02 00:00:00'), NaT, Timestamp('2013-01-05 00:00:00')]

In [118]: (dti - tdi).to_list()
Out[118]: [Timestamp('2012-12-31 00:00:00'), NaT, Timestamp('2013-01-01 00:00:00')]
```

Conversions

Similarly to frequency conversion on a Series above, you can convert these indices to yield another Index.

```
In [119]: tdi / np.timedelta64(1, 's')
Out[119]: Float64Index([86400.0, nan, 172800.0], dtype='float64')

In [120]: tdi.astype('timedelta64[s]')
Out[120]: Float64Index([86400.0, nan, 172800.0], dtype='float64')
```

Scalars type ops work as well. These can potentially return a *different* type of index.

```
# adding or timedelta and date -> datelike
In [121]: tdi + pd.Timestamp('20130101')
Out[121]: DatetimeIndex(['2013-01-02', 'NaT', '2013-01-03'], dtype='datetime64[ns]', freq=None)

# subtraction of a date and a timedelta -> datelike
# note that trying to subtract a date from a Timedelta will raise an exception
In [122]: (pd.Timestamp('20130101') - tdi).to_list()
Out[122]: [Timestamp('2012-12-31 00:00:00'), NaT, Timestamp('2012-12-30 00:00:00')]

# timedelta + timedelta -> timedelta
In [123]: tdi + pd.Timedelta('10 days')
Out[123]: TimedeltaIndex(['11 days', NaT, '12 days'], dtype='timedelta64[ns]', freq=None)

# division can result in a Timedelta if the divisor is an integer
In [124]: tdi / 2
Out[124]: TimedeltaIndex(['0 days 12:00:00', NaT, '1 days 00:00:00'], dtype='timedelta64[ns]', freq=None)
```

(continues on next page)

(continued from previous page)

```
# or a Float64Index if the divisor is a Timedelta
In [125]: tdi / tdi[0]
Out[125]: Float64Index([1.0, nan, 2.0], dtype='float64')
```

3.15.7 Resampling

Similar to *timeseries resampling*, we can resample with a TimedeltaIndex.

```
In [126]: s.resample('D').mean()
Out[126]:
1 days    11.5
2 days    35.5
3 days    59.5
4 days   83.5
5 days   97.5
Freq: D, dtype: float64
```

3.16 Styling

This document is written as a Jupyter Notebook, and can be viewed or downloaded [here](#).

You can apply **conditional formatting**, the visual styling of a DataFrame depending on the data within, by using the `DataFrame.style` property. This is a property that returns a `Styler` object, which has useful methods for formatting and displaying DataFrames.

The styling is accomplished using CSS. You write “style functions” that take scalars, DataFrames or Series, and return *like-indexed* DataFrames or Series with CSS “attribute: value” pairs for the values. These functions can be incrementally passed to the `Styler` which collects the styles before rendering.

3.16.1 Building styles

Pass your style functions into one of the following methods:

- `Styler.applymap`: elementwise
- `Styler.apply`: column-/row-/table-wise

Both of those methods take a function (and some other keyword arguments) and applies your function to the DataFrame in a certain way. `Styler.applymap` works through the DataFrame elementwise. `Styler.apply` passes each column or row into your DataFrame one-at-a-time or the entire table at once, depending on the `axis` keyword argument. For columnwise use `axis=0`, rowwise use `axis=1`, and for the entire table at once use `axis=None`.

For `Styler.applymap` your function should take a scalar and return a single string with the CSS attribute-value pair.

For `Styler.apply` your function should take a Series or DataFrame (depending on the `axis` parameter), and return a Series or DataFrame with an identical shape where each value is a string with a CSS attribute-value pair.

Let's see some examples.

```
[2]: import pandas as pd
import numpy as np
```

(continues on next page)

(continued from previous page)

```
np.random.seed(24)
df = pd.DataFrame({'A': np.linspace(1, 10, 10)})
df = pd.concat([df, pd.DataFrame(np.random.randn(10, 4), columns=list('BCDE'))],
               axis=1)
df.iloc[3, 3] = np.nan
df.iloc[0, 2] = np.nan
```

Here's a boring example of rendering a DataFrame, without any (visible) styles:

```
[3]: df.style
[3]: <pandas.io.formats.style.Styler at 0x7f435bc394d0>
```

Note: The DataFrame.style attribute is a property that returns a Styler object. Styler has a _repr_html_ method defined on it so they are rendered automatically. If you want the actual HTML back for further processing or for writing to file call the .render() method which returns a string.

The above output looks very similar to the standard DataFrame HTML representation. But we've done some work behind the scenes to attach CSS classes to each cell. We can view these by calling the .render method.

```
[4]: df.style.highlight_null().render().split('\n')[:10]
[4]: ['<style type="text/css">',
      '  #T_436566e4_6236_11ea_af95_0242ac110002row0_col2 {',
      '    background-color: red;',
      '  } #T_436566e4_6236_11ea_af95_0242ac110002row3_col3 {',
      '    background-color: red;',
      '}</style><table id="T_436566e4_6236_11ea_af95_0242ac110002" ><thead> <tr>
      <th class="blank level0" ></th> <th class="col_heading level0 col0" >
      A</th> <th class="col_heading level0 col1" >B</th> <th class="col_
      heading level0 col2" >C</th> <th class="col_heading level0 col3" >D</th>
      <th class="col_heading level0 col4" >E</th> </tr></thead><tbody>',
      '  <tr>',
      '    <th id="T_436566e4_6236_11ea_af95_0242ac110002level0_row0"_
      class="row_heading level0 row0" >0</th>',
      '    <td id="T_436566e4_6236_11ea_af95_0242ac110002row0_col0"_
      class="data row0 col0" >1.000000</td>',
      '    <td id="T_436566e4_6236_11ea_af95_0242ac110002row0_col1"_
      class="data row0 col1" >1.329212</td>']
```

The row0_col2 is the identifier for that particular cell. We've also prepended each row/column identifier with a UUID unique to each DataFrame so that the style from one doesn't collide with the styling from another within the same notebook or page (you can set the `uuid` if you'd like to tie together the styling of two DataFrames).

When writing style functions, you take care of producing the CSS attribute / value pairs you want. Pandas matches those up with the CSS classes that identify each cell.

Let's write a simple style function that will color negative numbers red and positive numbers black.

```
[5]: def color_negative_red(val):
    """
    Takes a scalar and returns a string with
    the css property ``color: red`` for negative
    strings, black otherwise.
    """
    color = 'red' if val < 0 else 'black'
    return 'color: %s' % color
```

In this case, the cell's style depends only on it's own value. That means we should use the `Styler.applymap` method which works elementwise.

```
[6]: s = df.style.applymap(color_negative_red)
s
[6]: <pandas.io.formats.style.Styler at 0x7f4359649ad0>
```

Notice the similarity with the standard `df.applymap`, which operates on DataFrames elementwise. We want you to be able to reuse your existing knowledge of how to interact with DataFrames.

Notice also that our function returned a string containing the CSS attribute and value, separated by a colon just like in a `<style>` tag. This will be a common theme.

Finally, the input shapes matched. `Styler.applymap` calls the function on each scalar input, and the function returns a scalar output.

Now suppose you wanted to highlight the maximum value in each column. We can't use `.applymap` anymore since that operated elementwise. Instead, we'll turn to `.apply` which operates columnwise (or rowwise using the `axis` keyword). Later on we'll see that something like `highlight_max` is already defined on `Styler` so you wouldn't need to write this yourself.

```
[7]: def highlight_max(s):
    """
    highlight the maximum in a Series yellow.
    """
    is_max = s == s.max()
    return ['background-color: yellow' if v else '' for v in is_max]
```

```
[8]: df.style.apply(highlight_max)
[8]: <pandas.io.formats.style.Styler at 0x7f435963ead0>
```

In this case the input is a `Series`, one column at a time. Notice that the output shape of `highlight_max` matches the input shape, an array with `len(s)` items.

We encourage you to use method chains to build up a style piecewise, before finally rendering at the end of the chain.

```
[9]: df.style.\
    applymap(color_negative_red).\ \
    apply(highlight_max)
[9]: <pandas.io.formats.style.Styler at 0x7f435963e150>
```

Above we used `Styler.apply` to pass in each column one at a time.

Debugging Tip: If you're having trouble writing your style function, try just passing it into `DataFrame.apply`. Internally, `Styler.apply` uses `DataFrame.apply` so the result should be the same.

What if you wanted to highlight just the maximum value in the entire table? Use `.apply(function, axis=None)` to indicate that your function wants the entire table, not one column or row at a time. Let's try that next.

We'll rewrite our `highlight_max` to handle either `Series` (from `.apply(axis=0 or 1)`) or `DataFrames` (from `.apply(axis=None)`). We'll also allow the color to be adjustable, to demonstrate that `.apply`, and `.applymap` pass along keyword arguments.

```
[10]: def highlight_max(data, color='yellow'):
    """
    highlight the maximum in a Series or DataFrame
```

(continues on next page)

(continued from previous page)

```

    """
    attr = 'background-color: {}'.format(color)
    if data.ndim == 1: # Series from .apply(axis=0) or axis=1
        is_max = data == data.max()
        return [attr if v else '' for v in is_max]
    else: # from .apply(axis=None)
        is_max = data == data.max().max()
        return pd.DataFrame(np.where(is_max, attr, ''),
                            index=data.index, columns=data.columns)

```

When using Styler.apply(func, axis=None), the function must return a DataFrame with the same index and column labels.

```
[11]: df.style.apply(highlight_max, color='darkorange', axis=None)
[11]: <pandas.io.formats.style.Styler at 0x7f4359609910>
```

Building Styles Summary

Style functions should return strings with one or more CSS attribute: value delimited by semicolons. Use

- Styler.applymap(func) for elementwise styles
- Styler.apply(func, axis=0) for columnwise styles
- Styler.apply(func, axis=1) for rowwise styles
- Styler.apply(func, axis=None) for tablewise styles

And crucially the input and output shapes of func must match. If x is the input then func(x).shape == x.shape.

3.16.2 Finer control: slicing

Both Styler.apply, and Styler.applymap accept a subset keyword. This allows you to apply styles to specific rows or columns, without having to code that logic into your style function.

The value passed to subset behaves similar to slicing a DataFrame.

- A scalar is treated as a column label
- A list (or series or numpy array)
- A tuple is treated as (row_indexer, column_indexer)

Consider using pd.IndexSlice to construct the tuple for the last one.

```
[12]: df.style.apply(highlight_max, subset=['B', 'C', 'D'])
[12]: <pandas.io.formats.style.Styler at 0x7f43595b4a10>
```

For row and column slicing, any valid indexer to .loc will work.

```
[13]: df.style.applymap(color_negative_red,
                      subset=pd.IndexSlice[2:5, ['B', 'D']])
[13]: <pandas.io.formats.style.Styler at 0x7f43595c30d0>
```

Only label-based slicing is supported right now, not positional.

If your style function uses a `subset` or `axis` keyword argument, consider wrapping your function in a `functools.partial`, partialing out that keyword.

```
my_func2 = functools.partial(my_func, subset=42)
```

3.16.3 Finer Control: Display Values

We distinguish the *display* value from the *actual* value in Styler. To control the display value, the text is printed in each cell, use `Styler.format`. Cells can be formatted according to a `format spec string` or a callable that takes a single value and returns a string.

```
[14]: df.style.format(":.2%")  
[14]: <pandas.io.formats.style.Styler at 0x7f4359609c90>
```

Use a dictionary to format specific columns.

```
[15]: df.style.format({'B': '{:0<4.0f}', 'D': '{:+.2f}'})  
[15]: <pandas.io.formats.style.Styler at 0x7f43595c31d0>
```

Or pass in a callable (or dictionary of callables) for more flexible handling.

```
[16]: df.style.format({"B": lambda x: "\u00b1{:.2f}".format(abs(x))})  
[16]: <pandas.io.formats.style.Styler at 0x7f43595c3c10>
```

You can format the text displayed for missing values by `na_rep`.

```
[17]: df.style.format(":.2%", na_rep="-")  
[17]: <pandas.io.formats.style.Styler at 0x7f4359642d10>
```

These formatting techniques can be used in combination with styling.

```
[18]: df.style.highlight_max().format(None, na_rep="-")  
[18]: <pandas.io.formats.style.Styler at 0x7f43596097d0>
```

3.16.4 Builtin styles

Finally, we expect certain styling functions to be common enough that we've included a few "built-in" to the Styler, so you don't have to write them yourself.

```
[19]: df.style.highlight_null(null_color='red')  
[19]: <pandas.io.formats.style.Styler at 0x7f4358d14fd0>
```

You can create "heatmaps" with the `background_gradient` method. These require matplotlib, and we'll use Seaborn to get a nice colormap.

```
[20]: import seaborn as sns  
  
cm = sns.light_palette("green", as_cmap=True)
```

(continues on next page)

(continued from previous page)

```
s = df.style.background_gradient(cmap=cm)
s
/opt/conda/envs/pandas/lib/python3.7/site-packages/matplotlib/colors.py:527:_
  RuntimeWarning: invalid value encountered in less
    xa[xa < 0] = -1
[20]: <pandas.io.formats.style.Styler at 0x7f43595c3dd0>
```

`Styler.background_gradient` takes the keyword arguments `low` and `high`. Roughly speaking these extend the range of your data by `low` and `high` percent so that when we convert the colors, the colormap's entire range isn't used. This is useful so that you can actually read the text still.

```
[21]: # Uses the full color range
df.loc[:4].style.background_gradient(cmap='viridis')
[21]: <pandas.io.formats.style.Styler at 0x7f4356c50c10>
```

```
[22]: # Compress the color range
(df.loc[:4]
 .style
 .background_gradient(cmap='viridis', low=.5, high=0)
 .highlight_null('red'))
[22]: <pandas.io.formats.style.Styler at 0x7f4356c56450>
```

There's also `.highlight_min` and `.highlight_max`.

```
[23]: df.style.highlight_max(axis=0)
[23]: <pandas.io.formats.style.Styler at 0x7f4356c62290>
```

Use `Styler.set_properties` when the style doesn't actually depend on the values.

```
[24]: df.style.set_properties(**{'background-color': 'black',
                             'color': 'lawngreen',
                             'border-color': 'white'})
[24]: <pandas.io.formats.style.Styler at 0x7f4358d14f10>
```

Bar charts

You can include “bar charts” in your DataFrame.

```
[25]: df.style.bar(subset=['A', 'B'], color='#d65f5f')
[25]: <pandas.io.formats.style.Styler at 0x7f4356c628d0>
```

New in version 0.20.0 is the ability to customize further the bar chart: You can now have the `df.style.bar` be centered on zero or midpoint value (in addition to the already existing way of having the min value at the left side of the cell), and you can pass a list of `[color_negative, color_positive]`.

Here's how you can change the above with the new `align='mid'` option:

```
[26]: df.style.bar(subset=['A', 'B'], align='mid', color=['#d65f5f', '#5fba7d'])
[26]: <pandas.io.formats.style.Styler at 0x7f4356bf1110>
```

The following example aims to give a highlight of the behavior of the new align options:

```
[27]: import pandas as pd
from IPython.display import HTML

# Test series
test1 = pd.Series([-100,-60,-30,-20], name='All Negative')
test2 = pd.Series([10,20,50,100], name='All Positive')
test3 = pd.Series([-10,-5,0,90], name='Both Pos and Neg')

head = """
<table>
    <thead>
        <th>Align</th>
        <th>All Negative</th>
        <th>All Positive</th>
        <th>Both Neg and Pos</th>
    </thead>
    <tbody>

aligns = ['left','zero','mid']
for align in aligns:
    row = "<tr><th>{}</th>".format(align)
    for serie in [test1,test2,test3]:
        s = serie.copy()
        s.name=''
        row += "<td>{}</td>".format(s.to_frame().style.bar(align=align,
                                                               color=['#d65f5f', '#5fba7d
                                                               ],
                                                               width=100).render())
    #testn['width']
    row += '</tr>'
    head += row

head+= """
</tbody>
</table>"""

HTML(head)
```

[27]: <IPython.core.display.HTML object>

3.16.5 Sharing styles

Say you have a lovely style built up for a DataFrame, and now you want to apply the same style to a second DataFrame. Export the style with `df1.style.export`, and import it on the second DataFrame with `df1.style.set`

```
[28]: df2 = -df
style1 = df.style.applymap(color_negative_red)
style1
```

[28]: <pandas.io.formats.style.Styler at 0x7f4356bfe590>

```
[29]: style2 = df2.style
style2.use(style1.export())
style2
```

[29]: <pandas.io.formats.style.Styler at 0x7f4356c05d50>

Notice that you're able to share the styles even though they're data aware. The styles are re-evaluated on the new DataFrame they've been used upon.

3.16.6 Other Options

You've seen a few methods for data-driven styling. Styler also provides a few other options for styles that don't depend on the data.

- precision
- captions
- table-wide styles
- missing values representation
- hiding the index or columns

Each of these can be specified in two ways:

- A keyword argument to `Styler.__init__`
- A call to one of the `.set_` or `.hide_` methods, e.g. `.set_caption` or `.hide_columns`

The best method to use depends on the context. Use the Styler constructor when building many styled DataFrames that should all share the same properties. For interactive use, the `.set_` and `.hide_` methods are more convenient.

Precision

You can control the precision of floats using pandas' regular `display.precision` option.

[30]:

```
with pd.option_context('display.precision', 2):
    html = (df.style
        .applymap(color_negative_red)
        .apply(highlight_max))
html
```

[30]: <pandas.io.formats.style.Styler at 0x7f4356c22810>

Or through a `set_precision` method.

[31]:

```
df.style\
    .applymap(color_negative_red)\ \
    .apply(highlight_max)\ \
    .set_precision(2)
```

[31]: <pandas.io.formats.style.Styler at 0x7f4356bf8ed0>

Setting the precision only affects the printed number; the full-precision values are always passed to your style functions. You can always use `df.round(2).style` if you'd prefer to round from the start.

Captions

Regular table captions can be added in a few ways.

```
[32]: df.style.set_caption('Colormaps, with a caption.') \
    .background_gradient(cmap=cm)
```

```
[32]: <pandas.io.formats.style.Styler at 0x7f4356c1ef10>
```

Table styles

The next option you have are “table styles”. These are styles that apply to the table as a whole, but don’t look at the data. Certain sytlings, including pseudo-selectors like :hover can only be used this way.

```
[33]: from IPython.display import HTML

def hover(hover_color="#ffff99"):
    return dict(selector="tr:hover",
                props=[("background-color", "%s" % hover_color)])

styles = [
    hover(),
    dict(selector="th", props=[("font-size", "150%"),
                               ("text-align", "center")]),
    dict(selector="caption", props=[("caption-side", "bottom")])
]
html = (df.style.set_table_styles(styles)
        .set_caption("Hover to highlight."))
html
```

```
[33]: <pandas.io.formats.style.Styler at 0x7f4356c1de10>
```

table_styles should be a list of dictionaries. Each dictionary should have the selector and props keys. The value for selector should be a valid CSS selector. Recall that all the styles are already attached to an id, unique to each Styler. This selector is in addition to that id. The value for props should be a list of tuples of ('attribute', 'value').

table_styles are extremely flexible, but not as fun to type out by hand. We hope to collect some useful ones either in pandas, or preferable in a new package that *builds on top* the tools here.

Missing values

You can control the default missing values representation for the entire table through set_na_rep method.

```
[34]: (df.style
       .set_na_rep("FAIL")
       .format(None, na_rep="PASS", subset=["D"])
       .highlight_null("yellow"))
```

```
[34]: <pandas.io.formats.style.Styler at 0x7f4356c21850>
```

Hiding the Index or Columns

The index can be hidden from rendering by calling `Styler.hide_index`. Columns can be hidden from rendering by calling `Styler.hide_columns` and passing in the name of a column, or a slice of columns.

```
[35]: df.style.hide_index()  
[35]: <pandas.io.formats.style.Styler at 0x7f4356bf1250>  
  
[36]: df.style.hide_columns(['C', 'D'])  
[36]: <pandas.io.formats.style.Styler at 0x7f4356c21590>
```

CSS classes

Certain CSS classes are attached to cells.

- Index and Column names include `index_name` and `level<k>` where `k` is its level in a MultiIndex
- Index label cells include
 - `row_heading`
 - `row<n>` where `n` is the numeric position of the row
 - `level<k>` where `k` is the level in a MultiIndex
- Column label cells include
 - `col_heading`
 - `col<n>` where `n` is the numeric position of the column
 - `level<k>` where `k` is the level in a MultiIndex
- Blank cells include `blank`
- Data cells include `data`

Limitations

- DataFrame only (use `Series.to_frame().style`)
- The index and columns must be unique
- No large repr, and performance isn't great; this is intended for summary DataFrames
- You can only style the *values*, not the index or columns
- You can only apply styles, you can't insert new HTML entities

Some of these will be addressed in the future.

Terms

- Style function: a function that's passed into Styler.apply or Styler.applymap and returns values like '`css attribute: value`'
- Builtin style functions: style functions that are methods on Styler
- table style: a dictionary with the two keys selector and props. selector is the CSS selector that props will apply to. props is a list of (attribute, value) tuples. A list of table styles passed into Styler.

3.16.7 Fun stuff

Here are a few interesting examples.

Styler interacts pretty well with widgets. If you're viewing this online instead of running the notebook yourself, you're missing out on interactively adjusting the color palette.

```
[37]: from IPython.html import widgets
@widgets.interact
def f(h_neg=(0, 359, 1), h_pos=(0, 359), s=(0., 99.9), l=(0., 99.9)):
    return df.style.background_gradient(
        cmap=sns.palettes.diverging_palette(h_neg=h_neg, h_pos=h_pos, s=s, l=l,
                                             as_cmap=True)
)
<pandas.io.formats.style.Styler at 0x7f4356c1ebd0>
```

```
[38]: def magnify():
    return [dict(selector="th",
                 props=[("font-size", "4pt")]),
            dict(selector="td",
                 props=[('padding', "0em 0em")]),
            dict(selector="th:hover",
                 props=[("font-size", "12pt")]),
            dict(selector="tr:hover td:hover",
                 props=[('max-width', '200px'),
                       ('font-size', '12pt')])
]
```

```
[39]: np.random.seed(25)
cmap = cmap=sns.diverging_palette(5, 250, as_cmap=True)
bigdf = pd.DataFrame(np.random.randn(20, 25)).cumsum()

bigdf.style.background_gradient(cmap, axis=1) \
    .set_properties(**{'max-width': '80px', 'font-size': '1pt'}) \
    .set_caption("Hover to magnify") \
    .set_precision(2) \
    .set_table_styles(magnify())
<pandas.io.formats.style.Styler at 0x7f4356bf8950>
```

3.16.8 Export to Excel

New in version 0.20.0

Experimental: This is a new feature and still under development. We'll be adding features and possibly making breaking changes in future releases. We'd love to hear your feedback.

Some support is available for exporting styled DataFrames to Excel worksheets using the OpenPyXL or XlsxWriter engines. CSS2.2 properties handled include:

- background-color
- border-style, border-width, border-color and their {top, right, bottom, left variants}
- color
- font-family
- font-style
- font-weight
- text-align
- text-decoration
- vertical-align
- white-space: nowrap
- Only CSS2 named colors and hex colors of the form #rgb or #rrggbb are currently supported.
- The following pseudo CSS properties are also available to set excel specific style properties:
 - number-format

```
[40]: df.style.\n    applymap(color_negative_red).\\n    apply(highlight_max).\\n    to_excel('styled.xlsx', engine='openpyxl')
```

A screenshot of the output:

	A	B	C	D	E	F
1		A	B	C	D	E
2	0		1 1.329212		-0.31628	-0.99081
3	1		2 -1.070816	-1.438713	0.564417	0.295722
4	2		3 -1.626404	0.219565	0.678805	1.889273
5	3		4 0.961538	0.104011	-0.481165	0.850229
6	4		5 1.453425	1.057737	0.165562	0.515018
7	5		6 -1.336936	0.562861	1.392855	-0.063328
8	6		7 0.121668	1.207603	-0.00204	1.627796
9	7		8 0.354493	1.037528	-0.385684	0.519818
10	8		9 1.686583	-1.325963	1.428984	-2.089354
11	9	10	-0.12982	0.631523	-0.586538	0.29072

3.16.9 Extensibility

The core of pandas is, and will remain, its “high-performance, easy-to-use data structures”. With that in mind, we hope that `DataFrame.style` accomplishes two goals

- Provide an API that is pleasing to use interactively and is “good enough” for many tasks
- Provide the foundations for dedicated libraries to build on

If you build a great library on top of this, let us know and we’ll [link](#) to it.

Subclassing

If the default template doesn’t quite suit your needs, you can subclass `Styler` and extend or override the template. We’ll show an example of extending the default template to insert a custom header before each table.

```
[41]: from jinja2 import Environment, ChoiceLoader, FileSystemLoader
from IPython.display import HTML
from pandas.io.formats.style import Styler
```

We’ll use the following template:

```
[42]: with open("templates/myhtml.tpl") as f:
    print(f.read())

{% extends "html.tpl" %}
{% block table %}
<h1>{{ table_title|default("My Table") }}</h1>
{{ super() }}
{% endblock table %}
```

Now that we’ve created a template, we need to set up a subclass of `Styler` that knows about it.

```
[43]: class MyStyler(Styler):
    env = Environment(
        loader=ChoiceLoader([
            FileSystemLoader("templates"), # contains ours
            Styler.loader, # the default
        ])
    )
    template = env.get_template("myhtml.tpl")
```

Notice that we include the original loader in our environment’s loader. That’s because we extend the original template, so the Jinja environment needs to be able to find it.

Now we can use that custom styler. It’s `__init__` takes a `DataFrame`.

```
[44]: MyStyler(df)
[44]: <__main__.MyStyler at 0x7f43542b8810>
```

Our custom template accepts a `table_title` keyword. We can provide the value in the `.render` method.

```
[45]: HTML(MyStyler(df).render(table_title="Extending Example"))
[45]: <IPython.core.display.HTML object>
```

For convenience, we provide the `Styler.from_custom_template` method that does the same as the custom subclass.

```
[46]: EasyStyler = Styler.from_custom_template("templates", "myhtml.tpl")
EasyStyler(df)

[46]: <pandas.io.formats.style.Styler.from_custom_template.<locals>.MyStyler at
      ↪0x7f4354246910>
```

Here's the template structure:

```
[47]: with open("templates/template_structure.html") as f:
    structure = f.read()

HTML(structure)

[47]: <IPython.core.display.HTML object>
```

See the template in the [GitHub repo](#) for more details.

`{} header {}`

3.17 Options and settings

3.17.1 Overview

pandas has an options system that lets you customize some aspects of its behaviour, display-related options being those the user is most likely to adjust.

Options have a full “dotted-style”, case-insensitive name (e.g. `display.max_rows`). You can get/set options directly as attributes of the top-level `options` attribute:

```
In [1]: import pandas as pd

In [2]: pd.options.display.max_rows
Out[2]: 60

In [3]: pd.options.display.max_rows = 999

In [4]: pd.options.display.max_rows
Out[4]: 999
```

The API is composed of 5 relevant functions, available directly from the `pandas` namespace:

- `get_option()` / `set_option()` - get/set the value of a single option.
- `reset_option()` - reset one or more options to their default value.
- `describe_option()` - print the descriptions of one or more options.
- `option_context()` - execute a codeblock with a set of options that revert to prior settings after execution.

Note: Developers can check out `pandas/core/config.py` for more information.

All of the functions above accept a regexp pattern (`re.search` style) as an argument, and so passing in a substring will work - as long as it is unambiguous:

```
In [5]: pd.get_option("display.max_rows")
Out[5]: 999

In [6]: pd.set_option("display.max_rows", 101)
```

(continues on next page)

(continued from previous page)

```
In [7]: pd.get_option("display.max_rows")
Out[7]: 101

In [8]: pd.set_option("max_r", 102)

In [9]: pd.get_option("display.max_rows")
Out[9]: 102
```

The following will **not work** because it matches multiple option names, e.g. `display.max_colwidth`, `display.max_rows`, `display.max_columns`:

```
In [10]: try:
....:     pd.get_option("column")
....: except KeyError as e:
....:     print(e)
....:
'Pattern matched multiple keys'
```

Note: Using this form of shorthand may cause your code to break if new options with similar names are added in future versions.

You can get a list of available options and their descriptions with `describe_option`. When called with no argument `describe_option` will print out the descriptions for all available options.

3.17.2 Getting and setting options

As described above, `get_option()` and `set_option()` are available from the pandas namespace. To change an option, call `set_option('option regex', new_value)`.

```
In [11]: pd.get_option('mode.sim_interactive')
Out[11]: False

In [12]: pd.set_option('mode.sim_interactive', True)

In [13]: pd.get_option('mode.sim_interactive')
Out[13]: True
```

Note: The option ‘`mode.sim_interactive`’ is mostly used for debugging purposes.

All options also have a default value, and you can use `reset_option` to do just that:

```
In [14]: pd.get_option("display.max_rows")
Out[14]: 60

In [15]: pd.set_option("display.max_rows", 999)

In [16]: pd.get_option("display.max_rows")
Out[16]: 999

In [17]: pd.reset_option("display.max_rows")

In [18]: pd.get_option("display.max_rows")
Out[18]: 60
```

It’s also possible to reset multiple options at once (using a regex):

```
In [19]: pd.reset_option("^display")
```

option_context context manager has been exposed through the top-level API, allowing you to execute code with given option values. Option values are restored automatically when you exit the `with` block:

```
In [20]: with pd.option_context("display.max_rows", 10, "display.max_columns", 5):
....:     print(pd.get_option("display.max_rows"))
....:     print(pd.get_option("display.max_columns"))
....:
10
5

In [21]: print(pd.get_option("display.max_rows"))
60

In [22]: print(pd.get_option("display.max_columns"))
0
```

3.17.3 Setting startup options in Python/IPython environment

Using startup scripts for the Python/IPython environment to import pandas and set options makes working with pandas more efficient. To do this, create a `.py` or `.ipy` script in the startup directory of the desired profile. An example where the startup folder is in a default ipython profile can be found at:

```
$IPYTHONDIR/profile_default/startup
```

More information can be found in the [ipython documentation](#). An example startup script for pandas is displayed below:

```
import pandas as pd
pd.set_option('display.max_rows', 999)
pd.set_option('precision', 5)
```

3.17.4 Frequently Used Options

The following is a walk-through of the more frequently used display options.

`display.max_rows` and `display.max_columns` sets the maximum number of rows and columns displayed when a frame is pretty-printed. Truncated lines are replaced by an ellipsis.

```
In [23]: df = pd.DataFrame(np.random.randn(7, 2))
```

```
In [24]: pd.set_option('max_rows', 7)
```

```
In [25]: df
```

```
Out[25]:
```

	0	1
0	-0.228248	-2.069612
1	0.610144	0.423497
2	1.117887	-0.274242
3	1.741812	-0.447501
4	-1.255427	0.938164
5	-0.468346	-1.254720
6	0.124824	0.756502

(continues on next page)

(continued from previous page)

```
In [26]: pd.set_option('max_rows', 5)
```

```
In [27]: df
```

```
Out[27]:
```

```
      0          1  
0 -0.228248 -2.069612  
1  0.610144  0.423497  
..   ...     ...  
5 -0.468346 -1.254720  
6  0.124824  0.756502
```

```
[7 rows x 2 columns]
```

```
In [28]: pd.reset_option('max_rows')
```

Once the `display.max_rows` is exceeded, the `display.min_rows` options determines how many rows are shown in the truncated repr.

```
In [29]: pd.set_option('max_rows', 8)
```

```
In [30]: pd.set_option('min_rows', 4)
```

```
# below max_rows -> all rows shown
```

```
In [31]: df = pd.DataFrame(np.random.randn(7, 2))
```

```
In [32]: df
```

```
Out[32]:
```

```
      0          1  
0  0.241440  0.497426  
1  4.108693  0.821121  
2  1.531760 -1.985846  
3  0.365054  0.774082  
4 -0.364479 -0.875979  
5  0.396520 -0.314617  
6 -0.593756  1.149501
```

```
# above max_rows -> only min_rows (4) rows shown
```

```
In [33]: df = pd.DataFrame(np.random.randn(9, 2))
```

```
In [34]: df
```

```

`display.max_info_rows`: `df.info()` will usually show null-counts for each column. For large frames this can be quite slow. `max_info_rows` and `max_info_cols` limit this null check only to frames with smaller dimensions than specified. Note that you can specify the option `df.info(null_counts=True)` to override on showing a particular frame.

```
In [63]: df = pd.DataFrame(np.random.choice([0, 1, np.nan], size=(10, 10)))

3.17.5 Available options

Option	Default	Function
display.chop_threshold	None	If set to a float value, all float values smaller than the given threshold will be displayed as zero.
display.colheader_justify	right	Controls the justification of column headers. used by DataFrameFormatter.
display.column_space	12	No description available.
display.date_dayfirst	False	When True, prints and parses dates with the day first, eg 20/01/2005
display.date_yearfirst	False	When True, prints and parses dates with the year first, eg 2005/01/20
display.encoding	UTF-8	Defaults to the detected encoding of the console. Specifies the encoding to be used for output.
display.expand_frame_repr	True	Whether to print out the full DataFrame repr for wide DataFrames across multiple lines.
display.float_format	None	The callable should accept a floating point number and return a string with the desired representation.
display.large_repr	truncate	For DataFrames exceeding max_rows/max_cols, the repr (and HTML repr) can be truncated.
display.latex.repr	False	Whether to produce a latex DataFrame representation for jupyter frontends that support it.
display.latex.escape	True	Escapes special characters in DataFrames, when using the to_latex method.
display.latex.longtable	False	Specifies if the to_latex method of a DataFrame uses the longtable format.
display.latex.multiprint	True	Combines columns when using a MultiIndex
display.latex.multiprint_format	'T'	Alignment of multicolumn labels
display.latex.multirow	False	Combines rows when using a MultiIndex. Centered instead of top-aligned, separated by a blank line.
display.max_columns	0 or 20	max_rows and max_columns are used in __repr__() methods to decide if to_string() should be truncated.
display.max_colwidth	50	The maximum width in characters of a column in the repr of a pandas data structure.
display.max_info_columns	100	max_info_columns is used in DataFrame.info method to decide if per column info should be truncated.
display.max_info_rows	1690785	df.info() will usually show null-counts for each column. For large frames this can be truncated.
display.max_rows	60	This sets the maximum number of rows pandas should output when printing out a DataFrame.
display.min_rows	10	The numbers of rows to show in a truncated repr (when max_rows is exceeded).
display.max_seq_items	100	when pretty-printing a long sequence, no more than max_seq_items will be printed.

Option	Default	Function
display.memory_usage	True	This specifies if the memory usage of a DataFrame should be displayed when the “Sparsify” MultiIndex display (don’t display repeated elements in outer levels when they appear multiple times) is used.
display.multi_sparse	True	“Sparsify” MultiIndex display (don’t display repeated elements in outer levels when they appear multiple times).
display.notebook_repr_html	True	When True, IPython notebook will use html representation for pandas objects (e.g. DataFrames and Series).
display pprint_nest_depth	3	Controls the number of nested levels to process when pretty-printing.
display.precision	6	Floating point output precision in terms of number of places after the decimal, 1-15.
display.show_dimensions	truncate	Whether to print out dimensions at the end of DataFrame repr. If ‘truncate’ is specified, it will print the first and last few dimensions.
display.width	80	Width of the display in characters. In case python/IPython is running in a terminal, it is the width of the terminal window.
display.html.table_schema	False	Whether to publish a Table Schema representation for frontends that support it.
display.html.border	1	A border=value attribute is inserted in the <table> tag for the DataFrame repr.
display.html.use_mathjax	True	When True, Jupyter notebook will process table contents using MathJax, rendering them as mathematical expressions.
io.excel.xls.writer	xlwt	The default Excel writer engine for ‘xls’ files.
io.excel.xlsm.writer	openpyxl	The default Excel writer engine for ‘xlsm’ files. Available options: ‘openpyxl’ or ‘xlsm’.
io.excel.xlsx.writer	openpyxl	The default Excel writer engine for ‘xlsx’ files.
io.hdf.default_format	None	default format writing format, if None, then put will default to ‘fixed’ and append ‘.h5’.
io.hdf.dropna_table	True	drop ALL nan rows when appending to a table
io.parquet.engine	None	The engine to use as a default for parquet reading and writing. If None then try ‘pyarrow’.
mode.chained_assignment	warn	Controls SettingWithCopyWarning: ‘raise’, ‘warn’, or None. Raise an exception if ‘raise’.
mode.sim_interactive	False	Whether to simulate interactive mode for purposes of testing.
mode.use_inf_as_na	False	True means treat None, NaN, -INF, INF as NA (old way), False means None and -inf/inf are NA.
compute.use_bottleneck	True	Use the bottleneck library to accelerate computation if it is installed.
compute.use_numexpr	True	Use the numexpr library to accelerate computation if it is installed.
plotting.backend	matplotlib	Change the plotting backend to a different backend than the current matplotlib.
plotting.matplotlib.register_converters	True	Register custom converters with matplotlib. Set to False to de-register.

3.17.6 Number formatting

pandas also allows you to set how numbers are displayed in the console. This option is not set through the `set_options` API.

Use the `set_eng_float_format` function to alter the floating-point formatting of pandas objects to produce a particular format.

For instance:

```
In [87]: import numpy as np

In [88]: pd.set_eng_float_format(accuracy=3, use_eng_prefix=True)

In [89]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])

In [90]: s / 1.e3
Out[90]:
a    1.615m
b   -104.292u
c    -1.455m
d    927.500u
e   -17.229u
dtype: float64

In [91]: s / 1.e6
Out[91]:
a    1.615u
```

(continues on next page)

(continued from previous page)

```
b    -104.292n
c     -1.455u
d    927.500n
e    -17.229n
dtype: float64
```

To round floats on a case-by-case basis, you can also use `round()` and `round()`.

3.17.7 Unicode formatting

Warning: Enabling this option will affect the performance for printing of DataFrame and Series (about 2 times slower). Use only when it is actually required.

Some East Asian countries use Unicode characters whose width corresponds to two Latin characters. If a DataFrame or Series contains these characters, the default output mode may not align them properly.

Note: Screen captures are attached for each output to show the actual results.

```
In [92]: df = pd.DataFrame({'名前': ['Alice', ''], '国籍': ['UK', '']})

In [93]: df
Out[93]:
0   UK  Alice
1

>>> df = pd.DataFrame({u'国籍': ['UK', u'日本'], u'名前': ['Alice', u'しのぶ']})
>>> df
      名前 国籍
0  Alice  UK
1    しのぶ  日本
```

Enabling `display.unicode.east_asian_width` allows pandas to check each character's "East Asian Width" property. These characters can be aligned properly by setting this option to `True`. However, this will result in longer render times than the standard `len` function.

```
In [94]: pd.set_option('display.unicode.east_asian_width', True)

In [95]: df
Out[95]:
0      UK  Alice
1

>>> pd.set_option('display.unicode.east_asian_width', True)
>>> df
      名前 国籍
0  Alice  UK
1  しのぶ  日本
```

In addition, Unicode characters whose width is "Ambiguous" can either be 1 or 2 characters wide depending on the terminal setting or encoding. The option `display.unicode.ambiguous_as_wide` can be used to handle the ambiguity.

By default, an “Ambiguous” character’s width, such as “¡” (inverted exclamation) in the example below, is taken to be 1.

```
In [96]: df = pd.DataFrame({'a': ['xxx', '¡¡'], 'b': ['yyy', '¡¡']})
```

```
In [97]: df
```

```
Out[97]:
```

	a	b
0	xxx	yyy
1	¡¡	¡¡

```
>>> df = pd.DataFrame({'a': ['xxx', u'¡¡'], 'b': ['yyy', u'¡¡']})
```

```
>>> df
```

	a	b
0	xxx	yyy
1	¡¡	¡¡

Enabling `display.unicode.ambiguous_as_wide` makes pandas interpret these characters’ widths to be 2. (Note that this option will only be effective when `display.unicode.east_asian_width` is enabled.)

However, setting this option incorrectly for your terminal will cause these characters to be aligned incorrectly:

```
In [98]: pd.set_option('display.unicode.ambiguous_as_wide', True)
```

```
In [99]: df
```

```
Out[99]:
```

	a	b
0	xxx	yyy
1	¡¡	¡¡

```
>>> pd.set_option('display.unicode.ambiguous_as_wide', True)
```

```
>>> df
```

	a	b
0	xxx	yyy
1	¡¡	¡¡

3.17.8 Table schema display

`DataFrame` and `Series` will publish a Table Schema representation by default. False by default, this can be enabled globally with the `display.html.table_schema` option:

```
In [100]: pd.set_option('display.html.table_schema', True)
```

Only `'display.max_rows'` are serialized and published. {{ header }}

3.18 Enhancing performance

In this part of the tutorial, we will investigate how to speed up certain functions operating on pandas `DataFrames` using three different techniques: Cython, Numba and `pandas.eval()`. We will see a speed improvement of ~200 when we use Cython and Numba on a test function operating row-wise on the `DataFrame`. Using `pandas.eval()` we will speed up a sum by an order of ~2.

3.18.1 Cython (writing C extensions for pandas)

For many use cases writing pandas in pure Python and NumPy is sufficient. In some computationally heavy applications however, it can be possible to achieve sizable speed-ups by offloading work to [cython](#).

This tutorial assumes you have refactored as much as possible in Python, for example by trying to remove for-loops and making use of NumPy vectorization. It's always worth optimising in Python first.

This tutorial walks through a “typical” process of cythonizing a slow computation. We use an [example](#) from the [Cython documentation](#) but in the context of pandas. Our final cythonized solution is around 100 times faster than the pure Python solution.

Pure Python

We have a DataFrame to which we want to apply a function row-wise.

```
In [1]: df = pd.DataFrame({'a': np.random.randn(1000),
...:                      'b': np.random.randn(1000),
...:                      'N': np.random.randint(100, 1000, 1000)),
...:                      'x': 'x'})
...:

In [2]: df
Out[2]:
      a        b     N   x
0 -0.875803  0.293370  953  x
1 -0.405186  0.908524  242  x
2 -0.532721  0.037825  986  x
3 -0.087214  0.961076  902  x
4 -0.629603 -0.172846  291  x
...
995 -0.065791 -1.319324  868  x
996 -0.239639  1.558266  139  x
997  0.429888  0.593019  576  x
998  0.512960  0.856262  146  x
999  1.171391 -0.250933  230  x

[1000 rows x 4 columns]
```

Here's the function in pure Python:

```
In [3]: def f(x):
...:     return x * (x - 1)
...:

In [4]: def integrate_f(a, b, N):
...:     s = 0
...:     dx = (b - a) / N
...:     for i in range(N):
...:         s += f(a + i * dx)
...:     return s * dx
...:
```

We achieve our result by using `apply` (row-wise):

```
In [7]: %timeit df.apply(lambda x: integrate_f(x['a'], x['b'], x['N']), axis=1)
10 loops, best of 3: 174 ms per loop
```

But clearly this isn't fast enough for us. Let's take a look and see where the time is spent during this operation (limited to the most time consuming four calls) using the `prun` ipython magic function:

```
In [5]: %prun -l 4 df.apply(lambda x: integrate_f(x['a'], x['b'], x['N']), axis=1) #_  
↳noqa E999  
    702706 function calls (699680 primitive calls) in 0.313 seconds  
  
Ordered by: internal time  
List reduced from 227 to 4 due to restriction <4>  
  
      ncalls  tottime  percall  cumtime  percall filename:lineno(function)  
        1000    0.148    0.000    0.224    0.000 <ipython-input-4-c2a74e076cf0>:  
→1(integrate_f)  
  553907    0.076    0.000    0.076    0.000 <ipython-input-3-c138bdd570e3>:1(f)  
   3000    0.008    0.000    0.071    0.000 base.py:4373(get_value)  
  18363    0.007    0.000    0.013    0.000 {built-in method builtins.isinstance}
```

By far the majority of time is spend inside either `integrate_f` or `f`, hence we'll concentrate our efforts cythonizing these two functions.

Note: In Python 2 replacing the `range` with its generator counterpart (`xrange`) would mean the `range` line would vanish. In Python 3 `range` is already a generator.

Plain Cython

First we're going to need to import the Cython magic function to ipython:

```
In [6]: %load_ext Cython
```

Now, let's simply copy our functions over to Cython as is (the suffix is here to distinguish between function versions):

```
In [7]: %%cython  
....: def f_plain(x):  
....:     return x * (x - 1)  
....: def integrate_f_plain(a, b, N):  
....:     s = 0  
....:     dx = (b - a) / N  
....:     for i in range(N):  
....:         s += f_plain(a + i * dx)  
....:     return s * dx  
....:
```

Note: If you're having trouble pasting the above into your ipython, you may need to be using bleeding edge ipython for paste to play well with cell magics.

```
In [4]: %timeit df.apply(lambda x: integrate_f_plain(x['a'], x['b'], x['N']), axis=1)  
10 loops, best of 3: 85.5 ms per loop
```

Already this has shaved a third off, not too bad for a simple copy and paste.

Adding type

We get another huge improvement simply by providing type information:

```
In [8]: %%cython
....: cdef double f_typed(double x) except? -2:
....:     return x * (x - 1)
....: cpdef double integrate_f_typed(double a, double b, int N):
....:     cdef int i
....:     cdef double s, dx
....:     s = 0
....:     dx = (b - a) / N
....:     for i in range(N):
....:         s += f_typed(a + i * dx)
....:     return s * dx
....:
```

```
In [4]: %timeit df.apply(lambda x: integrate_f_typed(x['a'], x['b'], x['N']), axis=1)
10 loops, best of 3: 20.3 ms per loop
```

Now, we're talking! It's now over ten times faster than the original python implementation, and we haven't *really* modified the code. Let's have another look at what's eating up time:

```
In [9]: %prun -l 4 df.apply(lambda x: integrate_f_typed(x['a'], x['b'], x['N']), axis=1)
148795 function calls (145769 primitive calls) in 0.081 seconds

Ordered by: internal time
List reduced from 222 to 4 due to restriction <4>

ncalls  tottime  percall  cumtime  percall filename:lineno(function)
    3000    0.008    0.000    0.066    0.000 base.py:4373(get_value)
 18363    0.006    0.000    0.012    0.000 {built-in method builtins.isinstance}
    6001    0.005    0.000    0.012    0.000 {pandas._libs.lib.values_from_object}
    3000    0.005    0.000    0.008    0.000 numpy_.py:138(__init__)
```

Using ndarray

It's calling series... a lot! It's creating a Series from each row, and get-ting from both the index and the series (three times for each row). Function calls are expensive in Python, so maybe we could minimize these by cythonizing the apply part.

Note: We are now passing ndarrays into the Cython function, fortunately Cython plays very nicely with NumPy.

```
In [10]: %%cython
....: cimport numpy as np
....: import numpy as np
....: cdef double f_typed(double x) except? -2:
....:     return x * (x - 1)
....: cpdef double integrate_f_typed(double a, double b, int N):
....:     cdef int i
....:     cdef double s, dx
....:     s = 0
....:     dx = (b - a) / N
```

(continues on next page)

(continued from previous page)

```

....:     for i in range(N):
....:         s += f_typed(a + i * dx)
....:     return s * dx
....: cpdef np.ndarray[double] apply_integrate_f(np.ndarray col_a, np.ndarray col_
↪b,
....:                                             np.ndarray col_N):
....:     assert (col_a.dtype == np.float
....:            and col_b.dtype == np.float and col_N.dtype == np.int)
....:     cdef Py_ssize_t i, n = len(col_N)
....:     assert (len(col_a) == len(col_b) == n)
....:     cdef np.ndarray[double] res = np.empty(n)
....:     for i in range(len(col_a)):
....:         res[i] = integrate_f_typed(col_a[i], col_b[i], col_N[i])
....:     return res
....:

```

The implementation is simple, it creates an array of zeros and loops over the rows, applying our `integrate_f_typed`, and putting this in the zeros array.

Warning: You can **not** pass a Series directly as a ndarray typed parameter to a Cython function. Instead pass the actual ndarray using the `Series.to_numpy()`. The reason is that the Cython definition is specific to an ndarray and not the passed Series.

So, do not do this:

```
apply_integrate_f(df['a'], df['b'], df['N'])
```

But rather, use `Series.to_numpy()` to get the underlying ndarray:

```
apply_integrate_f(df['a'].to_numpy(),
                  df['b'].to_numpy(),
                  df['N'].to_numpy())
```

Note: Loops like this would be *extremely* slow in Python, but in Cython looping over NumPy arrays is *fast*.

```
In [4]: %timeit apply_integrate_f(df['a'].to_numpy(),
                                 df['b'].to_numpy(),
                                 df['N'].to_numpy())
1000 loops, best of 3: 1.25 ms per loop
```

We've gotten another big improvement. Let's check again where the time is spent:

```
In [11]: %%prun -l 4 apply_integrate_f(df['a'].to_numpy(),
                                         df['b'].to_numpy(),
                                         df['N'].to_numpy())
....:
260 function calls in 0.002 seconds

Ordered by: internal time
List reduced from 65 to 4 due to restriction <4>

ncalls  tottime  percall  cumtime  percall filename:lineno(function)
      1    0.001    0.001    0.001    0.001 {built-in method __cython_magic_
↪_apply_integrate_f}
```

(continues on next page)

(continued from previous page)

1	0.000	0.000	0.002	0.002 {built-in method builtins.exec}
3	0.000	0.000	0.000	0.000 frame.py:2767(__getitem__)
3	0.000	0.000	0.000	0.000 managers.py:979(iget)

As one might expect, the majority of the time is now spent in `apply_integrate_f`, so if we wanted to make anymore efficiencies we must continue to concentrate our efforts here.

More advanced techniques

There is still hope for improvement. Here's an example of using some more advanced Cython techniques:

```
In [12]: %%cython
....: cimport cython
....: cimport numpy as np
....: import numpy as np
....: cdef double f_typed(double x) except? -2:
....:     return x * (x - 1)
....: cpdef double integrate_f_typed(double a, double b, int N):
....:     cdef int i
....:     cdef double s, dx
....:     s = 0
....:     dx = (b - a) / N
....:     for i in range(N):
....:         s += f_typed(a + i * dx)
....:     return s * dx
....: #cython.boundscheck(False)
....: #cython.wraparound(False)
....: cpdef np.ndarray[double] apply_integrate_f_wrap(np.ndarray[double] col_a,
....:                                                 np.ndarray[double] col_b,
....:                                                 np.ndarray[int] col_N):
....:     cdef int i, n = len(col_N)
....:     assert len(col_a) == len(col_b) == n
....:     cdef np.ndarray[double] res = np.empty(n)
....:     for i in range(n):
....:         res[i] = integrate_f_typed(col_a[i], col_b[i], col_N[i])
....:     return res
....:
```

```
In [4]: %timeit apply_integrate_f_wrap(df['a'].to_numpy(),
                                         df['b'].to_numpy(),
                                         df['N'].to_numpy())
1000 loops, best of 3: 987 us per loop
```

Even faster, with the caveat that a bug in our Cython code (an off-by-one error, for example) might cause a segfault because memory access isn't checked. For more about boundscheck and wraparound, see the Cython docs on compiler directives.

3.18.2 Using Numba

A recent alternative to statically compiling Cython code, is to use a *dynamic jit-compiler*, Numba.

Numba gives you the power to speed up your applications with high performance functions written directly in Python. With a few annotations, array-oriented and math-heavy Python code can be just-in-time compiled to native machine instructions, similar in performance to C, C++ and Fortran, without having to switch languages or Python interpreters.

Numba works by generating optimized machine code using the LLVM compiler infrastructure at import time, runtime, or statically (using the included pycc tool). Numba supports compilation of Python to run on either CPU or GPU hardware, and is designed to integrate with the Python scientific software stack.

Note: You will need to install Numba. This is easy with conda, by using: `conda install numba`, see [installing using miniconda](#).

Note: As of Numba version 0.20, pandas objects cannot be passed directly to Numba-compiled functions. Instead, one must pass the NumPy array underlying the pandas object to the Numba-compiled function as demonstrated below.

Jit

We demonstrate how to use Numba to just-in-time compile our code. We simply take the plain Python code from above and annotate with the `@jit` decorator.

```
import numba

@numba.jit
def f_plain(x):
    return x * (x - 1)

@numba.jit
def integrate_f_numba(a, b, N):
    s = 0
    dx = (b - a) / N
    for i in range(N):
        s += f_plain(a + i * dx)
    return s * dx

@numba.jit
def apply_integrate_f_numba(col_a, col_b, col_N):
    n = len(col_N)
    result = np.empty(n, dtype='float64')
    assert len(col_a) == len(col_b) == n
    for i in range(n):
        result[i] = integrate_f_numba(col_a[i], col_b[i], col_N[i])
    return result

def compute_numba(df):
    result = apply_integrate_f_numba(df['a'].to_numpy(),
                                    df['b'].to_numpy(),
```

(continues on next page)

(continued from previous page)

```
        df['N'].to_numpy())
    return pd.Series(result, index=df.index, name='result')
```

Note that we directly pass NumPy arrays to the Numba function. `compute_numba` is just a wrapper that provides a nicer interface by passing/returning pandas objects.

```
In [4]: %timeit compute_numba(df)
1000 loops, best of 3: 798 us per loop
```

In this example, using Numba was faster than Cython.

Vectorize

Numba can also be used to write vectorized functions that do not require the user to explicitly loop over the observations of a vector; a vectorized function will be applied to each row automatically. Consider the following toy example of doubling each observation:

```
import numba

def double_every_value_nonumba(x):
    return x * 2

@numba.vectorize
def double_every_value_withnumba(x):    # noqa E501
    return x * 2

# Custom function without numba
In [5]: %timeit df['col1_doubled'] = df['a'].apply(double_every_value_nonumba)  #_
          ↪noqa E501
1000 loops, best of 3: 797 us per loop

# Standard implementation (faster than a custom function)
In [6]: %timeit df['col1_doubled'] = df['a'] * 2
1000 loops, best of 3: 233 us per loop

# Custom function with numba
In [7]: %timeit (df['col1_doubled']) = double_every_value_withnumba(df['a'].to_numpy())
1000 loops, best of 3: 145 us per loop
```

Caveats

Note: Numba will execute on any function, but can only accelerate certain classes of functions.

Numba is best at accelerating functions that apply numerical functions to NumPy arrays. When passed a function that only uses operations it knows how to accelerate, it will execute in `nopython` mode.

If Numba is passed a function that includes something it doesn't know how to work with – a category that currently includes sets, lists, dictionaries, or string functions – it will revert to `object` mode. In `object` mode, Numba will execute but your code will not speed up significantly. If you would prefer that Numba throw an error if it cannot

compile a function in a way that speeds up your code, pass Numba the argument `nopython=True` (e.g. `@numba.jit(nopython=True)`). For more on troubleshooting Numba modes, see the [Numba troubleshooting page](#).

Read more in the [Numba docs](#).

3.18.3 Expression evaluation via `eval()`

The top-level function `pandas.eval()` implements expression evaluation of `Series` and `DataFrame` objects.

Note: To benefit from using `eval()` you need to install `numexpr`. See the [recommended dependencies section](#) for more details.

The point of using `eval()` for expression evaluation rather than plain Python is two-fold: 1) large `DataFrame` objects are evaluated more efficiently and 2) large arithmetic and boolean expressions are evaluated all at once by the underlying engine (by default `numexpr` is used for evaluation).

Note: You should not use `eval()` for simple expressions or for expressions involving small DataFrames. In fact, `eval()` is many orders of magnitude slower for smaller expressions/objects than plain ol' Python. A good rule of thumb is to only use `eval()` when you have a DataFrame with more than 10,000 rows.

`eval()` supports all arithmetic expressions supported by the engine in addition to some extensions available only in pandas.

Note: The larger the frame and the larger the expression the more speedup you will see from using `eval()`.

Supported syntax

These operations are supported by `pandas.eval()`:

- Arithmetic operations except for the left shift (`<<`) and right shift (`>>`) operators, e.g., `df + 2 * pi / s ** 4 % 42 - the_golden_ratio`
- Comparison operations, including chained comparisons, e.g., `2 < df < df2`
- Boolean operations, e.g., `df < df2` and `df3 < df4` or `not df_bool`
- list and tuple literals, e.g., `[1, 2]` or `(1, 2)`
- Attribute access, e.g., `df.a`
- Subscript expressions, e.g., `df[0]`
- Simple variable evaluation, e.g., `pd.eval('df')` (this is not very useful)
- Math functions: `sin, cos, exp, log, expm1, log1p, sqrt, sinh, cosh, tanh, arcsin, arccos, arctan, arccosh, arcsinh, arctanh, abs, arctan2` and `log10`.

This Python syntax is **not** allowed:

- Expressions
 - Function calls other than math functions.
 - `is/is not` operations
 - `if` expressions

- lambda expressions
 - list/set/dict comprehensions
 - Literal dict and set expressions
 - yield expressions
 - Generator expressions
 - Boolean expressions consisting of only scalar values
- Statements
 - Neither `simple` nor `compound` statements are allowed. This includes things like `for`, `while`, and `if`.

`eval()` examples

`pandas.eval()` works well with expressions containing large arrays.

First let's create a few decent-sized arrays to play with:

```
In [13]: nrows, ncols = 20000, 100  
  
In [14]: df1, df2, df3, df4 = [pd.DataFrame(np.random.randn(nrows, ncols)) for _ in  
    ↪range(4)]
```

Now let's compare adding them together using plain ol' Python versus `eval()`:

```
In [15]: %timeit df1 + df2 + df3 + df4  
16.4 ms +- 1.52 ms per loop (mean +- std. dev. of 7 runs, 100 loops each)  
  
In [16]: %timeit pd.eval('df1 + df2 + df3 + df4')  
7.74 ms +- 796 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

Now let's do the same thing but with comparisons:

```
In [17]: %timeit (df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0)  
111 ms +- 995 us per loop (mean +- std. dev. of 7 runs, 10 loops each)  
  
In [18]: %timeit pd.eval('(df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0)')  
13 ms +- 864 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

`eval()` also works with unaligned pandas objects:

```
In [19]: s = pd.Series(np.random.randn(50))  
  
In [20]: %timeit df1 + df2 + df3 + df4 + s  
104 ms +- 9.81 ms per loop (mean +- std. dev. of 7 runs, 10 loops each)  
  
In [21]: %timeit pd.eval('df1 + df2 + df3 + df4 + s')  
10.5 ms +- 1.22 ms per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

Note: Operations such as

```
1 and 2 # would parse to 1 & 2, but should evaluate to 2  
3 or 4 # would parse to 3 | 4, but should evaluate to 3  
~1 # this is okay, but slower when using eval
```

should be performed in Python. An exception will be raised if you try to perform any boolean/bitwise operations with scalar operands that are not of type `bool` or `np.bool_`. Again, you should perform these kinds of operations in plain Python.

The `DataFrame.eval` method

In addition to the top level `pandas.eval()` function you can also evaluate an expression in the “context” of a `DataFrame`.

```
In [22]: df = pd.DataFrame(np.random.randn(5, 2), columns=['a', 'b'])

In [23]: df.eval('a + b')
Out[23]:
0    0.273125
1   -0.163827
2   -1.129232
3    1.926287
4    2.019457
dtype: float64
```

Any expression that is a valid `pandas.eval()` expression is also a valid `DataFrame.eval()` expression, with the added benefit that you don’t have to prefix the name of the `DataFrame` to the column(s) you’re interested in evaluating.

In addition, you can perform assignment of columns within an expression. This allows for *formulaic evaluation*. The assignment target can be a new column name or an existing column name, and it must be a valid Python identifier.

The `inplace` keyword determines whether this assignment will be performed on the original `DataFrame` or return a copy with the new column.

Warning: For backwards compatibility, `inplace` defaults to `True` if not specified. This will change in a future version of pandas - if your code depends on an `inplace` assignment you should update to explicitly set `inplace=True`.

```
In [24]: df = pd.DataFrame(dict(a=range(5), b=range(5, 10)))

In [25]: df.eval('c = a + b', inplace=True)

In [26]: df.eval('d = a + b + c', inplace=True)

In [27]: df.eval('a = 1', inplace=True)

In [28]: df
Out[28]:
   a   b   c   d
0  1   5   5  10
1  1   6   7  14
2  1   7   9  18
3  1   8  11  22
4  1   9  13  26
```

When `inplace` is set to `False`, a copy of the `DataFrame` with the new or modified columns is returned and the original frame is unchanged.

```
In [29]: df
Out[29]:
   a   b   c   d
0  1   5   5  10
1  1   6   7  14
2  1   7   9  18
3  1   8  11  22
4  1   9  13  26
```

```
In [30]: df.eval('e = a - c', inplace=False)
```

```
Out[30]:
   a   b   c   d   e
0  1   5   5  10  -4
1  1   6   7  14  -6
2  1   7   9  18  -8
3  1   8  11  22 -10
4  1   9  13  26 -12
```

```
In [31]: df
```

```
Out[31]:
   a   b   c   d
0  1   5   5  10
1  1   6   7  14
2  1   7   9  18
3  1   8  11  22
4  1   9  13  26
```

As a convenience, multiple assignments can be performed by using a multi-line string.

```
In [32]: df.eval("""
....: c = a + b
....: d = a + b + c
....: a = 1""", inplace=False)
....:
```

```
Out[32]:
   a   b   c   d
0  1   5   6  12
1  1   6   7  14
2  1   7   8  16
3  1   8   9  18
4  1   9  10  20
```

The equivalent in standard Python would be

```
In [33]: df = pd.DataFrame(dict(a=range(5), b=range(5, 10)))
```

```
In [34]: df['c'] = df['a'] + df['b']
```

```
In [35]: df['d'] = df['a'] + df['b'] + df['c']
```

```
In [36]: df['a'] = 1
```

```
In [37]: df
```

```
Out[37]:
   a   b   c   d
0  1   5   5  10
1  1   6   7  14
```

(continues on next page)

(continued from previous page)

2	1	7	9	18
3	1	8	11	22
4	1	9	13	26

The `query` method has a `inplace` keyword which determines whether the query modifies the original frame.

```
In [38]: df = pd.DataFrame(dict(a=range(5), b=range(5, 10)))
```

```
In [39]: df.query('a > 2')
```

```
Out[39]:
```

a	b
3	3
4	4

```
In [40]: df.query('a > 2', inplace=True)
```

```
In [41]: df
```

```
Out[41]:
```

a	b
3	3
4	9

Warning: Unlike with `eval`, the default value for `inplace` for `query` is `False`. This is consistent with prior versions of pandas.

Local variables

You must *explicitly reference* any local variable that you want to use in an expression by placing the `@` character in front of the name. For example,

```
In [42]: df = pd.DataFrame(np.random.randn(5, 2), columns=list('ab'))
```

```
In [43]: newcol = np.random.randn(len(df))
```

```
In [44]: df.eval('b + @newcol')
```

```
Out[44]:
```

0	1.083828
1	-1.017795
2	-0.887217
3	2.561401
4	-2.338813

dtype: float64

```
In [45]: df.query('b < @newcol')
```

```
Out[45]:
```

	a	b
0	-0.634219	-0.399430
2	-0.521304	-1.334155
3	-1.096405	1.182902

If you don't prefix the local variable with `@`, pandas will raise an exception telling you the variable is undefined.

When using `DataFrame.eval()` and `DataFrame.query()`, this allows you to have a local variable and a `DataFrame` column with the same name in an expression.

```
In [46]: a = np.random.randn()

In [47]: df.query('@a < a')
Out[47]:
      a          b
4  0.869889 -0.836686

In [48]: df.loc[a < df['a']]  # same as the previous expression
Out[48]:
      a          b
4  0.869889 -0.836686
```

With `pandas.eval()` you cannot use the `@` prefix *at all*, because it isn't defined in that context. pandas will let you know this if you try to use `@` in a top-level call to `pandas.eval()`. For example,

```
In [49]: a, b = 1, 2

In [50]: pd.eval('@a + b')
Traceback (most recent call last):

  File "/opt/conda/envs/pandas/lib/python3.7/site-packages/IPython/core/
  ↪interactiveshell.py", line 3331, in run_code
    exec(code_obj, self.user_global_ns, self.user_ns)

  File "<ipython-input-50-af17947a194f>", line 1, in <module>
    pd.eval('@a + b')

  File "/pandas/pandas/core/computation/eval.py", line 321, in eval
    _check_for_locals(expr, level, parser)

  File "/pandas/pandas/core/computation/eval.py", line 167, in _check_for_locals
    raise SyntaxError(msg)

  File "<string>", line unknown
SyntaxError: The '@' prefix is not allowed in top-level eval calls,
please refer to your variables by name without the '@' prefix
```

In this case, you should simply refer to the variables like you would in standard Python.

```
In [51]: pd.eval('a + b')
Out[51]: 3
```

pandas.eval() parsers

There are two different parsers and two different engines you can use as the backend.

The default 'pandas' parser allows a more intuitive syntax for expressing query-like operations (comparisons, conjunctions and disjunctions). In particular, the precedence of the `&` and `|` operators is made equal to the precedence of the corresponding boolean operations `and` and `or`.

For example, the above conjunction can be written without parentheses. Alternatively, you can use the 'python' parser to enforce strict Python semantics.

```
In [52]: expr = '(df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0)'

In [53]: x = pd.eval(expr, parser='python')
```

(continues on next page)

(continued from previous page)

```
In [54]: expr_no_parens = 'df1 > 0 & df2 > 0 & df3 > 0 & df4 > 0'

In [55]: y = pd.eval(expr_no_parens, parser='pandas')

In [56]: np.all(x == y)
Out[56]: True
```

The same expression can be “anded” together with the word `and` as well:

```
In [57]: expr = '(df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0)'

In [58]: x = pd.eval(expr, parser='python')

In [59]: expr_with_ands = 'df1 > 0 and df2 > 0 and df3 > 0 and df4 > 0'

In [60]: y = pd.eval(expr_with_ands, parser='pandas')

In [61]: np.all(x == y)
Out[61]: True
```

The `and` and `or` operators here have the same precedence that they would in vanilla Python.

pandas.eval() backends

There’s also the option to make `eval()` operate identical to plain ol’ Python.

Note: Using the ‘python’ engine is generally *not* useful, except for testing other evaluation engines against it. You will achieve **no** performance benefits using `eval()` with `engine='python'` and in fact may incur a performance hit.

You can see this by using `pandas.eval()` with the ‘python’ engine. It is a bit slower (not by much) than evaluating the same expression in Python

```
In [62]: %timeit df1 + df2 + df3 + df4
15.7 ms +- 1.05 ms per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

```
In [63]: %timeit pd.eval('df1 + df2 + df3 + df4', engine='python')
17.3 ms +- 1.37 ms per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

pandas.eval() performance

`eval()` is intended to speed up certain kinds of operations. In particular, those operations involving complex expressions with large `DataFrame/Series` objects should see a significant performance benefit. Here is a plot showing the running time of `pandas.eval()` as function of the size of the frame involved in the computation. The two lines are two different engines.

Note: Operations with smallish objects (around 15k-20k rows) are faster using plain Python:

This plot was created using a `DataFrame` with 3 columns each containing floating point values generated using `numpy.random.randn()`.

Technical minutia regarding expression evaluation

Expressions that would result in an object dtype or involve datetime operations (because of NaT) must be evaluated in Python space. The main reason for this behavior is to maintain backwards compatibility with versions of NumPy < 1.7. In those versions of NumPy a call to `ndarray.astype(str)` will truncate any strings that are more than 60 characters in length. Second, we can't pass object arrays to `numexpr` thus string comparisons must be evaluated in Python space.

The upshot is that this *only* applies to object-dtype expressions. So, if you have an expression—for example

```
In [64]: df = pd.DataFrame({'strings': np.repeat(list('cba'), 3),
   ....:                  'nums': np.repeat(range(3), 3)})
....:

In [65]: df
Out[65]:
   strings  nums
0         c     0
1         c     0
2         c     0
3         b     1
4         b     1
5         b     1
6         a     2
7         a     2
8         a     2

In [66]: df.query('strings == "a" and nums == 1')
Out[66]:
Empty DataFrame
Columns: [strings, nums]
Index: []
```

the numeric part of the comparison (`nums == 1`) will be evaluated by `numexpr`.

In general, `DataFrame.query()`/`pandas.eval()` will evaluate the subexpressions that *can* be evaluated by `numexpr` and those that must be evaluated in Python space transparently to the user. This is done by inferring the result type of an expression from its arguments and operators.

3.19 Scaling to large datasets

Pandas provides data structures for in-memory analytics, which makes using pandas to analyze datasets that are larger than memory datasets somewhat tricky. Even datasets that are a sizable fraction of memory become unwieldy, as some pandas operations need to make intermediate copies.

This document provides a few recommendations for scaling your analysis to larger datasets. It's a complement to `enhancingperf`, which focuses on speeding up analysis for datasets that fit in memory.

But first, it's worth considering *not using pandas*. Pandas isn't the right tool for all situations. If you're working with very large datasets and a tool like PostgreSQL fits your needs, then you should probably be using that. Assuming you want or need the expressiveness and power of pandas, let's carry on.

```
In [1]: import pandas as pd

In [2]: import numpy as np
```

3.19.1 Load less data

Suppose our raw dataset on disk has many columns:

	id_0	name_0	x_0	y_0	id_1	name_1	x_1	...
↳ name_8	x_8	y_8	id_9	name_9	x_9	y_9

2000-12-30 23:58:00	1065	Edith	0.232211	-0.454540
2000-12-30 23:59:00	1019	Ingrid	0.322208	-0.615974
2000-12-31 00:00:00	937	Ursula	-0.906523	0.943178

[525601 rows x 4 columns]

If we were to measure the memory usage of the two calls, we'd see that specifying `columns` uses about 1/10th the memory in this case.

With `pandas.read_csv()`, you can specify `usecols` to limit the columns read into memory. Not all file formats that can be read by pandas provide an option to read a subset of columns.

3.19.2 Use efficient datatypes

The default pandas data types are not the most memory efficient. This is especially true for text data columns with relatively few unique values (commonly referred to as “low-cardinality” data). By using more efficient data types, you can store larger datasets in memory.

In [6]:	ts = pd.read_parquet("timeseries.parquet")			
In [7]:	ts			
Out[7]:				
	id name x y			
timestamp				
2000-01-01 00:00:00	1029	Michael	0.278837	0.247932
2000-01-01 00:00:30	1010	Patricia	0.077144	0.490260
2000-01-01 00:01:00	1001	Victor	0.214525	0.258635
2000-01-01 00:01:30	1018	Alice	-0.646866	0.822104
2000-01-01 00:02:00	991	Dan	0.902389	0.466665
...
2000-12-30 23:58:00	992	Sarah	0.721155	0.944118
2000-12-30 23:58:30	1007	Ursula	0.409277	0.133227
2000-12-30 23:59:00	1009	Hannah	-0.452802	0.184318
2000-12-30 23:59:30	978	Kevin	-0.904728	-0.179146
2000-12-31 00:00:00	973	Ingrid	-0.370763	-0.794667

[1051201 rows x 4 columns]

Now, let's inspect the data types and memory usage to see where we should focus our attention.

In [8]:	ts.dtypes
Out[8]:	
id	int64
name	object
x	float64

(continues on next page)

(continued from previous page)

```
y      float64  
dtype: object
```

```
In [9]: ts.memory_usage(deep=True)    # memory usage in bytes  
Out[9]:  
Index      8409608  
id        8409608  
name     65537768  
x         8409608  
y         8409608  
dtype: int64
```

The name column is taking up much more memory than any other. It has just a few unique values, so it's a good candidate for converting to a Categorical. With a Categorical, we store each unique name once and use space-efficient integers to know which specific name is used in each row.

```
In [10]: ts2 = ts.copy()  
  
In [11]: ts2['name'] = ts2['name'].astype('category')  
  
In [12]: ts2.memory_usage(deep=True)  
Out[12]:  
Index      8409608  
id        8409608  
name     1054102  
x         8409608  
y         8409608  
dtype: int64
```

We can go a bit further and downcast the numeric columns to their smallest types using `pandas.to_numeric()`.

```
In [13]: ts2['id'] = pd.to_numeric(ts2['id'], downcast='unsigned')  
  
In [14]: ts2[['x', 'y']] = ts2[['x', 'y']].apply(pd.to_numeric, downcast='float')  
  
In [15]: ts2.dtypes  
Out[15]:  
id        uint16  
name     category  
x       float32  
y       float32  
dtype: object
```

```
In [16]: ts2.memory_usage(deep=True)  
Out[16]:  
Index      8409608  
id        2102402  
name     1054102  
x         4204804  
y         4204804  
dtype: int64
```

```
In [17]: reduction = (ts2.memory_usage(deep=True).sum()  
....:             / ts.memory_usage(deep=True).sum())  
....:
```

(continues on next page)

(continued from previous page)

```
In [18]: print(f" {reduction:.0f} ")
0.20
```

In all, we've reduced the in-memory footprint of this dataset to 1/5 of its original size.

See `categorical` for more on `Categorical` and `dtypes` for an overview of all of pandas' dtypes.

3.19.3 Use chunking

Some workloads can be achieved with chunking: splitting a large problem like “convert this directory of CSVs to parquet” into a bunch of small problems (“convert this individual CSV file into a Parquet file. Now repeat that for each file in this directory.”). As long as each chunk fits in memory, you can work with datasets that are much larger than memory.

Note: Chunking works well when the operation you're performing requires zero or minimal coordination between chunks. For more complicated workflows, you're better off [using another library](#).

Suppose we have an even larger “logical dataset” on disk that's a directory of parquet files. Each file in the directory represents a different year of the entire dataset.

```
data
└── timeseries
    ├── ts-00.parquet
    ├── ts-01.parquet
    ├── ts-02.parquet
    ├── ts-03.parquet
    ├── ts-04.parquet
    ├── ts-05.parquet
    ├── ts-06.parquet
    ├── ts-07.parquet
    ├── ts-08.parquet
    ├── ts-09.parquet
    ├── ts-10.parquet
    └── ts-11.parquet
```

Now we'll implement an out-of-core `value_counts`. The peak memory usage of this workflow is the single largest chunk, plus a small series storing the unique value counts up to this point. As long as each individual file fits in memory, this will work for arbitrary-sized datasets.

```
In [19]: %%time
....: files = pathlib.Path("data/timeseries/").glob("ts*.parquet")
....: counts = pd.Series(dtype=int)
....: for path in files:
....:     df = pd.read_parquet(path)
....:     counts = counts.add(df['name'].value_counts(), fill_value=0)
....: counts.astype(int)
....:
CPU times: user 2.34 s, sys: 396 ms, total: 2.74 s
Wall time: 2.69 s
Out[19]:
Alice      229802
Bob       229211
```

(continues on next page)

(continued from previous page)

```
Charlie      229303
Dan         230621
Edith       230349
Frank        230595
George       230594
Hannah       230530
Ingrid       230838
Jerry        229961
Kevin        230698
Laura        230906
Michael      230504
Norbert      230197
Oliver       230264
Patricia     229699
Quinn        229809
Ray          229603
Sarah        229826
Tim          230542
Ursula       230592
Victor       230502
Wendy        230038
Xavier       229553
Yvonne       228766
Zelda        229909
dtype: int64
```

Some readers, like `pandas.read_csv()`, offer parameters to control the `chunksize` when reading a single file.

Manually chunking is an OK option for workflows that don't require too sophisticated of operations. Some operations, like `groupby`, are much harder to do chunkwise. In these cases, you may be better switching to a different library that implements these out-of-core algorithms for you.

3.19.4 Use other libraries

Pandas is just one library offering a DataFrame API. Because of its popularity, pandas' API has become something of a standard that other libraries implement. The pandas documentation maintains a list of libraries implementing a DataFrame API in our ecosystem page.

For example, `Dask`, a parallel computing library, has `dask.dataframe`, a pandas-like API for working with larger than memory datasets in parallel. Dask can use multiple threads or processes on a single machine, or a cluster of machines to process data in parallel.

We'll import `dask.dataframe` and notice that the API feels similar to pandas. We can use Dask's `read_parquet` function, but provide a globstring of files to read in.

```
In [20]: import dask.dataframe as dd

In [21]: ddf = dd.read_parquet("data/timeseries/ts*.parquet", engine="pyarrow")

In [22]: ddf
Out[22]:
Dask DataFrame Structure:
      id      name          x          y
npartitions=12
           int64  object  float64  float64
              ...     ...      ...      ...

```

(continues on next page)

(continued from previous page)

```
...
...
...
...
...
Dask Name: read-parquet, 12 tasks
```

Inspecting the `ddf` object, we see a few things

- There are familiar attributes like `.columns` and `.dtypes`
- There are familiar methods like `.groupby`, `.sum`, etc.
- There are new attributes like `.npartitions` and `.divisions`

The partitions and divisions are how Dask parallelizes computation. A **Dask DataFrame** is made up of many **Pandas DataFrames**. A single method call on a Dask DataFrame ends up making many pandas method calls, and Dask knows how to coordinate everything to get the result.

```
In [23]: ddf.columns
Out[23]: Index(['id', 'name', 'x', 'y'], dtype='object')

In [24]: ddf.dtypes
Out[24]:
id      int64
name    object
x       float64
y       float64
dtype: object

In [25]: ddf.npartitions
Out[25]: 12
```

One major difference: the `dask.dataframe` API is *lazy*. If you look at the repr above, you'll notice that the values aren't actually printed out; just the column names and dtypes. That's because Dask hasn't actually read the data yet. Rather than executing immediately, doing operations build up a **task graph**.

```
In [26]: ddf
Out[26]:
Dask DataFrame Structure:
      id      name          x          y
npartitions=12
      int64  object  float64  float64
      ...
      ...
      ...
      ...
      ...
Dask Name: read-parquet, 12 tasks

In [27]: ddf['name']
Out[27]:
Dask Series Structure:
npartitions=12
      object
      ...
      ...
      ...
      ...
Name: name, dtype: object
Dask Name: getitem, 24 tasks
```

(continues on next page)

(continued from previous page)

```
In [28]: ddf['name'].value_counts()
Out[28]:
Dask Series Structure:
npartitions=1
  int64
  ...
Name: name, dtype: int64
Dask Name: value-counts-agg, 39 tasks
```

Each of these calls is instant because the result isn't being computed yet. We're just building up a list of computation to do when someone needs the result. Dask knows that the return type of a pandas.Series.value_counts is a pandas Series with a certain dtype and a certain name. So the Dask version returns a Dask Series with the same dtype and the same name.

To get the actual result you can call .compute().

```
In [29]: %time ddf['name'].value_counts().compute()
CPU times: user 1.82 s, sys: 206 ms, total: 2.02 s
Wall time: 1.71 s
Out[29]:
Laura      230906
Ingrid     230838
Kevin       230698
Dan         230621
Frank       230595
George      230594
Ursula      230592
Tim          230542
Hannah      230530
Michael     230504
Victor      230502
Edith       230349
Oliver      230264
Norbert     230197
Wendy       230038
Jerry        229961
Zelda        229909
Sarah        229826
Quinn        229809
Alice        229802
Patricia    229699
Ray          229603
Xavier      229553
Charlie     229303
Bob          229211
Yvonne      228766
Name: name, dtype: int64
```

At that point, you get back the same thing you'd get with pandas, in this case a concrete pandas Series with the count of each name.

Calling .compute causes the full task graph to be executed. This includes reading the data, selecting the columns, and doing the value_counts. The execution is done *in parallel* where possible, and Dask tries to keep the overall memory footprint small. You can work with datasets that are much larger than memory, as long as each partition (a regular pandas DataFrame) fits in memory.

By default, dask.dataframe operations use a threadpool to do operations in parallel. We can also connect to a

cluster to distribute the work on many machines. In this case we'll connect to a local "cluster" made up of several processes on this single machine.

```
>>> from dask.distributed import Client, LocalCluster
>>> cluster = LocalCluster()
>>> client = Client(cluster)
>>> client
<Client: 'tcp://127.0.0.1:53349' processes=4 threads=8, memory=17.18 GB>
```

Once this `client` is created, all of Dask's computation will take place on the cluster (which is just processes in this case).

Dask implements the most used parts of the pandas API. For example, we can do a familiar groupby aggregation.

```
In [30]: %time ddf.groupby('name')[['x', 'y']].mean().compute().head()
CPU times: user 2.93 s, sys: 2.15 s, total: 5.08 s
Wall time: 3.04 s
Out[30]:
      x          y
name
Alice  0.000086 -0.001170
Bob   -0.000843 -0.000799
Charlie  0.000564 -0.000038
Dan    0.000584  0.000818
Edith -0.000116 -0.000044
```

The grouping and aggregation is done out-of-core and in parallel.

When Dask knows the divisions of a dataset, certain optimizations are possible. When reading parquet datasets written by dask, the divisions will be known automatically. In this case, since we created the parquet files manually, we need to supply the divisions manually.

```
In [31]: N = 12
In [32]: starts = [f'20{i}:>02d)-01-01' for i in range(N)]
In [33]: ends = [f'20{i}:>02d)-12-13' for i in range(N)]
In [34]: divisions = tuple(pd.to_datetime(starts)) + (pd.Timestamp(ends[-1]),)
In [35]: ddf.divisions = divisions
In [36]: ddf
Out[36]:
Dask DataFrame Structure:
      id      name          x          y
npartitions=12
2000-01-01    int64  object  float64  float64
2001-01-01        ...     ...     ...     ...
...
2011-01-01    int64  object  float64  float64
2011-12-13        ...     ...     ...     ...
Dask Name: read-parquet, 12 tasks
```

Now we can do things like fast random access with `.loc`.

```
In [37]: ddf.loc['2002-01-01 12:01':'2002-01-01 12:05'].compute()  
Out[37]:
```

timestamp	id	name	x	y
2002-01-01 12:01:00	983	Laura	0.243985	-0.079392
2002-01-01 12:02:00	1001	Laura	-0.523119	-0.226026
2002-01-01 12:03:00	1059	Oliver	0.612886	0.405680
2002-01-01 12:04:00	993	Kevin	0.451977	0.332947
2002-01-01 12:05:00	1014	Yvonne	-0.948681	0.361748

Dask knows to just look in the 3rd partition for selecting values in 2002. It doesn't need to look at any other data.

Many workflows involve a large amount of data and processing it in a way that reduces the size to something that fits in memory. In this case, we'll resample to daily frequency and take the mean. Once we've taken the mean, we know the results will fit in memory, so we can safely call `compute` without running out of memory. At that point it's just a regular pandas object.

```
In [38]: ddf[['x', 'y']].resample("1D").mean().cumsum().compute().plot()  
Out[38]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d6417f9d0>
```

These Dask examples have all been done using multiple processes on a single machine. Dask can be deployed on a cluster to scale up to even larger datasets.

You see more dask examples at <https://examples.dask.org>. {{ header }}

3.20 Sparse data structures

Pandas provides data structures for efficiently storing sparse data. These are not necessarily sparse in the typical “mostly 0”. Rather, you can view these objects as being “compressed” where any data matching a specific value (NaN / missing value, though any value can be chosen, including 0) is omitted. The compressed values are not actually stored in the array.

```
In [1]: arr = np.random.randn(10)

In [2]: arr[2:-2] = np.nan

In [3]: ts = pd.Series(pd.arrays.SparseArray(arr))

In [4]: ts
Out[4]:
0      1.485629
1      0.328995
2        NaN
3        NaN
4        NaN
5        NaN
6        NaN
7        NaN
8     -0.305795
9      0.163245
dtype: Sparse[float64, nan]
```

Notice the dtype, Sparse[float64, nan]. The nan means that elements in the array that are nan aren’t actually stored, only the non-nan elements are. Those non-nan elements have a float64 dtype.

The sparse objects exist for memory efficiency reasons. Suppose you had a large, mostly NA DataFrame:

```
In [5]: df = pd.DataFrame(np.random.randn(10000, 4))

In [6]: df.iloc[:9998] = np.nan

In [7]: sdf = df.astype(pd.SparseDtype("float", np.nan))

In [8]: sdf.head()
Out[8]:
   0   1   2   3
0  NaN  NaN  NaN  NaN
1  NaN  NaN  NaN  NaN
2  NaN  NaN  NaN  NaN
3  NaN  NaN  NaN  NaN
4  NaN  NaN  NaN  NaN

In [9]: sdf.dtypes
Out[9]:
0    Sparse[float64, nan]
1    Sparse[float64, nan]
2    Sparse[float64, nan]
3    Sparse[float64, nan]
dtype: object

In [10]: sdf.sparse.density
Out[10]: 0.0002
```

As you can see, the density (% of values that have not been “compressed”) is extremely low. This sparse object takes up much less memory on disk (pickled) and in the Python interpreter.

```
In [11]: 'dense : {:.0f} bytes'.format(df.memory_usage().sum() / 1e3)
Out[11]: 'dense : 320.13 bytes'

In [12]: 'sparse: {:.0f} bytes'.format(sdf.memory_usage().sum() / 1e3)
Out[12]: 'sparse: 0.22 bytes'
```

Functionally, their behavior should be nearly identical to their dense counterparts.

3.20.1 SparseArray

`arrays.SparseArray` is a `ExtensionArray` for storing an array of sparse values (see `dtypes` for more on extension arrays). It is a 1-dimensional ndarray-like object storing only values distinct from the `fill_value`:

```
In [13]: arr = np.random.randn(10)

In [14]: arr[2:5] = np.nan

In [15]: arr[7:8] = np.nan

In [16]: sparr = pd.arrays.SparseArray(arr)

In [17]: sparr
Out[17]:
[0.6814937596731665, -0.3936934801139613, nan, nan, nan, 1.1656790567319866, -0.
         ↪4627293996578389, nan, -0.12411975873999016, 1.979438803899594]
Fill: nan
IntIndex
Indices: array([0, 1, 5, 6, 8, 9], dtype=int32)
```

A sparse array can be converted to a regular (dense) ndarray with `numpy.asarray()`

```
In [18]: np.asarray(sparr)
Out[18]:
array([ 0.68149376, -0.39369348,           nan,           nan,           nan,
       1.16567906, -0.4627294 ,           nan, -0.12411976,  1.9794388 ])
```

3.20.2 SparseDtype

The `SparseArray.dtype` property stores two pieces of information

1. The `dtype` of the non-sparse values
2. The scalar fill value

```
In [19]: sparr.dtype
Out[19]: Sparse[float64, nan]
```

A `SparseDtype` may be constructed by passing each of these

```
In [20]: pd.SparseDtype(np.dtype('datetime64[ns]'))
Out[20]: Sparse[datetime64[ns], NaT]
```

The default fill value for a given NumPy `dtype` is the “missing” value for that `dtype`, though it may be overridden.

```
In [21]: pd.SparseDtype(np.dtype('datetime64[ns]'),
.....           fill_value=pd.Timestamp('2017-01-01'))
.....
Out[21]: Sparse[datetime64[ns], 2017-01-01 00:00:00]
```

Finally, the string alias 'Sparse[dtype]' may be used to specify a sparse dtype in many places

```
In [22]: pd.array([1, 0, 0, 2], dtype='Sparse[int]')
Out[22]:
[1, 0, 0, 2]
Fill: 0
IntIndex
Indices: array([0, 3], dtype=int32)
```

3.20.3 Sparse accessor

New in version 0.24.0.

Pandas provides a `.sparse` accessor, similar to `.str` for string data, `.cat` for categorical data, and `.dt` for datetime-like data. This namespace provides attributes and methods that are specific to sparse data.

```
In [23]: s = pd.Series([0, 0, 1, 2], dtype="Sparse[int]")
In [24]: s.sparse.density
Out[24]: 0.5
In [25]: s.sparse.fill_value
Out[25]: 0
```

This accessor is available only on data with `SparseDtype`, and on the `Series` class itself for creating a `Series` with sparse data from a `scipy COO` matrix with.

New in version 0.25.0.

A `.sparse` accessor has been added for `DataFrame` as well. See [Sparse accessor](#) for more.

3.20.4 Sparse calculation

You can apply NumPy `ufuncs` to `SparseArray` and get a `SparseArray` as a result.

```
In [26]: arr = pd.arrays.SparseArray([1., np.nan, np.nan, -2., np.nan])
In [27]: np.abs(arr)
Out[27]:
[1.0, nan, nan, 2.0, nan]
Fill: nan
IntIndex
Indices: array([0, 3], dtype=int32)
```

The `ufunc` is also applied to `fill_value`. This is needed to get the correct dense result.

```
In [28]: arr = pd.arrays.SparseArray([1., -1, -1, -2., -1], fill_value=-1)
In [29]: np.abs(arr)
Out[29]:
```

(continues on next page)

(continued from previous page)

```
[1.0, 1, 1, 2.0, 1]
Fill: 1
IntIndex
Indices: array([0, 3], dtype=int32)

In [30]: np.abs(arr).to_dense()
Out[30]: array([1., 1., 1., 2., 1.])
```

3.20.5 Migrating

Note: `SparseSeries` and `SparseDataFrame` were removed in pandas 1.0.0. This migration guide is present to aid in migrating from previous versions.

In older versions of pandas, the `SparseSeries` and `SparseDataFrame` classes (documented below) were the preferred way to work with sparse data. With the advent of extension arrays, these subclasses are no longer needed. Their purpose is better served by using a regular Series or DataFrame with sparse values instead.

Note: There's no performance or memory penalty to using a Series or DataFrame with sparse values, rather than a `SparseSeries` or `SparseDataFrame`.

This section provides some guidance on migrating your code to the new style. As a reminder, you can use the python warnings module to control warnings. But we recommend modifying your code, rather than ignoring the warning.

Construction

From an array-like, use the regular Series or DataFrame constructors with `SparseArray` values.

```
# Previous way
>>> pd.SparseDataFrame({"A": [0, 1]})
```

```
# New way
In [31]: pd.DataFrame({"A": pd.arrays.SparseArray([0, 1])})
Out[31]:
A
0  0
1  1
```

From a SciPy sparse matrix, use `DataFrame.sparse.from_spmatrix()`,

```
# Previous way
>>> from scipy import sparse
>>> mat = sparse.eye(3)
>>> df = pd.SparseDataFrame(mat, columns=['A', 'B', 'C'])
```

```
# New way
In [32]: from scipy import sparse

In [33]: mat = sparse.eye(3)

In [34]: df = pd.DataFrame.sparse.from_spmatrix(mat, columns=['A', 'B', 'C'])
```

(continues on next page)

(continued from previous page)

```
In [35]: df.dtypes
Out[35]:
A    Sparse[float64, 0.0]
B    Sparse[float64, 0.0]
C    Sparse[float64, 0.0]
dtype: object
```

Conversion

From sparse to dense, use the `.sparse` accessors

```
In [36]: df.sparse.to_dense()
Out[36]:
   A    B    C
0  1.0  0.0  0.0
1  0.0  1.0  0.0
2  0.0  0.0  1.0

In [37]: df.sparse.to_coo()
Out[37]:
<3x3 sparse matrix of type '<class 'numpy.float64'>'>
      with 3 stored elements in COOrdinate format>
```

From dense to sparse, use `DataFrame.astype()` with a `SparseDtype`.

```
In [38]: dense = pd.DataFrame({"A": [1, 0, 0, 1]})

In [39]: dtype = pd.SparseDtype(int, fill_value=0)

In [40]: dense.astype(dtype)
Out[40]:
   A
0  1
1  0
2  0
3  1
```

Sparse Properties

Sparse-specific properties, like `density`, are available on the `.sparse` accessor.

```
In [41]: df.sparse.density
Out[41]: 0.3333333333333333
```

General differences

In a `SparseDataFrame`, *all* columns were sparse. A `DataFrame` can have a mixture of sparse and dense columns. As a consequence, assigning new columns to a `DataFrame` with sparse values will not automatically convert the input to be sparse.

```
# Previous Way
>>> df = pd.SparseDataFrame({"A": [0, 1]})
>>> df['B'] = [0, 0] # implicitly becomes Sparse
>>> df['B'].dtype
Sparse[int64, nan]
```

Instead, you'll need to ensure that the values being assigned are sparse

```
In [42]: df = pd.DataFrame({ "A": pd.arrays.SparseArray([0, 1]) })

In [43]: df['B'] = [0, 0] # remains dense

In [44]: df['B'].dtype
Out[44]: dtype('int64')

In [45]: df['B'] = pd.arrays.SparseArray([0, 0])

In [46]: df['B'].dtype
Out[46]: Sparse[int64, 0]
```

The `SparseDataFrame.default_kind` and `SparseDataFrame.default_fill_value` attributes have no replacement.

3.20.6 Interaction with scipy.sparse

Use `DataFrame.sparse.from_spmatrix()` to create a DataFrame with sparse values from a sparse matrix.
New in version 0.25.0.

```
In [47]: from scipy.sparse import csr_matrix

In [48]: arr = np.random.random(size=(1000, 5))

In [49]: arr[arr < .9] = 0

In [50]: sp_arr = csr_matrix(arr)

In [51]: sp_arr
Out[51]:
<1000x5 sparse matrix of type '<class 'numpy.float64'>'>
      with 464 stored elements in Compressed Sparse Row format>

In [52]: sdf = pd.DataFrame.sparse.from_spmatrix(sp_arr)

In [53]: sdf.head()
Out[53]:
   0      1      2      3      4
0  0.0  0.921245  0.0  0.000000  0.000000
1  0.0  0.000000  0.0  0.000000  0.000000
2  0.0  0.000000  0.0  0.000000  0.000000
3  0.0  0.000000  0.0  0.000000  0.000000
4  0.0  0.000000  0.0  0.936826  0.918174

In [54]: sdf.dtypes
Out[54]:
0    Sparse[float64, 0.0]
1    Sparse[float64, 0.0]
2    Sparse[float64, 0.0]
3    Sparse[float64, 0.0]
4    Sparse[float64, 0.0]
dtype: object
```

All sparse formats are supported, but matrices that are not in `COO`rdinate format will be converted, copying data as needed. To convert back to sparse SciPy matrix in COO format, you can use the `DataFrame.sparse.to_coo()` method:

```
In [55]: sdf.sparse.to_coo()
Out[55]:
<1000x5 sparse matrix of type '<class 'numpy.float64'>'
      with 464 stored elements in COOrdinate format>
```

meth:`Series.sparse.to_coo` is implemented for transforming a Series with sparse values indexed by a MultiIndex to a `scipy.sparse.coo_matrix`.

The method requires a MultiIndex with two or more levels.

```
In [56]: s = pd.Series([3.0, np.nan, 1.0, 3.0, np.nan, np.nan])

In [57]: s.index = pd.MultiIndex.from_tuples([(1, 2, 'a', 0),
.....:                               (1, 2, 'a', 1),
.....:                               (1, 1, 'b', 0),
.....:                               (1, 1, 'b', 1),
.....:                               (2, 1, 'b', 0),
.....:                               (2, 1, 'b', 1)],
.....:                               names=['A', 'B', 'C', 'D'])

In [58]: s
Out[58]:
A   B   C   D
1   2   a   0   3.0
          1   NaN
        1   b   0   1.0
          1   3.0
2   1   b   0   NaN
          1   NaN
dtype: float64

In [59]: ss = s.astype('Sparse')

In [60]: ss
Out[60]:
A   B   C   D
1   2   a   0   3.0
          1   NaN
        1   b   0   1.0
          1   3.0
2   1   b   0   NaN
          1   NaN
dtype: Sparse[float64, nan]
```

In the example below, we transform the Series to a sparse representation of a 2-d array by specifying that the first and second MultiIndex levels define labels for the rows and the third and fourth levels define labels for the columns. We also specify that the column and row labels should be sorted in the final sparse representation.

```
In [61]: A, rows, columns = ss.sparse.to_coo(row_levels=['A', 'B'],
.....:                                         column_levels=['C', 'D'],
.....:                                         sort_labels=True)

In [62]: A
Out[62]:
<3x4 sparse matrix of type '<class 'numpy.float64'>'
```

(continues on next page)

(continued from previous page)

```
with 3 stored elements in COOrdinate format>

In [63]: A.todense()
Out[63]:
matrix([[0., 0., 1., 3.],
       [3., 0., 0., 0.],
       [0., 0., 0., 0.]])
```

```
In [64]: rows
Out[64]: [(1, 1), (1, 2), (2, 1)]
```

```
In [65]: columns
Out[65]: [('a', 0), ('a', 1), ('b', 0), ('b', 1)]
```

Specifying different row and column labels (and not sorting them) yields a different sparse matrix:

```
In [66]: A, rows, columns = ss.sparse.to_coo(row_levels=['A', 'B', 'C'],
                                             column_levels=['D'],
                                             sort_labels=False)
....:
....:
....:
```

```
In [67]: A
Out[67]:
<3x2 sparse matrix of type '<class 'numpy.float64'>'>
      with 3 stored elements in COOrdinate format>
```

```
In [68]: A.todense()
Out[68]:
matrix([[3., 0.],
       [1., 3.],
       [0., 0.]])
```

```
In [69]: rows
Out[69]: [(1, 2, 'a'), (1, 1, 'b'), (2, 1, 'b')]
```

```
In [70]: columns
Out[70]: [0, 1]
```

A convenience method Series.sparse.from_coo() is implemented for creating a Series with sparse values from a scipy.sparse.coo_matrix.

```
In [71]: from scipy import sparse
```

```
In [72]: A = sparse.coo_matrix(([3.0, 1.0, 2.0], ([1, 0, 0], [0, 2, 3])), 
                               shape=(3, 4))
....:
....:
```

```
In [73]: A
Out[73]:
<3x4 sparse matrix of type '<class 'numpy.float64'>'>
      with 3 stored elements in COOrdinate format>
```

```
In [74]: A.todense()
Out[74]:
matrix([[0., 0., 1., 2.],
       [3., 0., 0., 0.],
       [0., 0., 0., 0.]])
```

The default behaviour (with `dense_index=False`) simply returns a `Series` containing only the non-null entries.

```
In [75]: ss = pd.Series.sparse.from_coo(A)

In [76]: ss
Out[76]:
0    2    1.0
      3    2.0
1    0    3.0
dtype: Sparse[float64, nan]
```

Specifying `dense_index=True` will result in an index that is the Cartesian product of the row and columns coordinates of the matrix. Note that this will consume a significant amount of memory (relative to `dense_index=False`) if the sparse matrix is large (and sparse) enough.

```
In [77]: ss_dense = pd.Series.sparse.from_coo(A, dense_index=True)

In [78]: ss_dense
Out[78]:
0  0    NaN
   1    NaN
   2    1.0
   3    2.0
1  0    3.0
   1    NaN
   2    NaN
   3    NaN
2  0    NaN
   1    NaN
   2    NaN
   3    NaN
dtype: Sparse[float64, nan]
```

{{ header }}

3.21 Frequently Asked Questions (FAQ)

3.21.1 DataFrame memory usage

The memory usage of a `DataFrame` (including the index) is shown when calling the `info()`. A configuration option, `display.memory_usage` (see [the list of options](#)), specifies if the `DataFrame`'s memory usage will be displayed when invoking the `df.info()` method.

For example, the memory usage of the `DataFrame` below is shown when calling `info()`:

```
In [1]: dtypes = ['int64', 'float64', 'datetime64[ns]', 'timedelta64[ns]',
....          'complex128', 'object', 'bool']
.....

In [2]: n = 5000

In [3]: data = {t: np.random.randint(100, size=n).astype(t) for t in dtypes}

In [4]: df = pd.DataFrame(data)
```

(continues on next page)

(continued from previous page)

```
In [5]: df['categorical'] = df['object'].astype('category')

In [6]: df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5000 entries, 0 to 4999
Data columns (total 8 columns):
 #   Column           Non-Null Count  Dtype  
--- 
 0   int64            5000 non-null    int64  
 1   float64          5000 non-null    float64 
 2   datetime64[ns]   5000 non-null    datetime64[ns]
 3   timedelta64[ns] 5000 non-null    timedelta64[ns]
 4   complex128       5000 non-null    complex128
 5   object            5000 non-null    object  
 6   bool              5000 non-null    bool    
 7   categorical       5000 non-null    category
dtypes: bool(1), category(1), complex128(1), datetime64[ns](1), float64(1), int64(1), object(1), timedelta64[ns](1)
memory usage: 289.1+ KB
```

The + symbol indicates that the true memory usage could be higher, because pandas does not count the memory used by values in columns with `dtype=object`.

Passing `memory_usage='deep'` will enable a more accurate memory usage report, accounting for the full usage of the contained objects. This is optional as it can be expensive to do this deeper introspection.

```
In [7]: df.info(memory_usage='deep')
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5000 entries, 0 to 4999
Data columns (total 8 columns):
 #   Column           Non-Null Count  Dtype  
--- 
 0   int64            5000 non-null    int64  
 1   float64          5000 non-null    float64 
 2   datetime64[ns]   5000 non-null    datetime64[ns]
 3   timedelta64[ns] 5000 non-null    timedelta64[ns]
 4   complex128       5000 non-null    complex128
 5   object            5000 non-null    object  
 6   bool              5000 non-null    bool    
 7   categorical       5000 non-null    category
dtypes: bool(1), category(1), complex128(1), datetime64[ns](1), float64(1), int64(1), object(1), timedelta64[ns](1)
memory usage: 425.6 KB
```

By default the `display` option is set to `True` but can be explicitly overridden by passing the `memory_usage` argument when invoking `df.info()`.

The memory usage of each column can be found by calling the `memory_usage()` method. This returns a Series with an index represented by column names and memory usage of each column shown in bytes. For the DataFrame above, the memory usage of each column and the total memory usage can be found with the `memory_usage` method:

```
In [8]: df.memory_usage()
Out[8]:
Index           128
int64          40000
float64        40000
datetime64[ns] 40000
```

(continues on next page)

(continued from previous page)

```
timedelta64[ns]      40000
complex128           80000
object                40000
bool                  5000
categorical          10920
dtype: int64

# total memory usage of dataframe
In [9]: df.memory_usage().sum()
Out[9]: 296048
```

By default the memory usage of the DataFrame's index is shown in the returned Series, the memory usage of the index can be suppressed by passing the `index=False` argument:

```
In [10]: df.memory_usage(index=False)
Out[10]:
int64        40000
float64      40000
datetime64[ns] 40000
timedelta64[ns] 40000
complex128    80000
object        40000
bool          5000
categorical   10920
dtype: int64
```

The memory usage displayed by the `info()` method utilizes the `memory_usage()` method to determine the memory usage of a DataFrame while also formatting the output in human-readable units (base-2 representation; i.e. 1KB = 1024 bytes).

See also [Categorical Memory Usage](#).

3.21.2 Using if/truth statements with pandas

pandas follows the NumPy convention of raising an error when you try to convert something to a `bool`. This happens in an `if`-statement or when using the boolean operations: `and`, `or`, and `not`. It is not clear what the result of the following code should be:

```
>>> if pd.Series([False, True, False]):
...     pass
```

Should it be `True` because it's not zero-length, or `False` because there are `False` values? It is unclear, so instead, pandas raises a `ValueError`:

```
>>> if pd.Series([False, True, False]):
...     print("I was true")
Traceback
...
ValueError: The truth value of an array is ambiguous. Use a.empty, a.any() or a.all().
```

You need to explicitly choose what you want to do with the DataFrame, e.g. use `any()`, `all()` or `empty()`. Alternatively, you might want to compare if the pandas object is `None`:

```
>>> if pd.Series([False, True, False]) is not None:  
...     print("I was not None")  
I was not None
```

Below is how to check if any of the values are True:

```
>>> if pd.Series([False, True, False]).any():  
...     print("I am any")  
I am any
```

To evaluate single-element pandas objects in a boolean context, use the method `bool()`:

```
In [11]: pd.Series([True]).bool()  
Out[11]: True  
  
In [12]: pd.Series([False]).bool()  
Out[12]: False  
  
In [13]: pd.DataFrame([[True]]).bool()  
Out[13]: True  
  
In [14]: pd.DataFrame([[False]]).bool()  
Out[14]: False
```

Bitwise boolean

Bitwise boolean operators like `==` and `!=` return a boolean Series, which is almost always what you want anyways.

```
>>> s = pd.Series(range(5))  
>>> s == 4  
0    False  
1    False  
2    False  
3    False  
4    True  
dtype: bool
```

See [boolean comparisons](#) for more examples.

Using the `in` operator

Using the Python `in` operator on a Series tests for membership in the index, not membership among the values.

```
In [15]: s = pd.Series(range(5), index=list('abcde'))  
  
In [16]: 2 in s  
Out[16]: False  
  
In [17]: 'b' in s  
Out[17]: True
```

If this behavior is surprising, keep in mind that using `in` on a Python dictionary tests keys, not values, and Series are dict-like. To test for membership in the values, use the method `isin()`:

```
In [18]: s.isin([2])
Out[18]:
a    False
b    False
c     True
d    False
e    False
dtype: bool

In [19]: s.isin([2]).any()
Out[19]: True
```

For DataFrames, likewise, `in` applies to the column axis, testing for membership in the list of column names.

3.21.3 NaN, Integer NA values and NA type promotions

Choice of NA representation

For lack of NA (missing) support from the ground up in NumPy and Python in general, we were given the difficult choice between either:

- A *masked array* solution: an array of data and an array of boolean values indicating whether a value is there or is missing.
- Using a special sentinel value, bit pattern, or set of sentinel values to denote NA across the dtypes.

For many reasons we chose the latter. After years of production use it has proven, at least in my opinion, to be the best decision given the state of affairs in NumPy and Python in general. The special value `NaN` (Not-A-Number) is used everywhere as the NA value, and there are API functions `isna` and `notna` which can be used across the dtypes to detect NA values.

However, it comes with it a couple of trade-offs which I most certainly have not ignored.

Support for integer NA

In the absence of high performance NA support being built into NumPy from the ground up, the primary casualty is the ability to represent NAs in integer arrays. For example:

```
In [20]: s = pd.Series([1, 2, 3, 4, 5], index=list('abcde'))

In [21]: s
Out[21]:
a    1
b    2
c    3
d    4
e    5
dtype: int64

In [22]: s.dtype
Out[22]: dtype('int64')

In [23]: s2 = s.reindex(['a', 'b', 'c', 'f', 'u'])

In [24]: s2
```

(continues on next page)

(continued from previous page)

```
Out[24]:  
a    1.0  
b    2.0  
c    3.0  
f    NaN  
u    NaN  
dtype: float64
```

```
In [25]: s2.dtype  
Out[25]: dtype('float64')
```

This trade-off is made largely for memory and performance reasons, and also so that the resulting `Series` continues to be “numeric”.

If you need to represent integers with possibly missing values, use one of the nullable-integer extension dtypes provided by pandas

- `Int8Dtype`
- `Int16Dtype`
- `Int32Dtype`
- `Int64Dtype`

```
In [26]: s_int = pd.Series([1, 2, 3, 4, 5], index=list('abcde'),  
.....:                      dtype=pd.Int64Dtype())  
.....:
```

```
In [27]: s_int  
Out[27]:
```

```
a    1  
b    2  
c    3  
d    4  
e    5  
dtype: Int64
```

```
In [28]: s_int.dtype  
Out[28]: Int64Dtype()
```

```
In [29]: s2_int = s_int.reindex(['a', 'b', 'c', 'f', 'u'])
```

```
In [30]: s2_int
```

```
Out[30]:  
a    1  
b    2  
c    3  
f    <NA>  
u    <NA>  
dtype: Int64
```

```
In [31]: s2_int.dtype  
Out[31]: Int64Dtype()
```

See [Nullable integer data type](#) for more.

NA type promotions

When introducing NAs into an existing `Series` or `DataFrame` via `reindex()` or some other means, boolean and integer types will be promoted to a different dtype in order to store the NAs. The promotions are summarized in this table:

Typeclass	Promotion dtype for storing NAs
<code>floating</code>	no change
<code>object</code>	no change
<code>integer</code>	cast to <code>float64</code>
<code>boolean</code>	cast to <code>object</code>

While this may seem like a heavy trade-off, I have found very few cases where this is an issue in practice i.e. storing values greater than 2^{**53} . Some explanation for the motivation is in the next section.

Why not make NumPy like R?

Many people have suggested that NumPy should simply emulate the NA support present in the more domain-specific statistical programming language [R](#). Part of the reason is the NumPy type hierarchy:

Typeclass	Dtypes
<code>numpy.floating</code>	<code>float16, float32, float64, float128</code>
<code>numpy.integer</code>	<code>int8, int16, int32, int64</code>
<code>numpy.unsignedinteger</code>	<code>uint8, uint16, uint32, uint64</code>
<code>numpy.object_</code>	<code>object_</code>
<code>numpy.bool_</code>	<code>bool_</code>
<code>numpy.character</code>	<code>string_, unicode_</code>

The R language, by contrast, only has a handful of built-in data types: `integer`, `numeric` (floating-point), `character`, and `boolean`. NA types are implemented by reserving special bit patterns for each type to be used as the missing value. While doing this with the full NumPy type hierarchy would be possible, it would be a more substantial trade-off (especially for the 8- and 16-bit data types) and implementation undertaking.

An alternate approach is that of using masked arrays. A masked array is an array of data with an associated boolean `mask` denoting whether each value should be considered NA or not. I am personally not in love with this approach as I feel that overall it places a fairly heavy burden on the user and the library implementer. Additionally, it exacts a fairly high performance cost when working with numerical data compared with the simple approach of using `NaN`. Thus, I have chosen the Pythonic “practicality beats purity” approach and traded integer NA capability for a much simpler approach of using a special value in float and object arrays to denote NA, and promoting integer arrays to floating when NAs must be introduced.

3.21.4 Differences with NumPy

For `Series` and `DataFrame` objects, `var()` normalizes by $N-1$ to produce unbiased estimates of the sample variance, while NumPy’s `var` normalizes by N , which measures the variance of the sample. Note that `cov()` normalizes by $N-1$ in both pandas and NumPy.

3.21.5 Thread-safety

As of pandas 0.11, pandas is not 100% thread safe. The known issues relate to the `copy()` method. If you are doing a lot of copying of `DataFrame` objects shared among threads, we recommend holding locks inside the threads where the data copying occurs.

See [this link](#) for more information.

3.21.6 Byte-Ordering issues

Occasionally you may have to deal with data that were created on a machine with a different byte order than the one on which you are running Python. A common symptom of this issue is an error like::

```
Traceback
...
ValueError: Big-endian buffer not supported on little-endian compiler
```

To deal with this issue you should convert the underlying NumPy array to the native system byte order *before* passing it to `Series` or `DataFrame` constructors using something similar to the following:

```
In [32]: x = np.array(list(range(10)), '>i4')    # big endian
In [33]: newx = x.byteswap().newbyteorder()    # force native byteorder
In [34]: s = pd.Series(newx)
```

See the NumPy documentation on byte order for more details. {{ header }}

3.22 Cookbook

This is a repository for *short and sweet* examples and links for useful pandas recipes. We encourage users to add to this documentation.

Adding interesting links and/or inline examples to this section is a great *First Pull Request*.

Simplified, condensed, new-user friendly, in-line examples have been inserted where possible to augment the StackOverflow and GitHub links. Many of the links contain expanded information, above what the in-line examples offer.

Pandas (`pd`) and Numpy (`np`) are the only two abbreviated imported modules. The rest are kept explicitly imported for newer users.

These examples are written for Python 3. Minor tweaks might be necessary for earlier python versions.

3.22.1 Idioms

These are some neat pandas idioms

if-then/if-then-else on one column, and assignment to another one or more columns:

```
In [1]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
...:                      'BBB': [10, 20, 30, 40],
...:                      'CCC': [100, 50, -30, -50]})
```

(continues on next page)

(continued from previous page)

```
In [2]: df
Out[2]:
   AAA  BBB  CCC
0    4   10  100
1    5   20   50
2    6   30  -30
3    7   40  -50
```

if-then...

An if-then on one column

```
In [3]: df.loc[df.AAA >= 5, 'BBB'] = -1
In [4]: df
Out[4]:
   AAA  BBB  CCC
0    4   10  100
1    5   -1   50
2    6   -1  -30
3    7   -1  -50
```

An if-then with assignment to 2 columns:

```
In [5]: df.loc[df.AAA >= 5, ['BBB', 'CCC']] = 555
In [6]: df
Out[6]:
   AAA  BBB  CCC
0    4   10  100
1    5  555  555
2    6  555  555
3    7  555  555
```

Add another line with different logic, to do the -else

```
In [7]: df.loc[df.AAA < 5, ['BBB', 'CCC']] = 2000
In [8]: df
Out[8]:
   AAA  BBB  CCC
0    4  2000  2000
1    5    555  555
2    6    555  555
3    7    555  555
```

Or use pandas where after you've set up a mask

```
In [9]: df_mask = pd.DataFrame({'AAA': [True] * 4,
...:                           'BBB': [False] * 4,
...:                           'CCC': [True, False] * 2})
...
In [10]: df.where(df_mask, -1000)
Out[10]:
```

(continues on next page)

(continued from previous page)

	AAA	BBB	CCC
0	4	-1000	2000
1	5	-1000	-1000
2	6	-1000	555
3	7	-1000	-1000

if-then-else using numpy's where()

```
In [11]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
....:                      'BBB': [10, 20, 30, 40],
....:                      'CCC': [100, 50, -30, -50]})

In [12]: df
Out[12]:
      AAA    BBB    CCC
0      4     10    100
1      5     20     50
2      6     30    -30
3      7     40    -50

In [13]: df['logic'] = np.where(df['AAA'] > 5, 'high', 'low')

In [14]: df
Out[14]:
      AAA    BBB    CCC  logic
0      4     10    100    low
1      5     20     50    low
2      6     30    -30   high
3      7     40    -50   high
```

Splitting

Split a frame with a boolean criterion

```
In [15]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
....:                      'BBB': [10, 20, 30, 40],
....:                      'CCC': [100, 50, -30, -50]})

In [16]: df
Out[16]:
      AAA    BBB    CCC
0      4     10    100
1      5     20     50
2      6     30    -30
3      7     40    -50

In [17]: df[df.AAA <= 5]
Out[17]:
      AAA    BBB    CCC
0      4     10    100
1      5     20     50

In [18]: df[df.AAA > 5]
```

(continues on next page)

(continued from previous page)

Out [18] :

	AAA	BBB	CCC
2	6	30	-30
3	7	40	-50

Building criteria

Select with multi-column criteria

```
In [19]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
....:                     'BBB': [10, 20, 30, 40],
....:                     'CCC': [100, 50, -30, -50]})
```

```
In [20]: df
```

Out [20] :

	AAA	BBB	CCC
0	4	10	100
1	5	20	50
2	6	30	-30
3	7	40	-50

...and (without assignment returns a Series)

```
In [21]: df.loc[(df['BBB'] < 25) & (df['CCC'] >= -40), 'AAA']
```

Out [21] :

	AAA
0	4
1	5

Name: AAA, dtype: int64

... or (without assignment returns a Series)

```
In [22]: df.loc[(df['BBB'] > 25) | (df['CCC'] >= -40), 'AAA']
```

Out [22] :

	AAA
0	4
1	5
2	6
3	7

Name: AAA, dtype: int64

... or (with assignment modifies the DataFrame.)

```
In [23]: df.loc[(df['BBB'] > 25) | (df['CCC'] >= 75), 'AAA'] = 0.1
```

```
In [24]: df
```

Out [24] :

	AAA	BBB	CCC
0	0.1	10	100
1	5.0	20	50
2	0.1	30	-30
3	0.1	40	-50

Select rows with data closest to certain value using argsort

```
In [25]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
....:                      'BBB': [10, 20, 30, 40],
....:                      'CCC': [100, 50, -30, -50]})

In [26]: df
Out[26]:
   AAA  BBB  CCC
0    4   10  100
1    5   20   50
2    6   30  -30
3    7   40  -50

In [27]: aValue = 43.0

In [28]: df.loc[(df.CCC - aValue).abs().argsort()]
Out[28]:
   AAA  BBB  CCC
1    5   20   50
0    4   10  100
2    6   30  -30
3    7   40  -50
```

Dynamically reduce a list of criteria using a binary operators

```
In [29]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
....:                      'BBB': [10, 20, 30, 40],
....:                      'CCC': [100, 50, -30, -50]})

In [30]: df
Out[30]:
   AAA  BBB  CCC
0    4   10  100
1    5   20   50
2    6   30  -30
3    7   40  -50

In [31]: Crit1 = df.AAA <= 5.5

In [32]: Crit2 = df.BBB == 10.0

In [33]: Crit3 = df.CCC > -40.0
```

One could hard code:

```
In [34]: AllCrit = Crit1 & Crit2 & Crit3
```

... Or it can be done with a list of dynamically built criteria

```
In [35]: import functools

In [36]: CritList = [Crit1, Crit2, Crit3]

In [37]: AllCrit = functools.reduce(lambda x, y: x & y, CritList)

In [38]: df[AllCrit]
```

(continues on next page)

(continued from previous page)

Out [38] :

	AAA	BBB	CCC
0	4	10	100

3.22.2 Selection

DataFrames

The *indexing* docs.

Using both row labels and value conditionals

```
In [39]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
....:                     'BBB': [10, 20, 30, 40],
....:                     'CCC': [100, 50, -30, -50]})

In [40]: df
Out[40]:
      AAA   BBB   CCC
0      4    10   100
1      5    20    50
2      6    30   -30
3      7    40   -50

In [41]: df[(df.AAA <= 6) & (df.index.isin([0, 2, 4]))]
Out[41]:
      AAA   BBB   CCC
0      4    10   100
2      6    30   -30
```

Use loc for label-oriented slicing and iloc positional slicing

```
In [42]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
....:                     'BBB': [10, 20, 30, 40],
....:                     'CCC': [100, 50, -30, -50]},
....:                     index=['foo', 'bar', 'boo', 'kar'])

....:
```

There are 2 explicit slicing methods, with a third general case

1. Positional-oriented (Python slicing style : exclusive of end)
2. Label-oriented (Non-Python slicing style : inclusive of end)
3. General (Either slicing style : depends on if the slice contains labels or positions)

```
In [43]: df.loc['bar':'kar'] # Label
Out[43]:
      AAA   BBB   CCC
bar      5    20    50
boo      6    30   -30
kar      7    40   -50

# Generic
In [44]: df.iloc[0:3]
```

(continues on next page)

(continued from previous page)

```
Out[44]:
      AAA   BBB   CCC
foo    4     10    100
bar    5     20     50
boo    6     30    -30
```

```
In [45]: df.loc['bar':'kar']
```

```
Out[45]:
      AAA   BBB   CCC
bar    5     20     50
boo    6     30    -30
kar    7     40    -50
```

Ambiguity arises when an index consists of integers with a non-zero start or non-unit increment.

```
In [46]: data = {'AAA': [4, 5, 6, 7],
.....:          'BBB': [10, 20, 30, 40],
.....:          'CCC': [100, 50, -30, -50]}

.....:
```

```
In [47]: df2 = pd.DataFrame(data=data, index=[1, 2, 3, 4]) # Note index starts at 1.
```

```
In [48]: df2.iloc[1:3] # Position-oriented
```

```
Out[48]:
      AAA   BBB   CCC
2     5     20     50
3     6     30    -30
```

```
In [49]: df2.loc[1:3] # Label-oriented
```

```
Out[49]:
      AAA   BBB   CCC
1     4     10    100
2     5     20     50
3     6     30    -30
```

Using inverse operator (\sim) to take the complement of a mask

```
In [50]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
.....:                      'BBB': [10, 20, 30, 40],
.....:                      'CCC': [100, 50, -30, -50]})

.....:
```

```
In [51]: df
```

```
Out[51]:
      AAA   BBB   CCC
0     4     10    100
1     5     20     50
2     6     30    -30
3     7     40    -50
```

```
In [52]: df[~((df.AAA <= 6) & (df.index.isin([0, 2, 4])))]
```

```
Out[52]:
      AAA   BBB   CCC
1     5     20     50
3     7     40    -50
```

New columns

Efficiently and dynamically creating new columns using applymap

```
In [53]: df = pd.DataFrame({'AAA': [1, 2, 1, 3],
....:                      'BBB': [1, 1, 2, 2],
....:                      'CCC': [2, 1, 3, 1]})

In [54]: df
Out[54]:
   AAA  BBB  CCC
0     1     1     2
1     2     1     1
2     1     2     3
3     3     2     1

In [55]: source_cols = df.columns    # Or some subset would work too

In [56]: new_cols = [str(x) + "_cat" for x in source_cols]

In [57]: categories = {1: 'Alpha', 2: 'Beta', 3: 'Charlie'}

In [58]: df[new_cols] = df[source_cols].applymap(categories.get)

In [59]: df
Out[59]:
   AAA  BBB  CCC  AAA_cat  BBB_cat  CCC_cat
0     1     1     2      Alpha     Alpha     Beta
1     2     1     1      Beta      Alpha     Alpha
2     1     2     3      Alpha     Beta     Charlie
3     3     2     1     Charlie     Beta     Alpha
```

Keep other columns when using min() with groupby

```
In [60]: df = pd.DataFrame({'AAA': [1, 1, 1, 2, 2, 2, 3, 3],
....:                      'BBB': [2, 1, 3, 4, 5, 1, 2, 3]})

In [61]: df
Out[61]:
   AAA  BBB
0     1     2
1     1     1
2     1     3
3     2     4
4     2     5
5     2     1
6     3     2
7     3     3
```

Method 1 : idxmin() to get the index of the minimums

```
In [62]: df.loc[df.groupby("AAA") ["BBB"].idxmin()]
Out[62]:
   AAA  BBB
1     1     1
5     2     1
```

(continues on next page)

(continued from previous page)

6	3	2
---	---	---

Method 2 : sort then take first of each

```
In [63]: df.sort_values(by="BBB").groupby("AAA", as_index=False).first()
Out[63]:
   AAA    BBB
0     1      1
1     2      1
2     3      2
```

Notice the same results, with the exception of the index.

3.22.3 MultiIndexing

The [multindexing](#) docs.

Creating a MultiIndex from a labeled frame

```
In [64]: df = pd.DataFrame({'row': [0, 1, 2],
....:                   'One_X': [1.1, 1.1, 1.1],
....:                   'One_Y': [1.2, 1.2, 1.2],
....:                   'Two_X': [1.11, 1.11, 1.11],
....:                   'Two_Y': [1.22, 1.22, 1.22]})

In [65]: df
Out[65]:
   row  One_X  One_Y  Two_X  Two_Y
0     0     1.1    1.2    1.11   1.22
1     1     1.1    1.2    1.11   1.22
2     2     1.1    1.2    1.11   1.22

# As Labelled Index
In [66]: df = df.set_index('row')

In [67]: df
Out[67]:
   One_X  One_Y  Two_X  Two_Y
row
0     1.1    1.2    1.11   1.22
1     1.1    1.2    1.11   1.22
2     1.1    1.2    1.11   1.22

# With Hierarchical Columns
In [68]: df.columns = pd.MultiIndex.from_tuples([tuple(c.split('_'))
....:                                              for c in df.columns])
....:

In [69]: df
Out[69]:
   One          Two
      X      Y      X      Y
row
0     1.1    1.2    1.11   1.22
1     1.1    1.2    1.11   1.22
```

(continues on next page)

(continued from previous page)

```

2    1.1  1.2  1.11  1.22

# Now stack & Reset
In [70]: df = df.stack(0).reset_index(1)

In [71]: df
Out[71]:
   level_1      X      Y
row
0     One  1.10  1.20

```

Arithmetic

Performing arithmetic with a MultiIndex that needs broadcasting

```

In [74]: cols = pd.MultiIndex.from_tuples([(x, y) for x in ['A', 'B', 'C']
                                             for y in ['O', 'I']])
....:
....:

In [75]: df = pd.DataFrame(np.random.randn(2, 6), index=['n', 'm'], columns=cols)

In [76]: df
Out[76]:
          A           B           C
          O           O           O
n -1.158604  0.231216 -1.204649 -1.143851 -1.402844  0.865751
m -0.336873 -0.007031 -2.313494 -0.290680  0.116972 -0.762744

In [77]: df = df.div(df['C'], level=1)

In [78]: df
Out[78]:
          A           B           C
          O           O           O
n  0.825896  0.267070  0.858719 -1.321223  1.0  1.0
m -2.879939  0.009219 -19.778122  0.381098  1.0  1.0

```

Slicing

Slicing a MultiIndex with xs

```
In [79]: coords = [('AA', 'one'), ('AA', 'six'), ('BB', 'one'), ('BB', 'two'),  
.....:             ('BB', 'six')]  
.....:  
  
In [80]: index = pd.MultiIndex.from_tuples(coords)  
  
In [81]: df = pd.DataFrame([11, 22, 33, 44, 55], index, ['MyData'])  
  
In [82]: df  
Out[82]:  
          MyData  
AA one      11  
      six      22  
BB one      33  
      two      44  
      six      55
```

To take the cross section of the 1st level and 1st axis the index:

```
# Note : level and axis are optional, and default to zero  
In [83]: df.xs('BB', level=0, axis=0)  
Out[83]:  
          MyData  
one      33  
two      44  
six      55
```

...and now the 2nd level of the 1st axis.

```
In [84]: df.xs('six', level=1, axis=0)  
Out[84]:  
          MyData  
AA      22  
BB      55
```

Slicing a MultiIndex with xs, method #2

```
In [85]: import itertools  
  
In [86]: index = list(itertools.product(['Ada', 'Quinn', 'Violet'],  
.....:                           ['Comp', 'Math', 'Sci']))  
.....:  
  
In [87]: headr = list(itertools.product(['Exams', 'Labs'], ['I', 'II']))  
  
In [88]: idx = pd.MultiIndex.from_tuples(index, names=['Student', 'Course'])  
  
In [89]: cols = pd.MultiIndex.from_tuples(headr)    # Notice these are un-named  
  
In [90]: data = [[70 + x + y + (x * y) % 3 for x in range(4)] for y in range(9)]  
  
In [91]: df = pd.DataFrame(data, idx, cols)  
  
In [92]: df
```

cumsum reset at NaN values

Replace

Using replace with backrefs

3.22.5 Grouping

The *grouping* docs.

Basic grouping with apply

Unlike agg, apply's callable is passed a sub-DataFrame which gives you access to all the columns

```
In [104]: df = pd.DataFrame({'animal': 'cat dog cat fish dog cat cat'.split(),
.....:                               'size': list('SSMMMLL'),
.....:                               'weight': [8, 10, 11, 1, 20, 12, 12],
.....:                               'adult': [False] * 5 + [True] * 2})
.....:

In [105]: df
Out[105]:
   animal  size  weight  adult
0      cat     S       8  False
1      dog     S      10  False
2      cat     M      11  False
3      fish    M       1  False
4      dog     M      20  False
5      cat     L      12   True
6      cat     L      12   True

# List the size of the animals with the highest weight.
In [106]: df.groupby('animal').apply(lambda subf: subf['size'][subf['weight'].idxmax()])
Out[106]:
animal
cat      L
dog      M
fish     M
dtype: object
```

Using get_group

```
In [107]: gb = df.groupby(['animal'])
```

(continues on next page)

(continued from previous page)

```
In [108]: gb.get_group('cat')
```

```
Out[108]:
```

	animal	size	weight	adult
0	cat	S	8	False
2	cat	M	11	False
5	cat	L	12	True
6	cat	L	12	True

Apply to different items in a group

```
In [109]: def GrowUp(x):
.....:     avg_weight = sum(x[x['size'] == 'S'].weight * 1.5)
.....:     avg_weight += sum(x[x['size'] == 'M'].weight * 1.25)
.....:     avg_weight += sum(x[x['size'] == 'L'].weight)
.....:     avg_weight /= len(x)
.....:     return pd.Series(['L', avg_weight, True],
.....:                     index=['size', 'weight', 'adult'])
.....:
```

```
In [110]: expected_df = gb.apply(GrowUp)
```

```
In [111]: expected_df
```

```
Out[111]:
```

	size	weight	adult
animal			
cat	L	12.4375	True
dog	L	20.0000	True
fish	L	1.2500	True

Expanding apply

```
In [112]: S = pd.Series([i / 100.0 for i in range(1, 11)])
```

```
In [113]: def cum_ret(x, y):

.....:     df['stratifying_var'],
.....:     4,
.....:     labels=['0-25%', '25-50%', '50-75%', '75-100%'])
.....:

In [188]: df.boxplot(column='price', by='quartiles')
Out[188]: <matplotlib.axes._subplots.AxesSubplot at 0x7f6d753a3e50>
```

3.22.9 Data In/Out

Performance comparison of SQL vs HDF5

CSV

The [CSV](#) docs

`read_csv` in action

appending to a csv

Reading a csv chunk-by-chunk

Reading only certain rows of a csv chunk-by-chunk

Reading the first few lines of a frame

Reading a file that is compressed but not by gzip/bz2 (the native compressed formats which `read_csv` understands). This example shows a WinZipped file, but is a general application of opening the file within a context manager and using that handle to read. [See here](#)

Inferring dtypes from a file

Dealing with bad lines

Dealing with bad lines II

Reading CSV with Unix timestamps and converting to local timezone

Write a multi-row index CSV without writing duplicates

Reading multiple files to create a single DataFrame

The best way to combine multiple files into a single DataFrame is to read the individual frames one by one, put all of the individual frames into a list, and then combine the frames in the list using `pd.concat()`:

```
In [189]: for i in range(3):
....:     data = pd.DataFrame(np.random.randn(10, 4))
....:     data.to_csv('file_{}.csv'.format(i))
....:

In [190]: files = ['file_0.csv', 'file_1.csv', 'file_2.csv']

In [191]: result = pd.concat([pd.read_csv(f) for f in files], ignore_index=True)
```

You can use the same approach to read all files matching a pattern. Here is an example using `glob`:

```
In [192]: import glob

In [193]: import os

In [194]: files = glob.glob('file_*.csv')

In [195]: result = pd.concat([pd.read_csv(f) for f in files], ignore_index=True)
```

Finally, this strategy will work with the other `pd.read_*`(...) functions described in the [io docs](#).

Parsing date components in multi-columns

Parsing date components in multi-columns is faster with a format

```
In [196]: i = pd.date_range('20000101', periods=10000)

In [197]: df = pd.DataFrame({'year': i.year, 'month': i.month, 'day': i.day})

In [198]: df.head()
Out[198]:
   year  month  day
0    2000      1    1
1    2000      1    2
2    2000      1    3
3    2000      1    4
4    2000      1    5

In [199]: %timeit pd.to_datetime(df.year * 10000 + df.month * 100 + df.day, format='%Y
↪%m%d')
....: ds = df.apply(lambda x: "%04d%02d%02d" % (x['year'],
....:                                              x['month'],
....:                                              x['day']), axis=1)
....: ds.head()
....: %timeit pd.to_datetime(ds)
....:
```

Storing Attributes to a group node

```
In [206]: df = pd.DataFrame(np.random.randn(8, 3))

In [207]: store = pd.HDFStore('test.h5')

In [208]: store.put('df', df)

# you can store an arbitrary Python object via pickle
In [209]: store.get_storer('df').attrs.my_attribute = {'A': 10}

In [210]: store.get_storer('df').attrs.my_attribute
Out[210]: {'A': 10}
```

Binary files

pandas readily accepts NumPy record arrays, if you need to read in a binary file consisting of an array of C structs. For example, given this C program in a file called `main.c` compiled with `gcc main.c -std=gnu99` on a 64-bit machine,

```
#include <stdio.h>
#include <stdint.h>

typedef struct _Data
{
    int32_t count;
    double avg;
    float scale;
} Data;

int main(int argc, const char *argv[])
{
    size_t n = 10;
    Data d[n];

    for (int i = 0; i < n; ++i)
    {
        d[i].count = i;
        d[i].avg = i + 1.0;
        d[i].scale = (float) i + 2.0f;
    }
}
```

(continues on next page)

(continued from previous page)

```

FILE *file = fopen("binary.dat", "wb");
fwrite(&d, sizeof(Data), n, file);
fclose(file);

return 0;
}

```

the following Python code will read the binary file 'binary.dat' into a pandas DataFrame, where each element of the struct corresponds to a column in the frame:

```

names = 'count', 'avg', 'scale'

# note that the offsets are larger than the size of the type because of
# struct padding
offsets = 0, 8, 16
formats = 'i4', 'f8', 'f4'
dt = np.dtype({'names': names, 'offsets': offsets, 'formats': formats},
              align=True)
df = pd.DataFrame(np.fromfile('binary.dat', dt))

```

Note: The offsets of the structure elements may be different depending on the architecture of the machine on which the file was created. Using a raw binary file format like this for general data storage is not recommended, as it is not cross platform. We recommend either HDF5 or parquet, both of which are supported by pandas' IO facilities.

3.22.10 Computation

Numerical integration (sample-based) of a time series

Correlation

Often it's useful to obtain the lower (or upper) triangular form of a correlation matrix calculated from DataFrame.corr(). This can be achieved by passing a boolean mask to where as follows:

```

In [211]: df = pd.DataFrame(np.random.random(size=(100, 5)))

In [212]: corr_mat = df.corr()

In [213]: mask = np.tril(np.ones_like(corr_mat, dtype=np.bool), k=-1)

In [214]: corr_mat.where(mask)
Out[214]:

```

	0	1	2	3	4
0	NaN	NaN	NaN	NaN	NaN
1	0.144755	NaN	NaN	NaN	NaN
2	-0.052054	0.033213	NaN	NaN	NaN
3	-0.030848	-0.010538	0.193206	NaN	NaN
4	-0.014120	0.095587	-0.101069	0.140824	NaN

The *method* argument within DataFrame.corr can accept a callable in addition to the named correlation types. Here we compute the distance correlation matrix for a DataFrame object.

```
In [215]: def distcorr(x, y):
.....:     n = len(x)
.....:     a = np.zeros(shape=(n, n))
.....:     b = np.zeros(shape=(n, n))
.....:     for i in range(n):
.....:         for j in range(i + 1, n):
.....:             a[i, j] = abs(x[i] - x[j])
.....:             b[i, j] = abs(y[i] - y[j])
.....:     a += a.T
.....:     b += b.T
.....:     a_bar = np.vstack([np.nanmean(a, axis=0)] * n)
.....:     b_bar = np.vstack([np.nanmean(b, axis=0)] * n)
.....:     A = a - a_bar - a_bar.T + np.full(shape=(n, n), fill_value=a_bar.mean())
.....:     B = b - b_bar - b_bar.T + np.full(shape=(n, n), fill_value=b_bar.mean())
.....:     cov_ab = np.sqrt(np.nansum(A * B)) / n
.....:     std_a = np.sqrt(np.sqrt(np.nansum(A**2))) / n
.....:     std_b = np.sqrt(np.sqrt(np.nansum(B**2))) / n
.....:     return cov_ab / std_a / std_b
.....:

In [216]: df = pd.DataFrame(np.random.normal(size=(100, 3)))

In [217]: df.corr(method=distcorr)
Out[217]:
   0      1      2
0  1.000000  0.253025  0.207754
1  0.253025  1.000000  0.136275
2  0.207754  0.136275  1.000000
```

3.22.11 Timedeltas

The *Timedeltas* docs.

Using timedeltas

```
In [218]: import datetime

In [219]: s = pd.Series(pd.date_range('2012-1-1', periods=3, freq='D'))

In [220]: s - s.max()
Out[220]:
0   -2 days
1   -1 days
2    0 days
dtype: timedelta64[ns]

In [221]: s.max() - s
Out[221]:
0   2 days
1   1 days
2   0 days
dtype: timedelta64[ns]

In [222]: s - datetime.datetime(2011, 1, 1, 3, 5)
Out[222]:
0   364 days 20:55:00
```

(continues on next page)

(continued from previous page)

```

1    365 days 20:55:00
2    366 days 20:55:00
dtype: timedelta64[ns]

In [223]: s + datetime.timedelta(minutes=5)
Out[223]:
0    2012-01-01 00:05:00
1    2012-01-02 00:05:00
2    2012-01-03 00:05:00
dtype: datetime64[ns]

In [224]: datetime.datetime(2011, 1, 1, 3, 5) - s
Out[224]:
0   -365 days +03:05:00
1   -366 days +03:05:00
2   -367 days +03:05:00
dtype: timedelta64[ns]

In [225]: datetime.timedelta(minutes=5) + s
Out[225]:
0    2012-01-01 00:05:00
1    2012-01-02 00:05:00
2    2012-01-03 00:05:00
dtype: datetime64[ns]

```

Adding and subtracting deltas and dates

```

In [226]: deltas = pd.Series([datetime.timedelta(days=i) for i in range(3)])
In [227]: df = pd.DataFrame({'A': s, 'B': deltas})
In [228]: df
Out[228]:
          A      B
0 2012-01-01 0 days
1 2012-01-02 1 days
2 2012-01-03 2 days

In [229]: df['New Dates'] = df['A'] + df['B']

In [230]: df['Delta'] = df['A'] - df['New Dates']

In [231]: df
Out[231]:
          A      B  New Dates  Delta
0 2012-01-01 0 days 2012-01-01 0 days
1 2012-01-02 1 days 2012-01-03 -1 days
2 2012-01-03 2 days 2012-01-05 -2 days

In [232]: df.dtypes
Out[232]:
A            datetime64[ns]
B            timedelta64[ns]
New Dates    datetime64[ns]
Delta        timedelta64[ns]
dtype: object

```

Another example

Values can be set to NaT using np.nan, similar to datetime

```
In [233]: y = s - s.shift()
```

```
In [234]: y
```

```
Out[234]:
```

```
0      NaT  
1    1 days  
2    1 days  
dtype: timedelta64[ns]
```

```
In [235]: y[1] = np.nan
```

```
In [236]: y
```

```
Out[236]:
```

```
0      NaT  
1      NaT  
2    1 days  
dtype: timedelta64[ns]
```

3.22.12 Aliasing axis names

To globally provide aliases for axis names, one can define these 2 functions:

```
In [237]: def set_axis_alias(cls, axis, alias):  
.....:     if axis not in cls._AXIS_NUMBERS:  
.....:         raise Exception("invalid axis [%s] for alias [%s]" % (axis, alias))  
.....:     cls._AXIS_ALIASES[alias] = axis  
.....:
```

```
In [238]: def clear_axis_alias(cls, axis, alias):  
.....:     if axis not in cls._AXIS_NUMBERS:  
.....:         raise Exception("invalid axis [%s] for alias [%s]" % (axis, alias))  
.....:     cls._AXIS_ALIASES.pop(alias, None)  
.....:
```

```
In [239]: set_axis_alias(pd.DataFrame, 'columns', 'myaxis2')
```

```
In [240]: df2 = pd.DataFrame(np.random.randn(3, 2), columns=['c1', 'c2'],  
.....:                         index=['i1', 'i2', 'i3'])  
.....:
```

```
In [241]: df2.sum(axis='myaxis2')
```

```
Out[241]:
```

```
i1   -0.077211  
i2    0.959708  
i3   -0.072593  
dtype: float64
```

```
In [242]: clear_axis_alias(pd.DataFrame, 'columns', 'myaxis2')
```

3.22.13 Creating example data

To create a dataframe from every combination of some given values, like R's `expand.grid()` function, we can create a dict where the keys are column names and the values are lists of the data values:

```
In [243]: def expand_grid(data_dict):
.....:     rows = itertools.product(*data_dict.values())
.....:     return pd.DataFrame.from_records(rows, columns=data_dict.keys())
.....:

In [244]: df = expand_grid({'height': [60, 70],
.....:                         'weight': [100, 140, 180],
.....:                         'sex': ['Male', 'Female']})
.....:

In [245]: df
Out[245]:
   height  weight      sex
0       60     100    Male
1       60     100  Female
2       60     140    Male
3       60     140  Female
4       60     180    Male
5       60     180  Female
6       70     100    Male
7       70     100  Female
8       70     140    Male
9       70     140  Female
10      70     180    Male
11      70     180  Female
```

{{ header }}

API REFERENCE

This page gives an overview of all public pandas objects, functions and methods. All classes and functions exposed in `pandas.*` namespace are public.

Some subpackages are public which include `pandas.errors`, `pandas.plotting`, and `pandas.testing`. Public functions in `pandas.io` and `pandas.tseries` submodules are mentioned in the documentation. `pandas.api.types` subpackage holds some public functions related to data types in pandas.

Warning: The `pandas.core`, `pandas.compat`, and `pandas.util` top-level modules are PRIVATE. Stable functionality in such modules is not guaranteed.

{{ header }}

4.1 Input/output

4.1.1 Pickling

`read_pickle(filepath_or_buffer, ...)` Load pickled pandas object (or any object) from file.

`pandas.read_pickle`

`pandas.read_pickle(filepath_or_buffer: Union[str, pathlib.Path, IO[~AnyStr]], compression: Union[str, NoneType] = 'infer')`
Load pickled pandas object (or any object) from file.

Warning: Loading pickled data received from untrusted sources can be unsafe. See [here](#).

Parameters

filepath_or_buffer [str, path object or file-like object] File path, URL, or buffer where the pickled object will be loaded from.

Changed in version 1.0.0: Accept URL. URL is not limited to S3 and GCS.

compression [{‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}, default ‘infer’] If ‘infer’ and ‘path_or_url’ is path-like, then detect compression from the following extensions: ‘.gz’,

‘.bz2’, ‘.zip’, or ‘.xz’ (otherwise no compression) If ‘infer’ and ‘path_or_url’ is not path-like, then use None (= no decompression).

Returns

unpickled [same type as object stored in file]

See also:

[`DataFrame.to_pickle`](#) Pickle (serialize) DataFrame object to file.

[`Series.to_pickle`](#) Pickle (serialize) Series object to file.

[`read_hdf`](#) Read HDF5 file into a DataFrame.

[`read_sql`](#) Read SQL query or database table into a DataFrame.

[`read_parquet`](#) Load a parquet object, returning a DataFrame.

Notes

`read_pickle` is only guaranteed to be backwards compatible to pandas 0.20.3.

Examples

```
>>> original_df = pd.DataFrame({ "foo": range(5), "bar": range(5, 10) })
>>> original_df
   foo    bar
0     0     5
1     1     6
2     2     7
3     3     8
4     4     9
>>> pd.to_pickle(original_df, "./dummy.pkl")
```

```
>>> unpickled_df = pd.read_pickle("./dummy.pkl")
>>> unpickled_df
   foo    bar
0     0     5
1     1     6
2     2     7
3     3     8
4     4     9
```

```
>>> import os
>>> os.remove("./dummy.pkl")
```

4.1.2 Flat file

<code>read_table(filepath_or_buffer, pathlib.Path, ...)</code>	Read general delimited file into DataFrame.
<code>read_csv(filepath_or_buffer, pathlib.Path, ...)</code>	Read a comma-separated values (csv) file into DataFrame.
<code>read_fwf(filepath_or_buffer, pathlib.Path, ...)</code>	Read a table of fixed-width formatted lines into DataFrame.

pandas.read_table

```
pandas.read_table(filepath_or_buffer: Union[str, pathlib.Path, IO[~AnyStr]], sep='t', delimiter=None, header='infer', names=None, index_col=None, usecols=None, squeeze=False, prefix=None, mangle_dupe_cols=True, dtype=None, engine=None, converters=None, true_values=None, false_values=None, skipinitialspace=False, skiprows=None, skipfooter=0, nrows=None, na_values=None, keep_default_na=True, na_filter=True, verbose=False, skip_blank_lines=True, parse_dates=False, infer_datetime_format=False, keep_date_col=False, date_parser=None, dayfirst=False, cache_dates=True, iterator=False, chunksize=None, compression='infer', thousands=None, decimal: str = ',', lineterminator=None, quotechar='', quoting=0, doublequote=True, escapechar=None, comment=None, encoding=None, dialect=None, error_bad_lines=True, warn_bad_lines=True, delim_whitespace=False, low_memory=True, memory_map=False, float_precision=None)
```

Read general delimited file into DataFrame.

Also supports optionally iterating or breaking of the file into chunks.

Additional help can be found in the online docs for [IO Tools](#).

Parameters

filepath_or_buffer [str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file://localhost/path/to/table.csv`.

If you want to pass in a path object, pandas accepts any `os.PathLike`.

By file-like object, we refer to objects with a `read()` method, such as a file handler (e.g. via builtin `open` function) or `StringIO`.

sep [str, default ‘t’ (tab-stop)] Delimiter to use. If sep is None, the C engine cannot automatically detect the separator, but the Python parsing engine can, meaning the latter will be used and automatically detect the separator by Python’s builtin sniffer tool, `csv.Sniffer`. In addition, separators longer than 1 character and different from ‘\s+’ will be interpreted as regular expressions and will also force the use of the Python parsing engine. Note that regex delimiters are prone to ignoring quoted data. Regex example: ‘\r\t’.

delimiter [str, default None] Alias for sep.

header [int, list of int, default ‘infer’] Row number(s) to use as the column names, and the start of the data. Default behavior is to infer the column names: if no names are passed the behavior is identical to `header=0` and column names are inferred from the first line of the file, if column names are passed explicitly then the behavior is identical to `header=None`. Explicitly pass `header=0` to be able to replace existing names. The header can be a list of integers that specify row locations for a multi-index on the columns e.g. [0,1,3]. Intervening rows that are not specified will be skipped (e.g. 2 in this example is skipped). Note that this

parameter ignores commented lines and empty lines if `skip_blank_lines=True`, so `header=0` denotes the first line of data rather than the first line of the file.

names [array-like, optional] List of column names to use. If the file contains a header row, then you should explicitly pass `header=0` to override the column names. Duplicates in this list are not allowed.

index_col [int, str, sequence of int / str, or False, default None] Column(s) to use as the row labels of the `DataFrame`, either given as string name or column index. If a sequence of int / str is given, a `MultiIndex` is used.

Note: `index_col=False` can be used to force pandas to *not* use the first column as the index, e.g. when you have a malformed file with delimiters at the end of each line.

usecols [list-like or callable, optional] Return a subset of the columns. If list-like, all elements must either be positional (i.e. integer indices into the document columns) or strings that correspond to column names provided either by the user in `names` or inferred from the document header row(s). For example, a valid list-like `usecols` parameter would be `[0, 1, 2]` or `['foo', 'bar', 'baz']`. Element order is ignored, so `usecols=[0, 1]` is the same as `[1, 0]`. To instantiate a `DataFrame` from data with element order preserved use `pd.read_csv(data, usecols=['foo', 'bar'])[['foo', 'bar']]` for columns in `['foo', 'bar']` order or `pd.read_csv(data, usecols=['foo', 'bar'])[['bar', 'foo']]` for `['bar', 'foo']` order.

If callable, the callable function will be evaluated against the column names, returning names where the callable function evaluates to True. An example of a valid callable argument would be `lambda x: x.upper()` in `['AAA', 'BBB', 'DDD']`. Using this parameter results in much faster parsing time and lower memory usage.

squeeze [bool, default False] If the parsed data only contains one column then return a Series.

prefix [str, optional] Prefix to add to column numbers when no header, e.g. ‘X’ for X0, X1, ...

mangle_dupe_cols [bool, default True] Duplicate columns will be specified as ‘X’, ‘X.1’, ... ‘X.N’, rather than ‘X’...‘X’. Passing in False will cause data to be overwritten if there are duplicate names in the columns.

dtype [Type name or dict of column -> type, optional] Data type for data or columns. E.g. `{'a': np.float64, 'b': np.int32, 'c': 'Int64'}` Use `str` or `object` together with suitable `na_values` settings to preserve and not interpret `dtype`. If converters are specified, they will be applied INSTEAD of `dtype` conversion.

engine [{‘c’, ‘python’}], optional] Parser engine to use. The C engine is faster while the python engine is currently more feature-complete.

converters [dict, optional] Dict of functions for converting values in certain columns. Keys can either be integers or column labels.

true_values [list, optional] Values to consider as True.

false_values [list, optional] Values to consider as False.

skipinitialspace [bool, default False] Skip spaces after delimiter.

skiprows [list-like, int or callable, optional] Line numbers to skip (0-indexed) or number of lines to skip (int) at the start of the file.

If callable, the callable function will be evaluated against the row indices, returning True if the row should be skipped and False otherwise. An example of a valid callable argument would be `lambda x: x in [0, 2]`.

skipfooter [int, default 0] Number of lines at bottom of file to skip (Unsupported with engine='c').

nrows [int, optional] Number of rows of file to read. Useful for reading pieces of large files.

na_values [scalar, str, list-like, or dict, optional] Additional strings to recognize as NA/NaN. If dict passed, specific per-column NA values. By default the following values are interpreted as NaN: '', '#N/A', '#N/A N/A', '#NA', '-1.#IND', '-1.#QNAN', '-NaN', '-nan', '1.#IND', '1.#QNAN', '<NA>', 'N/A', 'NA', 'NULL', 'NaN', 'n/a', 'nan', 'null'.

keep_default_na [bool, default True] Whether or not to include the default NaN values when parsing the data. Depending on whether *na_values* is passed in, the behavior is as follows:

- If *keep_default_na* is True, and *na_values* are specified, *na_values* is appended to the default NaN values used for parsing.
- If *keep_default_na* is True, and *na_values* are not specified, only the default NaN values are used for parsing.
- If *keep_default_na* is False, and *na_values* are specified, only the NaN values specified *na_values* are used for parsing.
- If *keep_default_na* is False, and *na_values* are not specified, no strings will be parsed as NaN.

Note that if *na_filter* is passed in as False, the *keep_default_na* and *na_values* parameters will be ignored.

na_filter [bool, default True] Detect missing value markers (empty strings and the value of *na_values*). In data without any NAs, passing *na_filter*=False can improve the performance of reading a large file.

verbose [bool, default False] Indicate number of NA values placed in non-numeric columns.

skip_blank_lines [bool, default True] If True, skip over blank lines rather than interpreting as NaN values.

parse_dates [bool or list of int or names or list of lists or dict, default False] The behavior is as follows:

- boolean. If True -> try parsing the index.
- list of int or names. e.g. If [1, 2, 3] -> try parsing columns 1, 2, 3 each as a separate date column.
- list of lists. e.g. If [[1, 3]] -> combine columns 1 and 3 and parse as a single date column.
- dict, e.g. {‘foo’ : [1, 3]} -> parse columns 1, 3 as date and call result ‘foo’

If a column or index cannot be represented as an array of datetimes, say because of an unparseable value or a mixture of timezones, the column or index will be returned unaltered as an object data type. For non-standard datetime parsing, use `pd.to_datetime` after `pd.read_csv`. To parse an index or column with a mixture of timezones, specify `date_parser` to be a partially-applied `pandas.to_datetime()` with `utc=True`. See [Parsing a CSV with mixed timezones](#) for more.

Note: A fast-path exists for iso8601-formatted dates.

infer_datetime_format [bool, default False] If True and *parse_dates* is enabled, pandas will attempt to infer the format of the datetime strings in the columns, and if it can be inferred, switch to a faster method of parsing them. In some cases this can increase the parsing speed by 5-10x.

keep_date_col [bool, default False] If True and *parse_dates* specifies combining multiple columns then keep the original columns.

date_parser [function, optional] Function to use for converting a sequence of string columns to an array of datetime instances. The default uses `dateutil.parser.parser` to do the conversion. Pandas will try to call `date_parser` in three different ways, advancing to the next if an exception occurs: 1) Pass one or more arrays (as defined by *parse_dates*) as arguments; 2) concatenate (row-wise) the string values from the columns defined by *parse_dates* into a single array and pass that; and 3) call `date_parser` once for each row using one or more strings (corresponding to the columns defined by *parse_dates*) as arguments.

dayfirst [bool, default False] DD/MM format dates, international and European format.

cache_dates [bool, default True] If True, use a cache of unique, converted dates to apply the datetime conversion. May produce significant speed-up when parsing duplicate date strings, especially ones with timezone offsets.

New in version 0.25.0.

iterator [bool, default False] Return `TextFileReader` object for iteration or getting chunks with `get_chunk()`.

chunksize [int, optional] Return `TextFileReader` object for iteration. See the [IO Tools docs](#) for more information on `iterator` and `chunksize`.

compression [{‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}, default ‘infer’] For on-the-fly decompression of on-disk data. If ‘infer’ and *filepath_or_buffer* is path-like, then detect compression from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’, or ‘.xz’ (otherwise no decompression). If using ‘zip’, the ZIP file must contain only one data file to be read in. Set to None for no decompression.

thousands [str, optional] Thousands separator.

decimal [str, default ‘.’] Character to recognize as decimal point (e.g. use ‘,’ for European data).

lineterminator [str (length 1), optional] Character to break file into lines. Only valid with C parser.

quotechar [str (length 1), optional] The character used to denote the start and end of a quoted item. Quoted items can include the delimiter and it will be ignored.

quoting [int or `csv.QUOTE_*` instance, default 0] Control field quoting behavior per `csv.QUOTE_*` constants. Use one of QUOTE_MINIMAL (0), QUOTE_ALL (1), QUOTE_NONNUMERIC (2) or QUOTE_NONE (3).

doublequote [bool, default True] When quotechar is specified and quoting is not QUOTE_NONE, indicate whether or not to interpret two consecutive quotechar elements INSIDE a field as a single quotechar element.

escapechar [str (length 1), optional] One-character string used to escape other characters.

comment [str, optional] Indicates remainder of line should not be parsed. If found at the beginning of a line, the line will be ignored altogether. This parameter must be a single character. Like empty lines (as long as *skip_blank_lines=True*), fully commented lines are ignored by the parameter *header* but not by *skiprows*. For example, if `comment='#'`, parsing `#empty\na,b,c\n1,2,3` with `header=0` will result in ‘a,b,c’ being treated as the header.

encoding [str, optional] Encoding to use for UTF when reading/writing (ex. ‘utf-8’). [List of Python standard encodings](#).

dialect [str or csv.Dialect, optional] If provided, this parameter will override values (default or not) for the following parameters: *delimiter*, *doublequote*, *escapechar*, *skipinitialspace*, *quotechar*, and *quoting*. If it is necessary to override values, a ParserWarning will be issued. See csv.Dialect documentation for more details.

error_bad_lines [bool, default True] Lines with too many fields (e.g. a csv line with too many commas) will by default cause an exception to be raised, and no DataFrame will be returned. If False, then these “bad lines” will be dropped from the DataFrame that is returned.

warn_bad_lines [bool, default True] If error_bad_lines is False, and warn_bad_lines is True, a warning for each “bad line” will be output.

delim_whitespace [bool, default False] Specifies whether or not whitespace (e.g. ' ' or '\t') will be used as the sep. Equivalent to setting *sep=' \s+'*. If this option is set to True, nothing should be passed in for the *delimiter* parameter.

low_memory [bool, default True] Internally process the file in chunks, resulting in lower memory use while parsing, but possibly mixed type inference. To ensure no mixed types either set False, or specify the type with the *dtype* parameter. Note that the entire file is read into a single DataFrame regardless, use the *chunksize* or *iterator* parameter to return the data in chunks. (Only valid with C parser).

memory_map [bool, default False] If a filepath is provided for *filepath_or_buffer*, map the file object directly onto memory and access the data directly from there. Using this option can improve performance because there is no longer any I/O overhead.

float_precision [str, optional] Specifies which converter the C engine should use for floating-point values. The options are *None* for the ordinary converter, *high* for the high-precision converter, and *round_trip* for the round-trip converter.

Returns

DataFrame or TextParser A comma-separated values (csv) file is returned as two-dimensional data structure with labeled axes.

See also:

[to_csv](#) Write DataFrame to a comma-separated values (csv) file.

[read_csv](#) Read a comma-separated values (csv) file into DataFrame.

[read_fwf](#) Read a table of fixed-width formatted lines into DataFrame.

Examples

```
>>> pd.read_table('data.csv')
```

`pandas.read_csv`

```
pandas.read_csv(filepath_or_buffer: Union[str, pathlib.Path, IO[~AnyStr]], sep=',', delimiter=None,
                 header='infer', names=None, index_col=None, usecols=None, squeeze=False,
                 prefix=None, mangle_dupe_cols=True, dtype=None, engine=None, converters=None,
                 true_values=None, false_values=None, skipinitialspace=False,
                 skiprows=None, skipfooter=0, nrows=None, na_values=None, keep_default_na=True,
                 na_filter=True, verbose=False, skip_blank_lines=True, parse_dates=False,
                 infer_datetime_format=False, keep_date_col=False, date_parser=None, dayfirst=False,
                 cache_dates=True, iterator=False, chunksize=None, compression='infer',
                 thousands=None, decimal: str = ',', lineterminator=None, quotechar='',
                 quoting=0, doublequote=True, escapechar=None, comment=None, encoding=None,
                 dialect=None, error_bad_lines=True, warn_bad_lines=True, delim_whitespace=False,
                 low_memory=True, memory_map=False, float_precision=None)
```

Read a comma-separated values (csv) file into DataFrame.

Also supports optionally iterating or breaking of the file into chunks.

Additional help can be found in the online docs for [IO Tools](#).

Parameters

filepath_or_buffer [str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file://localhost/path/to/table.csv`.

If you want to pass in a path object, pandas accepts any `os.PathLike`.

By file-like object, we refer to objects with a `read()` method, such as a file handler (e.g. via builtin `open` function) or `StringIO`.

sep [str, default ','] Delimiter to use. If `sep` is `None`, the C engine cannot automatically detect the separator, but the Python parsing engine can, meaning the latter will be used and automatically detect the separator by Python's builtin sniffer tool, `csv.Sniffer`. In addition, separators longer than 1 character and different from `'\s+'` will be interpreted as regular expressions and will also force the use of the Python parsing engine. Note that regex delimiters are prone to ignoring quoted data. Regex example: `'\r\t'`.

delimiter [str, default `None`] Alias for `sep`.

header [int, list of int, default 'infer'] Row number(s) to use as the column names, and the start of the data. Default behavior is to infer the column names: if no names are passed the behavior is identical to `header=0` and column names are inferred from the first line of the file, if column names are passed explicitly then the behavior is identical to `header=None`. Explicitly pass `header=0` to be able to replace existing names. The header can be a list of integers that specify row locations for a multi-index on the columns e.g. `[0,1,3]`. Intervening rows that are not specified will be skipped (e.g. 2 in this example is skipped). Note that this parameter ignores commented lines and empty lines if `skip_blank_lines=True`, so `header=0` denotes the first line of data rather than the first line of the file.

names [array-like, optional] List of column names to use. If the file contains a header row, then you should explicitly pass `header=0` to override the column names. Duplicates in this list are not allowed.

index_col [int, str, sequence of int / str, or False, default `None`] Column(s) to use as the row labels of the `DataFrame`, either given as string name or column index. If a sequence of int / str is given, a `MultiIndex` is used.

Note: `index_col=False` can be used to force pandas to *not* use the first column as the index, e.g. when you have a malformed file with delimiters at the end of each line.

usecols [list-like or callable, optional] Return a subset of the columns. If list-like, all elements must either be positional (i.e. integer indices into the document columns) or strings that correspond to column names provided either by the user in *names* or inferred from the document header row(s). For example, a valid list-like *usecols* parameter would be [0, 1, 2] or ['foo', 'bar', 'baz']. Element order is ignored, so *usecols*=[0, 1] is the same as [1, 0]. To instantiate a DataFrame from data with element order preserved use `pd.read_csv(data, usecols=['foo', 'bar'])`[[['foo', 'bar']] for columns in ['foo', 'bar']] order or `pd.read_csv(data, usecols=['foo', 'bar'])`[[['bar', 'foo']]] for ['bar', 'foo'] order.

If callable, the callable function will be evaluated against the column names, returning names where the callable function evaluates to True. An example of a valid callable argument would be `lambda x: x.upper()` in ['AAA', 'BBB', 'DDD']. Using this parameter results in much faster parsing time and lower memory usage.

squeeze [bool, default False] If the parsed data only contains one column then return a Series.

prefix [str, optional] Prefix to add to column numbers when no header, e.g. 'X' for X0, X1, ...

mangle_dupe_cols [bool, default True] Duplicate columns will be specified as 'X', 'X.1', ... 'X.N', rather than 'X'... 'X'. Passing in False will cause data to be overwritten if there are duplicate names in the columns.

dtype [Type name or dict of column -> type, optional] Data type for data or columns. E.g. {'a': np.float64, 'b': np.int32, 'c': 'Int64'} Use *str* or *object* together with suitable *na_values* settings to preserve and not interpret *dtype*. If converters are specified, they will be applied INSTEAD of *dtype* conversion.

engine [{‘c’, ‘python’}, optional] Parser engine to use. The C engine is faster while the python engine is currently more feature-complete.

converters [dict, optional] Dict of functions for converting values in certain columns. Keys can either be integers or column labels.

true_values [list, optional] Values to consider as True.

false_values [list, optional] Values to consider as False.

skipinitialspace [bool, default False] Skip spaces after delimiter.

skiprows [list-like, int or callable, optional] Line numbers to skip (0-indexed) or number of lines to skip (int) at the start of the file.

If callable, the callable function will be evaluated against the row indices, returning True if the row should be skipped and False otherwise. An example of a valid callable argument would be `lambda x: x in [0, 2]`.

skipfooter [int, default 0] Number of lines at bottom of file to skip (Unsupported with *engine='c'*).

nrows [int, optional] Number of rows of file to read. Useful for reading pieces of large files.

na_values [scalar, str, list-like, or dict, optional] Additional strings to recognize as NA/NaN. If dict passed, specific per-column NA values. By default the following values are interpreted as NaN: ‘’, ‘#N/A’, ‘#N/A N/A’, ‘#NA’, ‘-1.#IND’, ‘-1.#QNAN’, ‘-NaN’, ‘-nan’, ‘1.#IND’, ‘1.#QNAN’, ‘<NA>’, ‘N/A’, ‘NA’, ‘NULL’, ‘NaN’, ‘n/a’, ‘nan’, ‘null’.

keep_default_na [bool, default True] Whether or not to include the default NaN values when parsing the data. Depending on whether *na_values* is passed in, the behavior is as follows:

- If *keep_default_na* is True, and *na_values* are specified, *na_values* is appended to the default NaN values used for parsing.

- If `keep_default_na` is True, and `na_values` are not specified, only the default NaN values are used for parsing.
- If `keep_default_na` is False, and `na_values` are specified, only the NaN values specified in `na_values` are used for parsing.
- If `keep_default_na` is False, and `na_values` are not specified, no strings will be parsed as NaN.

Note that if `na_filter` is passed in as False, the `keep_default_na` and `na_values` parameters will be ignored.

na_filter [bool, default True] Detect missing value markers (empty strings and the value of `na_values`). In data without any NAs, passing `na_filter=False` can improve the performance of reading a large file.

verbose [bool, default False] Indicate number of NA values placed in non-numeric columns.

skip_blank_lines [bool, default True] If True, skip over blank lines rather than interpreting as NaN values.

parse_dates [bool or list of int or names or list of lists or dict, default False] The behavior is as follows:

- boolean. If True -> try parsing the index.
- list of int or names. e.g. If [1, 2, 3] -> try parsing columns 1, 2, 3 each as a separate date column.
- list of lists. e.g. If [[1, 3]] -> combine columns 1 and 3 and parse as a single date column.
- dict, e.g. {'foo' : [1, 3]} -> parse columns 1, 3 as date and call result 'foo'

If a column or index cannot be represented as an array of datetimes, say because of an unparseable value or a mixture of timezones, the column or index will be returned unaltered as an object data type. For non-standard datetime parsing, use `pd.to_datetime` after `pd.read_csv`. To parse an index or column with a mixture of timezones, specify `date_parser` to be a partially-applied `pandas.to_datetime()` with `utc=True`. See [Parsing a CSV with mixed timezones](#) for more.

Note: A fast-path exists for iso8601-formatted dates.

infer_datetime_format [bool, default False] If True and `parse_dates` is enabled, pandas will attempt to infer the format of the datetime strings in the columns, and if it can be inferred, switch to a faster method of parsing them. In some cases this can increase the parsing speed by 5-10x.

keep_date_col [bool, default False] If True and `parse_dates` specifies combining multiple columns then keep the original columns.

date_parser [function, optional] Function to use for converting a sequence of string columns to an array of datetime instances. The default uses `dateutil.parser.parser` to do the conversion. Pandas will try to call `date_parser` in three different ways, advancing to the next if an exception occurs: 1) Pass one or more arrays (as defined by `parse_dates`) as arguments; 2) concatenate (row-wise) the string values from the columns defined by `parse_dates` into a single array and pass that; and 3) call `date_parser` once for each row using one or more strings (corresponding to the columns defined by `parse_dates`) as arguments.

dayfirst [bool, default False] DD/MM format dates, international and European format.

cache_dates [bool, default True] If True, use a cache of unique, converted dates to apply the datetime conversion. May produce significant speed-up when parsing duplicate date strings, especially ones with timezone offsets.

New in version 0.25.0.

iterator [bool, default False] Return TextFileReader object for iteration or getting chunks with `get_chunk()`.

chunksize [int, optional] Return TextFileReader object for iteration. See the [IO Tools docs](#) for more information on `iterator` and `chunksize`.

compression [{‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}, default ‘infer’] For on-the-fly decompression of on-disk data. If ‘infer’ and `filepath_or_buffer` is path-like, then detect compression from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’, or ‘.xz’ (otherwise no decompression). If using ‘zip’, the ZIP file must contain only one data file to be read in. Set to None for no decompression.

thousands [str, optional] Thousands separator.

decimal [str, default ‘.’] Character to recognize as decimal point (e.g. use ‘,’ for European data).

lineterminator [str (length 1), optional] Character to break file into lines. Only valid with C parser.

quotechar [str (length 1), optional] The character used to denote the start and end of a quoted item. Quoted items can include the delimiter and it will be ignored.

quoting [int or csv.QUOTE_* instance, default 0] Control field quoting behavior per `csv.QUOTE_*` constants. Use one of QUOTE_MINIMAL (0), QUOTE_ALL (1), QUOTE_NONNUMERIC (2) or QUOTE_NONE (3).

doublequote [bool, default True] When quotechar is specified and quoting is not QUOTE_NONE, indicate whether or not to interpret two consecutive quotechar elements INSIDE a field as a single quotechar element.

escapechar [str (length 1), optional] One-character string used to escape other characters.

comment [str, optional] Indicates remainder of line should not be parsed. If found at the beginning of a line, the line will be ignored altogether. This parameter must be a single character. Like empty lines (as long as `skip_blank_lines=True`), fully commented lines are ignored by the parameter `header` but not by `skiprows`. For example, if `comment='#'`, parsing `#empty\na,b,c\n1,2,3` with `header=0` will result in ‘a,b,c’ being treated as the header.

encoding [str, optional] Encoding to use for UTF when reading/writing (ex. ‘utf-8’). [List of Python standard encodings](#).

dialect [str or csv.Dialect, optional] If provided, this parameter will override values (default or not) for the following parameters: `delimiter`, `doublequote`, `escapechar`, `skipinitialspace`, `quotechar`, and `quoting`. If it is necessary to override values, a ParserWarning will be issued. See `csv.Dialect` documentation for more details.

error_bad_lines [bool, default True] Lines with too many fields (e.g. a csv line with too many commas) will by default cause an exception to be raised, and no DataFrame will be returned. If False, then these “bad lines” will be dropped from the DataFrame that is returned.

warn_bad_lines [bool, default True] If `error_bad_lines` is False, and `warn_bad_lines` is True, a warning for each “bad line” will be output.

delim_whitespace [bool, default False] Specifies whether or not whitespace (e.g. ‘ ’ or ‘ ’) will be used as the sep. Equivalent to setting `sep='\\s+'`. If this option is set to True, nothing should be passed in for the `delimiter` parameter.

low_memory [bool, default True] Internally process the file in chunks, resulting in lower memory use while parsing, but possibly mixed type inference. To ensure no mixed types either

set False, or specify the type with the `dtype` parameter. Note that the entire file is read into a single DataFrame regardless, use the `chunksize` or `iterator` parameter to return the data in chunks. (Only valid with C parser).

memory_map [bool, default False] If a filepath is provided for `filepath_or_buffer`, map the file object directly onto memory and access the data directly from there. Using this option can improve performance because there is no longer any I/O overhead.

float_precision [str, optional] Specifies which converter the C engine should use for floating-point values. The options are `None` for the ordinary converter, `high` for the high-precision converter, and `round_trip` for the round-trip converter.

Returns

DataFrame or TextParser A comma-separated values (csv) file is returned as two-dimensional data structure with labeled axes.

See also:

to_csv Write DataFrame to a comma-separated values (csv) file.

read_csv Read a comma-separated values (csv) file into DataFrame.

read_fwf Read a table of fixed-width formatted lines into DataFrame.

Examples

```
>>> pd.read_csv('data.csv')
```

pandas.read_fwf

```
pandas.read_fwf(filepath_or_buffer: Union[str, pathlib.Path, IO[~AnyStr]], colspecs='infer', widths=None, infer_nrows=100, **kwds)
```

Read a table of fixed-width formatted lines into DataFrame.

Also supports optionally iterating or breaking of the file into chunks.

Additional help can be found in the [online docs for IO Tools](#).

Parameters

filepath_or_buffer [str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file:///localhost/path/to/table.csv`.

If you want to pass in a path object, pandas accepts any `os.PathLike`.

By file-like object, we refer to objects with a `read()` method, such as a file handler (e.g. via builtin `open` function) or `StringIO`.

colspecs [list of tuple (int, int) or ‘infer’. optional] A list of tuples giving the extents of the fixed-width fields of each line as half-open intervals (i.e., [from, to[). String value ‘infer’ can be used to instruct the parser to try detecting the column specifications from the first 100 rows of the data which are not being skipped via `skiprows` (default=‘infer’).

widths [list of int, optional] A list of field widths which can be used instead of ‘colspecs’ if the intervals are contiguous.

infer_nrows [int, default 100] The number of rows to consider when letting the parser determine the *cols*pecs.

New in version 0.24.0.

****kwds** [optional] Optional keyword arguments can be passed to `TextFileReader`.

Returns

DataFrame or TextParser A comma-separated values (csv) file is returned as two-dimensional data structure with labeled axes.

See also:

`to_csv` Write DataFrame to a comma-separated values (csv) file.

`read_csv` Read a comma-separated values (csv) file into DataFrame.

Examples

```
>>> pd.read_fwf('data.csv')
```

4.1.3 Clipboard

`read_clipboard([sep])`

Read text from clipboard and pass to `read_csv`.

pandas.read_clipboard

`pandas.read_clipboard(sep='s+', **kwargs)`

Read text from clipboard and pass to `read_csv`.

Parameters

sep [str, default ‘s+’] A string or regex delimiter. The default of ‘s+’ denotes one or more whitespace characters.

****kwargs** See `read_csv` for the full argument list.

Returns

DataFrame A parsed DataFrame object.

4.1.4 Excel

`read_excel(io[, sheet_name, header, names, ...])` Read an Excel file into a pandas DataFrame.

`ExcelFile.parse(self[, sheet_name, header, ...])` Parse specified sheet(s) into a DataFrame.

`pandas.read_excel`

```
pandas.read_excel(io, sheet_name=0, header=0, names=None, index_col=None, usecols=None,
                  squeeze=False, dtype=None, engine=None, converters=None, true_values=None,
                  false_values=None, skiprows=None, nrows=None, na_values=None,
                  keep_default_na=True, verbose=False, parse_dates=False, date_parser=None,
                  thousands=None, comment=None, skipfooter=0, convert_float=True, man-
                  gle_dupe_cols=True, **kwds)
```

Read an Excel file into a pandas DataFrame.

Supports `xls`, `xlsx`, `xlsm`, `xlsb`, and `odf` file extensions read from a local filesystem or URL. Supports an option to read a single sheet or a list of sheets.

Parameters

io [str, bytes, ExcelFile, xlrd.Book, path object, or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file://localhost/path/to/table.xlsx`.

If you want to pass in a path object, pandas accepts any `os.PathLike`.

By file-like object, we refer to objects with a `read()` method, such as a file handler (e.g. via builtin `open` function) or `StringIO`.

sheet_name [str, int, list, or None, default 0] Strings are used for sheet names. Integers are used in zero-indexed sheet positions. Lists of strings/integers are used to request multiple sheets. Specify None to get all sheets.

Available cases:

- Defaults to 0: 1st sheet as a `DataFrame`
- 1: 2nd sheet as a `DataFrame`
- "Sheet1": Load sheet with name "Sheet1"
- [0, 1, "Sheet5"]: Load first, second and sheet named "Sheet5" as a dict of `DataFrame`
- None: All sheets.

header [int, list of int, default 0] Row (0-indexed) to use for the column labels of the parsed DataFrame. If a list of integers is passed those row positions will be combined into a `MultiIndex`. Use None if there is no header.

names [array-like, default None] List of column names to use. If file contains no header row, then you should explicitly pass `header=None`.

index_col [int, list of int, default None] Column (0-indexed) to use as the row labels of the DataFrame. Pass None if there is no such column. If a list is passed, those columns will be combined into a `MultiIndex`. If a subset of data is selected with `usecols`, `index_col` is based on the subset.

usecols [int, str, list-like, or callable default None]

- If None, then parse all columns.
- If str, then indicates comma separated list of Excel column letters and column ranges (e.g. "A:E" or "A,C,E:F"). Ranges are inclusive of both sides.
- If list of int, then indicates list of column numbers to be parsed.

- If list of string, then indicates list of column names to be parsed.
New in version 0.24.0.
- If callable, then evaluate each column name against it and parse the column if the callable returns True.

Returns a subset of the columns according to behavior above.

New in version 0.24.0.

squeeze [bool, default False] If the parsed data only contains one column then return a Series.

dtype [Type name or dict of column -> type, default None] Data type for data or columns.
E.g. {'a': np.float64, 'b': np.int32} Use *object* to preserve data as stored in Excel and not interpret dtype. If converters are specified, they will be applied INSTEAD of dtype conversion.

engine [str, default None] If io is not a buffer or path, this must be set to identify io. Acceptable values are None, "xlrd", "openpyxl" or "odf".

converters [dict, default None] Dict of functions for converting values in certain columns. Keys can either be integers or column labels, values are functions that take one input argument, the Excel cell content, and return the transformed content.

true_values [list, default None] Values to consider as True.

false_values [list, default None] Values to consider as False.

skiprows [list-like] Rows to skip at the beginning (0-indexed).

nrows [int, default None] Number of rows to parse.

New in version 0.23.0.

na_values [scalar, str, list-like, or dict, default None] Additional strings to recognize as NA/NaN. If dict passed, specific per-column NA values. By default the following values are interpreted as NaN: '', '#N/A', '#N/A N/A', '#NA', '-1.#IND', '-1.#QNAN', '-NaN', '-nan', '1.#IND', '1.#QNAN', '<NA>', 'N/A', 'NA', 'NULL', 'NaN', 'n/a', 'nan', 'null'.

keep_default_na [bool, default True] Whether or not to include the default NaN values when parsing the data. Depending on whether *na_values* is passed in, the behavior is as follows:

- If *keep_default_na* is True, and *na_values* are specified, *na_values* is appended to the default NaN values used for parsing.
- If *keep_default_na* is True, and *na_values* are not specified, only the default NaN values are used for parsing.
- If *keep_default_na* is False, and *na_values* are specified, only the NaN values specified *na_values* are used for parsing.
- If *keep_default_na* is False, and *na_values* are not specified, no strings will be parsed as NaN.

Note that if *na_filter* is passed in as False, the *keep_default_na* and *na_values* parameters will be ignored.

na_filter [bool, default True] Detect missing value markers (empty strings and the value of *na_values*). In data without any NAs, passing *na_filter*=False can improve the performance of reading a large file.

verbose [bool, default False] Indicate number of NA values placed in non-numeric columns.

parse_dates [bool, list-like, or dict, default False] The behavior is as follows:

- bool. If True -> try parsing the index.
- list of int or names. e.g. If [1, 2, 3] -> try parsing columns 1, 2, 3 each as a separate date column.
- list of lists. e.g. If [[1, 3]] -> combine columns 1 and 3 and parse as a single date column.
- dict, e.g. {'foo' : [1, 3]} -> parse columns 1, 3 as date and call result 'foo'

If a column or index contains an unparseable date, the entire column or index will be returned unaltered as an object data type. If you don't want to parse some cells as date just change their type in Excel to "Text". For non-standard datetime parsing, use pd.`to_datetime` after pd.`read_excel`.

Note: A fast-path exists for iso8601-formatted dates.

date_parser [function, optional] Function to use for converting a sequence of string columns to an array of datetime instances. The default uses `dateutil.parser.parser` to do the conversion. Pandas will try to call `date_parser` in three different ways, advancing to the next if an exception occurs: 1) Pass one or more arrays (as defined by `parse_dates`) as arguments; 2) concatenate (row-wise) the string values from the columns defined by `parse_dates` into a single array and pass that; and 3) call `date_parser` once for each row using one or more strings (corresponding to the columns defined by `parse_dates`) as arguments.

thousands [str, default None] Thousands separator for parsing string columns to numeric. Note that this parameter is only necessary for columns stored as TEXT in Excel, any numeric columns will automatically be parsed, regardless of display format.

comment [str, default None] Comments out remainder of line. Pass a character or characters to this argument to indicate comments in the input file. Any data between the comment string and the end of the current line is ignored.

skipfooter [int, default 0] Rows at the end to skip (0-indexed).

convert_float [bool, default True] Convert integral floats to int (i.e., 1.0 -> 1). If False, all numeric data will be read in as floats: Excel stores all numbers as floats internally.

mangle_dupe_cols [bool, default True] Duplicate columns will be specified as 'X', 'X.1', ... 'X.N', rather than 'X'... 'X'. Passing in False will cause data to be overwritten if there are duplicate names in the columns.

****kwds** [optional] Optional keyword arguments can be passed to `TextFileReader`.

Returns

DataFrame or dict of DataFrames DataFrame from the passed in Excel file. See notes in `sheet_name` argument for more information on when a dict of DataFrames is returned.

See also:

`to_excel` Write DataFrame to an Excel file.

`to_csv` Write DataFrame to a comma-separated values (csv) file.

`read_csv` Read a comma-separated values (csv) file into DataFrame.

`read_fwf` Read a table of fixed-width formatted lines into DataFrame.

Examples

The file can be read using the file name as string or an open file object:

```
>>> pd.read_excel('tmp.xlsx', index_col=0)
      Name  Value
0  string1     1
1  string2     2
2 #Comment     3
```

```
>>> pd.read_excel(open('tmp.xlsx', 'rb'),
...                  sheet_name='Sheet3')
   Unnamed: 0    Name  Value
0            0  string1     1
1            1  string2     2
2            2 #Comment     3
```

Index and header can be specified via the *index_col* and *header* arguments

```
>>> pd.read_excel('tmp.xlsx', index_col=None, header=None)
      0    1    2
0  NaN  Name  Value
1  0.0  string1     1
2  1.0  string2     2
3  2.0 #Comment     3
```

Column types are inferred but can be explicitly specified

```
>>> pd.read_excel('tmp.xlsx', index_col=0,
...                  dtype={'Name': str, 'Value': float})
      Name  Value
0  string1    1.0
1  string2    2.0
2 #Comment    3.0
```

True, False, and NA values, and thousands separators have defaults, but can be explicitly specified, too. Supply the values you would like as strings or lists of strings!

```
>>> pd.read_excel('tmp.xlsx', index_col=0,
...                  na_values=['string1', 'string2'])
      Name  Value
0    NaN     1
1    NaN     2
2 #Comment     3
```

Comment lines in the excel input file can be skipped using the *comment* kwarg

```
>>> pd.read_excel('tmp.xlsx', index_col=0, comment='#')
      Name  Value
0  string1    1.0
1  string2    2.0
2    None    NaN
```

pandas.ExcelFile.parse

```
ExcelFile.parse(self, sheet_name=0, header=0, names=None, index_col=None, usecols=None,
                 squeeze=False, converters=None, true_values=None, false_values=None,
                 skiprows=None, nrows=None, na_values=None, parse_dates=False,
                 date_parser=None, thousands=None, comment=None, skipfooter=0, convert_float=True, mangle_dupe_cols=True, **kwds)
```

Parse specified sheet(s) into a DataFrame.

Equivalent to read_excel(ExcelFile, ...) See the read_excel docstring for more info on accepted parameters.

Returns

DataFrame or dict of DataFrames DataFrame from the passed in Excel file.

ExcelWriter (path[, engine, date_format, ...])	Class for writing DataFrame objects into excel sheets.
--	--

pandas.ExcelWriter

```
class pandas.ExcelWriter(path, engine=None, date_format=None, datetime_format=None,
                           mode='w', **engine_kwargs)
```

Class for writing DataFrame objects into excel sheets.

Default is to use xlwt for xls, openpyxl for xlsx. See DataFrame.to_excel for typical usage.

Parameters

path [str] Path to xls or xlsx file.

engine [str (optional)] Engine to use for writing. If None, defaults to `io.excel.<extension>.writer`. NOTE: can only be passed as a keyword argument.

date_format [str, default None] Format string for dates written into Excel files (e.g. ‘YYYY-MM-DD’).

datetime_format [str, default None] Format string for datetime objects written into Excel files. (e.g. ‘YYYY-MM-DD HH:MM:SS’).

mode [{‘w’, ‘a’}, default ‘w’] File mode to use (write or append).

New in version 0.24.0.

Notes

None of the methods and properties are considered public.

For compatibility with CSV writers, ExcelWriter serializes lists and dicts to strings before writing.

Examples

Default usage:

```
>>> with ExcelWriter('path_to_file.xlsx') as writer:  
...     df.to_excel(writer)
```

To write to separate sheets in a single file:

```
>>> with ExcelWriter('path_to_file.xlsx') as writer:  
...     df1.to_excel(writer, sheet_name='Sheet1')  
...     df2.to_excel(writer, sheet_name='Sheet2')
```

You can set the date format or datetime format:

```
>>> with ExcelWriter('path_to_file.xlsx',  
...                     date_format='YYYY-MM-DD',  
...                     datetime_format='YYYY-MM-DD HH:MM:SS') as writer:  
...     df.to_excel(writer)
```

You can also append to an existing Excel file:

```
>>> with ExcelWriter('path_to_file.xlsx', mode='a') as writer:  
...     df.to_excel(writer, sheet_name='Sheet3')
```

Attributes

None	<input type="button" value=""/>
-------------	---------------------------------

Methods

None	<input type="button" value=""/>
-------------	---------------------------------

4.1.5 JSON

<code>read_json([path_or_buf, orient, typ, dtype, ...])</code>	Convert a JSON string to pandas object.
<code>json_normalize(data, List[Dict], ...)</code>	Normalize semi-structured JSON data into a flat table.

pandas.read_json

`pandas.read_json(path_or_buf=None, orient=None, typ='frame', dtype=None, convert_axes=None, convert_dates=True, keep_default_dates=True, numpy=False, precise_float=False, date_unit=None, encoding=None, lines=False, chunksize=None, compression='infer')`

Convert a JSON string to pandas object.

Parameters

path_or_buf [a valid JSON str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For

file URLs, a host is expected. A local file could be: `file://localhost/path/to/table.json`.

If you want to pass in a path object, pandas accepts any `os.PathLike`.

By file-like object, we refer to objects with a `read()` method, such as a file handler (e.g. via builtin `open` function) or `StringIO`.

orient [str] Indication of expected JSON string format. Compatible JSON strings can be produced by `to_json()` with a corresponding orient value. The set of possible orients is:

- 'split': dict like {index -> [index], columns -> [columns], data -> [values]}
- 'records' : list like [{column -> value}, ... , {column -> value}]
- 'index' : dict like {index -> {column -> value}}
- 'columns' : dict like {column -> {index -> value}}
- 'values' : just the values array

The allowed and default values depend on the value of the `typ` parameter.

- when `typ == 'series'`,
 - allowed orients are {'split', 'records', 'index'}
 - default is 'index'
 - The Series index must be unique for orient 'index'.
- when `typ == 'frame'`,
 - allowed orients are {'split', 'records', 'index', 'columns', 'values', 'table'}
 - default is 'columns'
 - The DataFrame index must be unique for orients 'index' and 'columns'.
 - The DataFrame columns must be unique for orients 'index', 'columns', and 'records'.

New in version 0.23.0: 'table' as an allowed value for the `orient` argument

typ [{‘frame’, ‘series’}, default ‘frame’] The type of object to recover.

dtype [bool or dict, default None] If True, infer dtypes; if a dict of column to dtype, then use those; if False, then don’t infer dtypes at all, applies only to the data.

For all `orient` values except 'table', default is True.

Changed in version 0.25.0: Not applicable for `orient='table'`.

convert_axes [bool, default None] Try to convert the axes to the proper dtypes.

For all `orient` values except 'table', default is True.

Changed in version 0.25.0: Not applicable for `orient='table'`.

convert_dates [bool or list of str, default True] List of columns to parse for dates. If True, then try to parse datelike columns. A column label is datelike if

- it ends with '_at',
- it ends with '_time',

- it begins with 'timestamp',
- it is 'modified', or
- it is 'date'.

keep_default_dates [bool, default True] If parsing dates, then parse the default datelike columns.

numpy [bool, default False] Direct decoding to numpy arrays. Supports numeric data only, but non-numeric column and index labels are supported. Note also that the JSON ordering MUST be the same for each term if numpy=True.

Deprecated since version 1.0.0.

precise_float [bool, default False] Set to enable usage of higher precision (strtod) function when decoding string to double values. Default (False) is to use fast but less precise builtin functionality.

date_unit [str, default None] The timestamp unit to detect if converting dates. The default behaviour is to try and detect the correct precision, but if this is not desired then pass one of 's', 'ms', 'us' or 'ns' to force parsing only seconds, milliseconds, microseconds or nanoseconds respectively.

encoding [str, default is ‘utf-8’] The encoding to use to decode py3 bytes.

lines [bool, default False] Read the file as a json object per line.

chunksize [int, optional] Return JsonReader object for iteration. See the [line-delimited json docs](#) for more information on chunksize. This can only be passed if *lines=True*. If this is None, the file will be read into memory all at once.

New in version 0.21.0.

compression [{‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}, default ‘infer’] For on-the-fly decompression of on-disk data. If ‘infer’, then use gzip, bz2, zip or xz if path_or_buf is a string ending in ‘.gz’, ‘.bz2’, ‘.zip’, or ‘xz’, respectively, and no decompression otherwise. If using ‘zip’, the ZIP file must contain only one data file to be read in. Set to None for no decompression.

New in version 0.21.0.

Returns

Series or DataFrame The type returned depends on the value of *typ*.

See also:

[**DataFrame.to_json**](#) Convert a DataFrame to a JSON string.

[**Series.to_json**](#) Convert a Series to a JSON string.

Notes

Specific to `orient='table'`, if a `DataFrame` with a literal `Index` name of `index` gets written with `to_json()`, the subsequent read operation will incorrectly set the `Index` name to `None`. This is because `index` is also used by `DataFrame.to_json()` to denote a missing `Index` name, and the subsequent `read_json()` operation cannot distinguish between the two. The same limitation is encountered with a `MultiIndex` and any names beginning with 'level_'.

Examples

```
>>> df = pd.DataFrame([['a', 'b'], ['c', 'd']],
...                     index=['row 1', 'row 2'],
...                     columns=['col 1', 'col 2'])
```

Encoding/decoding a Dataframe using 'split' formatted JSON:

```
>>> df.to_json(orient='split')
'{"columns": ["col 1", "col 2"],
 "index": ["row 1", "row 2"],
 "data": [[{"a": "a", "b": "b"}, {"a": "c", "b": "d"}]}'
>>> pd.read_json(_, orient='split')
   col 1 col 2
row 1      a      b
row 2      c      d
```

Encoding/decoding a Dataframe using 'index' formatted JSON:

```
>>> df.to_json(orient='index')
'{"row 1": {"col 1": "a", "col 2": "b"}, "row 2": {"col 1": "c", "col 2": "d"}}'
>>> pd.read_json(_, orient='index')
   col 1 col 2
row 1      a      b
row 2      c      d
```

Encoding/decoding a Dataframe using 'records' formatted JSON. Note that index labels are not preserved with this encoding.

```
>>> df.to_json(orient='records')
'[{"col 1": "a", "col 2": "b"}, {"col 1": "c", "col 2": "d"}]'
>>> pd.read_json(_, orient='records')
   col 1 col 2
0      a      b
1      c      d
```

Encoding with Table Schema

```
>>> df.to_json(orient='table')
'{"schema": {"fields": [{"name": "index", "type": "string"}, {"name": "col 1", "type": "string"}, {"name": "col 2", "type": "string"}], "primaryKey": "index", "pandas_version": "0.20.0"}, "data": [{"index": "row 1", "col 1": "a", "col 2": "b"}, {"index": "row 2", "col 1": "c", "col 2": "d"}]}'
```

pandas.json_normalize

```
pandas.json_normalize(data: Union[Dict, List[Dict]], record_path: Union[str, List, NoneType]
                      = None, meta: Union[str, List[Union[str, List[str]]], NoneType] = None,
                      meta_prefix: Union[str, NoneType] = None, record_prefix: Union[str, None-
                      Type] = None, errors: Union[str, NoneType] = 'raise', sep: str = '.', max_level:
                      Union[int, NoneType] = None) → DataFrame
```

Normalize semi-structured JSON data into a flat table.

Parameters

data [dict or list of dicts] Unserialized JSON objects.

record_path [str or list of str, default None] Path in each object to list of records. If not passed, data will be assumed to be an array of records.

meta [list of paths (str or list of str), default None] Fields to use as metadata for each record in resulting table.

meta_prefix [str, default None] If True, prefix records with dotted (?) path, e.g. foo.bar.field if meta is ['foo', 'bar'].

record_prefix [str, default None] If True, prefix records with dotted (?) path, e.g. foo.bar.field if path to records is ['foo', 'bar'].

errors [{‘raise’, ‘ignore’}, default ‘raise’] Configures error handling.

- ‘ignore’ : will ignore KeyError if keys listed in meta are not always present.
- ‘raise’ : will raise KeyError if keys listed in meta are not always present.

sep [str, default ‘.’] Nested records will generate names separated by sep. e.g., for sep=’,’, {‘foo’: {‘bar’: 0}} -> foo.bar.

max_level [int, default None] Max number of levels(depth of dict) to normalize. if None, normalizes all levels.

New in version 0.25.0.

Returns

frame [DataFrame]

Normalize semi-structured JSON data into a flat table.

Examples

```
>>> from pandas.io.json import json_normalize
>>> data = [{"id": 1, "name": {"first": "Coleen", "last": "Volk"}, "...": {"name": {"given": "Mose", "family": "Regner"}}, "...": {"id": 2, "name": "Faye Raker"}}
>>> json_normalize(data)
   id      name.name.family name.name.first name.name.given name.name.last
0  1.0        NaN          NaN    Coleen        NaN       Volk
1  NaN        NaN          Regner        NaN      Mose        NaN
2  2.0  Faye Raker        NaN          NaN        NaN       NaN
```

```
>>> data = [{"id": 1, "...": {"name": "Cole Volk", "...": {"fitness": {"height": 130, "weight": 60}}}, ...}
```

(continues on next page)

(continued from previous page)

```

...
    {'name': "Mose Reg",
     'fitness': {'height': 130, 'weight': 60}},
    {'id': 2, 'name': 'Faye Raker',
     'fitness': {'height': 130, 'weight': 60}}]
>>> json_normalize(data, max_level=0)
   fitness           id      name
0  {'height': 130, 'weight': 60}  1.0  Cole Volk
1  {'height': 130, 'weight': 60}  NaN  Mose Reg
2  {'height': 130, 'weight': 60}  2.0  Faye Raker

```

Normalizes nested data up to level 1.

```

>>> data = [{"id": 1,
...             "name": "Cole Volk",
...             "fitness": {"height": 130, "weight": 60}},
...             {"name": "Mose Reg",
...             "fitness": {"height": 130, "weight": 60}},
...             {"id": 2, "name": "Faye Raker",
...             "fitness": {"height": 130, "weight": 60}}]
>>> json_normalize(data, max_level=1)
   fitness.height  fitness.weight  id      name
0        130            60      1.0  Cole Volk
1        130            60      NaN  Mose Reg
2        130            60      2.0  Faye Raker

```

```

>>> data = [{"state": 'Florida',
...             'shortname': 'FL',
...             'info': {'governor': 'Rick Scott'},
...             'counties': [{"name": 'Dade', 'population': 12345},
...                         {"name": 'Broward', 'population': 40000},
...                         {"name": 'Palm Beach', 'population': 60000}]},
...             {"state": 'Ohio',
...             'shortname': 'OH',
...             'info': {'governor': 'John Kasich'},
...             'counties': [{"name": 'Summit', 'population': 1234},
...                         {"name": 'Cuyahoga', 'population': 1337}]}]
>>> result = json_normalize(data, 'counties', ['state', 'shortname',
...                                                 ['info', 'governor']])
>>> result
       name  population      state shortname info.governor
0      Dade       12345  Florida      FL    Rick Scott
1    Broward      40000  Florida      FL    Rick Scott
2  Palm Beach      60000  Florida      FL    Rick Scott
3    Summit       1234    Ohio        OH  John Kasich
4   Cuyahoga      1337    Ohio        OH  John Kasich

```

```

>>> data = {'A': [1, 2]}
>>> json_normalize(data, 'A', record_prefix='Prefix.')
  Prefix.0
0        1
1        2

```

Returns normalized data with columns prefixed with the given string.

<code>build_table_schema(data[, index, ...])</code>	Create a Table schema from data.
---	----------------------------------

pandas.io.json.build_table_schema

`pandas.io.json.build_table_schema(data, index=True, primary_key=None, version=True)`
Create a Table schema from data.

Parameters

- data** [Series, DataFrame]
- index** [bool, default True] Whether to include `data.index` in the schema.
- primary_key** [bool or None, default True] Column names to designate as the primary key. The default `None` will set '`primaryKey`' to the index level or levels if the index is unique.
- version** [bool, default True] Whether to include a field `pandas_version` with the version of pandas that generated the schema.

Returns

- schema** [dict]

Notes

See `_as_json_table_type` for conversion types. Timedeltas as converted to ISO8601 duration format with 9 decimal places after the seconds field for nanosecond precision.

Categoricals are converted to the `any` dtype, and use the `enum` field constraint to list the allowed values. The `ordered` attribute is included in an `ordered` field.

Examples

```
>>> df = pd.DataFrame(
...     {'A': [1, 2, 3],
...      'B': ['a', 'b', 'c'],
...      'C': pd.date_range('2016-01-01', freq='d', periods=3),
...      }, index=pd.Index(range(3), name='idx'))
>>> build_table_schema(df)
{'fields': [{"name": "idx", "type": "integer"}, {"name": "A", "type": "integer"}, {"name": "B", "type": "string"}, {"name": "C", "type": "datetime"}], "pandas_version": "0.20.0", "primaryKey": ["idx"]}
```

4.1.6 HTML

<code>read_html(io[, match, flavor, header, ...])</code>	Read HTML tables into a list of DataFrame objects.
--	--

`pandas.read_html`

```
pandas.read_html(io, match='.+', flavor=None, header=None, index_col=None, skiprows=None, attrs=None, parse_dates=False, thousands=',', encoding=None, decimal=',', converters=None, na_values=None, keep_default_na=True, displayed_only=True)
```

Read HTML tables into a list of DataFrame objects.

Parameters

io [str, path object or file-like object] A URL, a file-like object, or a raw string containing HTML. Note that lxml only accepts the http, ftp and file url protocols. If you have a URL that starts with 'https' you might try removing the 's'.

match [str or compiled regular expression, optional] The set of tables containing text matching this regex or string will be returned. Unless the HTML is extremely simple you will probably need to pass a non-empty string here. Defaults to '.+' (match any non-empty string). The default value will return all tables contained on a page. This value is converted to a regular expression so that there is consistent behavior between BeautifulSoup and lxml.

flavor [str or None] The parsing engine to use. ‘bs4’ and ‘html5lib’ are synonymous with each other, they are both there for backwards compatibility. The default of `None` tries to use `lxml` to parse and if that fails it falls back on `bs4 + html5lib`.

header [int or list-like or `None`, optional] The row (or list of rows for a `MultiIndex`) to use to make the columns headers.

index_col [int or list-like or `None`, optional] The column (or list of columns) to use to create the index.

skiprows [int or list-like or slice or `None`, optional] Number of rows to skip after parsing the column integer. 0-based. If a sequence of integers or a slice is given, will skip the rows indexed by that sequence. Note that a single element sequence means ‘skip the nth row’ whereas an integer means ‘skip n rows’.

attrs [dict or `None`, optional] This is a dictionary of attributes that you can pass to use to identify the table in the HTML. These are not checked for validity before being passed to lxml or BeautifulSoup. However, these attributes must be valid HTML table attributes to work correctly. For example,

```
attrs = {'id': 'table'}
```

is a valid attribute dictionary because the ‘id’ HTML tag attribute is a valid HTML attribute for *any* HTML tag as per [this document](#).

```
attrs = {'asdf': 'table'}
```

is *not* a valid attribute dictionary because ‘asdf’ is not a valid HTML attribute even if it is a valid XML attribute. Valid HTML 4.01 table attributes can be found [here](#). A working draft of the HTML 5 spec can be found [here](#). It contains the latest information on table attributes for the modern web.

parse_dates [bool, optional] See `read_csv()` for more details.

thousands [str, optional] Separator to use to parse thousands. Defaults to ' , '.

encoding [str or None, optional] The encoding used to decode the web page. Defaults to None. ``None`` preserves the previous encoding behavior, which depends on the underlying parser library (e.g., the parser library will try to use the encoding provided by the document).

decimal [str, default '.'] Character to recognize as decimal point (e.g. use ',' for European data).

converters [dict, default None] Dict of functions for converting values in certain columns. Keys can either be integers or column labels, values are functions that take one input argument, the cell (not column) content, and return the transformed content.

na_values [iterable, default None] Custom NA values.

keep_default_na [bool, default True] If na_values are specified and keep_default_na is False the default NaN values are overridden, otherwise they're appended to.

displayed_only [bool, default True] Whether elements with "display: none" should be parsed.

Returns

dfs A list of DataFrames.

See also:

[read_csv](#)

Notes

Before using this function you should read the [gotchas about the HTML parsing libraries](#).

Expect to do some cleanup after you call this function. For example, you might need to manually assign column names if the column names are converted to NaN when you pass the `header=0` argument. We try to assume as little as possible about the structure of the table and push the idiosyncrasies of the HTML contained in the table to the user.

This function searches for `<table>` elements and only for `<tr>` and `<th>` rows and `<td>` elements within each `<tr>` or `<th>` element in the table. `<td>` stands for "table data". This function attempts to properly handle `colspan` and `rowspan` attributes. If the function has a `<thead>` argument, it is used to construct the header, otherwise the function attempts to find the header within the body (by putting rows with only `<th>` elements into the header).

New in version 0.21.0.

Similar to `read_csv()` the `header` argument is applied **after** `skiprows` is applied.

This function will *always* return a list of `DataFrame` or it will fail, e.g., it will *not* return an empty list.

Examples

See the `read_html` documentation in the IO section of the docs for some examples of reading in HTML tables.

4.1.7 HDFStore: PyTables (HDF5)

<code>read_hdf(path_or_buf[, key, where, columns, ...])</code>	Read from the store, close it if we opened it.
<code>HDFStore.put(self, key, value[, format, ...])</code>	Store object in HDFStore.
<code>HDFStore.append(self, key, value[, format, ...])</code>	Append to Table in file.
<code>HDFStore.get(self, key)</code>	Retrieve pandas object stored in file.
<code>HDFStore.select(self, key[, where, start, ...])</code>	Retrieve pandas object stored in file, optionally based on where criteria.
<code>HDFStore.info(self)</code>	Print detailed information on the store.
<code>HDFStore.keys(self)</code>	Return a list of keys corresponding to objects stored in HDFStore.
<code>HDFStore.groups(self)</code>	Return a list of all the top-level nodes.
<code>HDFStore.walk(self[, where])</code>	Walk the pytables group hierarchy for pandas objects.

pandas.read_hdf

```
pandas.read_hdf(path_or_buf, key=None, mode: str = 'r', errors: str = 'strict', where=None, start:  
    Union[int, NoneType] = None, stop: Union[int, NoneType] = None, columns=None,  
    iterator=False, chunksize: Union[int, NoneType] = None, **kwargs)
```

Read from the store, close it if we opened it.

Retrieve pandas object stored in file, optionally based on where criteria

Parameters

path_or_buf [str, path object, pandas.HDFStore or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file://localhost/path/to/table.h5`.

If you want to pass in a path object, pandas accepts any `os.PathLike`.

Alternatively, pandas accepts an open `pandas.HDFStore` object.

By file-like object, we refer to objects with a `read()` method, such as a file handler (e.g. via builtin `open` function) or `StringIO`.

New in version 0.21.0: support for `__fspath__` protocol.

key [object, optional] The group identifier in the store. Can be omitted if the HDF file contains a single pandas object.

mode [{‘r’, ‘r+’, ‘a’}, default ‘r’] Mode to use when opening the file. Ignored if `path_or_buf` is a `pandas.HDFStore`. Default is ‘r’.

where [list, optional] A list of Term (or convertible) objects.

start [int, optional] Row number to start selection.

stop [int, optional] Row number to stop selection.

columns [list, optional] A list of columns names to return.

iterator [bool, optional] Return an iterator object.

chunksize [int, optional] Number of rows to include in an iteration when using an iterator.

errors [str, default ‘strict’] Specifies how encoding and decoding errors are to be handled. See the `errors` argument for `open()` for a full list of options.

****kwargs** Additional keyword arguments passed to HDFStore.

Returns

item [object] The selected object. Return type depends on the object stored.

See also:

`DataFrame.to_hdf` Write a HDF file from a DataFrame.

`HDFStore` Low-level access to HDF files.

Examples

```
>>> df = pd.DataFrame([[1, 1.0, 'a']], columns=['x', 'y', 'z'])
>>> df.to_hdf('./store.h5', 'data')
>>> reread = pd.read_hdf('./store.h5')
```

pandas.HDFStore.put

`HDFStore.put(self, key: str, value: ~FrameOrSeries, format=None, index=True, append=False, complevel=None, complib=None, complevel: Union[int, NoneType] = None, min_itemsize: Union[int, Dict[str, int], NoneType] = None, nan_rep=None, data_columns: Union[List[str], NoneType] = None, encoding=None, errors: str = 'strict')`

Store object in HDFStore.

Parameters

key [str]

value [{Series, DataFrame}]

format ['fixed(f)table(t)', default is 'fixed']

fixed(f) [Fixed format] Fast writing/reading. Not-appendable, nor searchable.

table(t) [Table format] Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data.

append [bool, default False] This will force Table format, append the input data to the existing.

data_columns [list, default None] List of columns to create as data columns, or True to use all columns. See [here](#).

encoding [str, default None] Provide an encoding for strings.

dropna [bool, default False, do not write an ALL nan row to] The store settable by the option 'io.hdf.dropna_table'.

pandas.HDFStore.append

```
HDFStore.append(self, key: str, value: ~FrameOrSeries, format=None, axes=None, index=True, append=True, complib=None, complevel: Union[int, NoneType] = None, columns=None, min_itemsize: Union[int, Dict[str, int], NoneType] = None, nan_rep=None, chunksize=None, expectedrows=None, dropna: Union[bool, NoneType] = None, data_columns: Union[List[str], NoneType] = None, encoding=None, errors: str = 'strict')
```

Append to Table in file. Node must already exist and be Table format.

Parameters

key [str]

value [{ Series, DataFrame}]

format ['table' is the default]

table(t) [table format] Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data.

append [bool, default True] Append the input data to the existing.

data_columns [list of columns, or True, default None] List of columns to create as indexed data columns for on-disk queries, or True to use all columns. By default only the axes of the object are indexed. See [here](#).

min_itemsize [dict of columns that specify minimum string sizes]

nan_rep [string to use as string nan representation]

chunksize [size to chunk the writing]

expectedrows [expected TOTAL row size of this table]

encoding [default None, provide an encoding for strings]

dropna [bool, default False] Do not write an ALL nan row to the store settable by the option 'io.hdf.dropna_table'.

Notes

Does *not* check if data being appended overlaps with existing data in the table, so be careful

pandas.HDFStore.get

```
HDFStore.get(self, key: str)
```

Retrieve pandas object stored in file.

Parameters

key [str]

Returns

object Same type as object stored in file.

pandas.HDFStore.select

HDFStore.**select** (*self*, *key*: str, *where*=None, *start*=None, *stop*=None, *columns*=None, *iterator*=False, *chunksize*=None, *auto_close*: bool = False)
Retrieve pandas object stored in file, optionally based on where criteria.

Parameters

key [str] Object being retrieved from file.
where [list, default None] List of Term (or convertible) objects, optional.
start [int, default None] Row number to start selection.
stop [int, default None] Row number to stop selection.
columns [list, default None] A list of columns that if not None, will limit the return columns.
iterator [bool, default False] Returns an iterator.
chunksize [int, default None] Number or rows to include in iteration, return an iterator.
auto_close [bool, default False] Should automatically close the store when finished.

Returns

object Retrieved object from file.

pandas.HDFStore.info

HDFStore.**info** (*self*) → str
Print detailed information on the store.

New in version 0.21.0.

Returns

str

pandas.HDFStore.keys

HDFStore.**keys** (*self*) → List[str]
Return a list of keys corresponding to objects stored in HDFStore.

Returns

list List of ABSOLUTE path-names (e.g. have the leading '/').

pandas.HDFStore.groups

HDFStore.**groups** (*self*)
Return a list of all the top-level nodes.

Each node returned is not a pandas storage object.

Returns

list List of objects.

pandas.HDFStore.walk

HDFStore.**walk**(*self, where='/'*)

Walk the pytables group hierarchy for pandas objects.

This generator will yield the group path, subgroups and pandas object names for each group.

Any non-pandas PyTables objects that are not a group will be ignored.

The *where* group itself is listed first (preorder), then each of its child groups (following an alphanumerical order) is also traversed, following the same procedure.

New in version 0.24.0.

Parameters

where [str, default “/”] Group where to start walking.

Yields

path [str] Full path to a group (without trailing ‘/’).

groups [list] Names (strings) of the groups contained in *path*.

leaves [list] Names (strings) of the pandas objects contained in *path*.

4.1.8 Feather

`read_feather`(*path[, columns]*)

Load a feather-format object from the file path.

pandas.read_feather

pandas.**read_feather**(*path, columns=None, use_threads: bool = True*)

Load a feather-format object from the file path.

Parameters

path [str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file://localhost/path/to/table.feather`.

If you want to pass in a path object, pandas accepts any `os.PathLike`.

By file-like object, we refer to objects with a `read()` method, such as a file handler (e.g. via builtin `open` function) or `StringIO`.

columns [sequence, default None] If not provided, all columns are read.

New in version 0.24.0.

use_threads [bool, default True]

Whether to parallelize reading using multiple threads.

New in version 0.24.0.

Returns

type of object stored in file

4.1.9 Parquet

<code>read_parquet(path, engine[, columns])</code>	Load a parquet object from the file path, returning a DataFrame.
--	--

pandas.read_parquet

`pandas.read_parquet(path, engine: str = 'auto', columns=None, **kwargs)`

Load a parquet object from the file path, returning a DataFrame.

New in version 0.21.0.

Parameters

path [str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file://localhost/path/to/table.parquet`. A file URL can also be a path to a directory that contains multiple partitioned parquet files. Both pyarrow and fastparquet support paths to directories as well as file URLs. A directory path could be: `file://localhost/path/to/tables`

If you want to pass in a path object, pandas accepts any `os.PathLike`.

By file-like object, we refer to objects with a `read()` method, such as a file handler (e.g. via builtin `open` function) or `StringIO`.

engine [{‘auto’, ‘pyarrow’, ‘fastparquet’}, default ‘auto’] Parquet library to use. If ‘auto’, then the option `io.parquet.engine` is used. The default `io.parquet.engine` behavior is to try ‘pyarrow’, falling back to ‘fastparquet’ if ‘pyarrow’ is unavailable.

columns [list, default=None] If not None, only these columns will be read from the file.

New in version 0.21.1.

****kwargs** Any additional kwargs are passed to the engine.

Returns

`DataFrame`

4.1.10 ORC

<code>read_orc(path, pathlib.Path, IO[~AnyStr]), ...)</code>	Load an ORC object from the file path, returning a DataFrame.
--	---

pandas.read_orc

`pandas.read_orc(path: Union[str, pathlib.Path, IO[~AnyStr]], columns: Union[List[str], NoneType] = None, **kwargs) → 'DataFrame'`

Load an ORC object from the file path, returning a DataFrame.

New in version 1.0.0.

Parameters

path [str, path object or file-like object] Any valid string path is acceptable. The string could be

a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file://localhost/path/to/table.orc`.

If you want to pass in a path object, pandas accepts any `os.PathLike`.

By file-like object, we refer to objects with a `read()` method, such as a file handler (e.g. via builtin `open` function) or `StringIO`.

columns [list, default None] If not None, only these columns will be read from the file.

****kwargs** Any additional kwargs are passed to pyarrow.

Returns

`DataFrame`

4.1.11 SAS

<code>read_sas(filepath_or_buffer[, format, ...])</code>	Read SAS files stored as either XPORT or SAS7BDAT format files.
--	---

pandas.read_sas

`pandas.read_sas(filepath_or_buffer, format=None, index=None, encoding=None, chunksize=None, iterator=False)`

Read SAS files stored as either XPORT or SAS7BDAT format files.

Parameters

filepath_or_buffer [str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file://localhost/path/to/table.sas`.

If you want to pass in a path object, pandas accepts any `os.PathLike`.

By file-like object, we refer to objects with a `read()` method, such as a file handler (e.g. via builtin `open` function) or `StringIO`.

format [str {‘xport’, ‘sas7bdat’} or None] If None, file format is inferred from file extension. If ‘xport’ or ‘sas7bdat’, uses the corresponding format.

index [identifier of index column, defaults to None] Identifier of column that should be used as index of the DataFrame.

encoding [str, default is None] Encoding for text data. If None, text data are stored as raw bytes.

chunksize [int] Read file `chunksize` lines at a time, returns iterator.

iterator [bool, defaults to False] If True, returns an iterator for reading the file incrementally.

Returns

`DataFrame` if `iterator=False` and `chunksize=None`, else `SAS7BDATReader` or `XportReader`

4.1.12 SPSS

<code>read_spss(path, pathlib.Path], usecols, ...)</code>	Load an SPSS file from the file path, returning a DataFrame.
---	--

pandas.read_spss

`pandas.read_spss(path: Union[str, pathlib.Path], usecols: Union[Sequence[str], NoneType] = None, convert_categoricals: bool = True) → pandas.core.frame.DataFrame`

Load an SPSS file from the file path, returning a DataFrame.

New in version 0.25.0.

Parameters

path [string or Path] File path.

usecols [list-like, optional] Return a subset of the columns. If None, return all columns.

convert_categoricals [bool, default is True] Convert categorical columns into pd.Categorical.

Returns

DataFrame

4.1.13 SQL

<code>read_sql_table(table_name, con[, schema, ...])</code>	Read SQL database table into a DataFrame.
<code>read_sql_query(sql, con[, index_col, ...])</code>	Read SQL query into a DataFrame.
<code>read_sql(sql, con[, index_col, ...])</code>	Read SQL query or database table into a DataFrame.

pandas.read_sql_table

`pandas.read_sql_table(table_name, con, schema=None, index_col=None, coerce_float=True, parse_dates=None, columns=None, chunksize=None)`

Read SQL database table into a DataFrame.

Given a table name and a SQLAlchemy connectable, returns a DataFrame. This function does not support DBAPI connections.

Parameters

table_name [str] Name of SQL table in database.

con [SQLAlchemy connectable or str] A database URI could be provided as as str. SQLite DBAPI connection mode not supported.

schema [str, default None] Name of SQL schema in database to query (if database flavor supports this). Uses default schema if None (default).

index_col [str or list of str, optional, default: None] Column(s) to set as index(MultiIndex).

coerce_float [bool, default True] Attempts to convert values of non-string, non-numeric objects (like decimal.Decimal) to floating point. Can result in loss of Precision.

parse_dates [list or dict, default None]

- List of column names to parse as dates.

- Dict of {column_name: format string} where format string is strftime compatible in case of parsing string times or is one of (D, s, ns, ms, us) in case of parsing integer timestamps.
- Dict of {column_name: arg dict}, where the arg dict corresponds to the keyword arguments of `pandas.to_datetime()` Especially useful with databases without native Datetime support, such as SQLite.

columns [list, default None] List of column names to select from SQL table.

chunksize [int, default None] If specified, returns an iterator where `chunksize` is the number of rows to include in each chunk.

Returns

DataFrame A SQL table is returned as two-dimensional data structure with labeled axes.

See also:

`read_sql_query` Read SQL query into a DataFrame.

`read_sql` Read SQL query or database table into a DataFrame.

Notes

Any datetime values with time zone information will be converted to UTC.

Examples

```
>>> pd.read_sql_table('table_name', 'postgres:///db_name')
```

pandas.read_sql_query

```
pandas.read_sql_query(sql, con, index_col=None, coerce_float=True, params=None, parse_dates=None, chunksize=None)
```

Read SQL query into a DataFrame.

Returns a DataFrame corresponding to the result set of the query string. Optionally provide an `index_col` parameter to use one of the columns as the index, otherwise default integer index will be used.

Parameters

sql [str SQL query or SQLAlchemy Selectable (select or text object)] SQL query to be executed.

con [SQLAlchemy connectable(engine/connection), database str URI,] or sqlite3 DBAPI2 connection Using SQLAlchemy makes it possible to use any DB supported by that library. If a DBAPI2 object, only sqlite3 is supported.

index_col [str or list of strings, optional, default: None] Column(s) to set as index(MultiIndex).

coerce_float [bool, default True] Attempts to convert values of non-string, non-numeric objects (like decimal.Decimal) to floating point. Useful for SQL result sets.

params [list, tuple or dict, optional, default: None] List of parameters to pass to execute method. The syntax used to pass parameters is database driver dependent. Check your database driver documentation for which of the five syntax styles, described in PEP 249's paramstyle, is supported. Eg. for psycopg2, uses %(name)s so use params={'name': 'value'}.

parse_dates [list or dict, default: None]

- List of column names to parse as dates.
- Dict of {column_name: format_string} where format string is strftime compatible in case of parsing string times, or is one of (D, s, ns, ms, us) in case of parsing integer timestamps.
- Dict of {column_name: arg_dict}, where the arg dict corresponds to the keyword arguments of `pandas.to_datetime()`. Especially useful with databases without native Datetime support, such as SQLite.

chunksize [int, default None] If specified, return an iterator where `chunksize` is the number of rows to include in each chunk.

Returns

`DataFrame`

See also:

`read_sql_table` Read SQL database table into a DataFrame.

`read_sql`

Notes

Any datetime values with time zone information parsed via the `parse_dates` parameter will be converted to UTC.

`pandas.read_sql`

`pandas.read_sql(sql, con, index_col=None, coerce_float=True, params=None, parse_dates=None, columns=None, chunksize=None)`

Read SQL query or database table into a DataFrame.

This function is a convenience wrapper around `read_sql_table` and `read_sql_query` (for backward compatibility). It will delegate to the specific function depending on the provided input. A SQL query will be routed to `read_sql_query`, while a database table name will be routed to `read_sql_table`. Note that the delegated function might have more specific notes about their functionality not listed here.

Parameters

sql [str or SQLAlchemy Selectable (select or text object)] SQL query to be executed or a table name.

con [SQLAlchemy connectable (engine/connection) or database str URI] or DBAPI2 connection (fallback mode)

Using SQLAlchemy makes it possible to use any DB supported by that library. If a DBAPI2 object, only sqlite3 is supported. The user is responsible for engine disposal and connection closure for the SQLAlchemy connectable. See [here](#)

index_col [str or list of strings, optional, default: None] Column(s) to set as index(MultiIndex).

coerce_float [bool, default True] Attempts to convert values of non-string, non-numeric objects (like decimal.Decimal) to floating point, useful for SQL result sets.

params [list, tuple or dict, optional, default: None] List of parameters to pass to execute method. The syntax used to pass parameters is database driver dependent. Check your database driver documentation for which of the five syntax styles, described in PEP 249's

paramstyle, is supported. Eg. for psycopg2, uses %(name)s so use params={‘name’ : ‘value’}.

parse_dates [list or dict, default: None]

- List of column names to parse as dates.
- Dict of {column_name: format string} where format string is strftime compatible in case of parsing string times, or is one of (D, s, ns, ms, us) in case of parsing integer timestamps.
- Dict of {column_name: arg dict}, where the arg dict corresponds to the keyword arguments of [pandas.to_datetime\(\)](#) Especially useful with databases without native Datetime support, such as SQLite.

columns [list, default: None] List of column names to select from SQL table (only used when reading a table).

chunksize [int, default None] If specified, return an iterator where *chunksize* is the number of rows to include in each chunk.

Returns

DataFrame

See also:

[read_sql_table](#) Read SQL database table into a DataFrame.

[read_sql_query](#) Read SQL query into a DataFrame.

4.1.14 Google BigQuery

[read_gbq\(query, project_id, ...\[, ...\]\)](#)

Load data from Google BigQuery.

pandas.read_gbq

```
pandas.read_gbq(query: str, project_id: Union[str, NoneType] = None, index_col: Union[str, NoneType] = None, col_order: Union[List[str], NoneType] = None, reauth: bool = False, auth_local_webserver: bool = False, dialect: Union[str, NoneType] = None, location: Union[str, NoneType] = None, configuration: Union[Dict[str, Any], NoneType] = None, credentials=None, use_bqstorage_api: Union[bool, NoneType] = None, private_key=None, verbose=None, progress_bar_type: Union[str, NoneType] = None) → DataFrame
```

Load data from Google BigQuery.

This function requires the [pandas-gbq](#) package.

See the [How to authenticate with Google BigQuery](#) guide for authentication instructions.

Parameters

query [str] SQL-Like Query to return data values.

project_id [str, optional] Google BigQuery Account project ID. Optional when available from the environment.

index_col [str, optional] Name of result column to use for index in results DataFrame.

col_order [list(str), optional] List of BigQuery column names in the desired order for results DataFrame.

reauth [bool, default False] Force Google BigQuery to re-authenticate the user. This is useful if multiple accounts are used.

auth_local_webserver [bool, default False] Use the local webserver flow instead of the console flow when getting user credentials.

New in version 0.2.0 of pandas-gbq.

dialect [str, default ‘legacy’] Note: The default value is changing to ‘standard’ in a future version.

SQL syntax dialect to use. Value can be one of:

‘**legacy**’ Use BigQuery’s legacy SQL dialect. For more information see [BigQuery Legacy SQL Reference](#).

‘**standard**’ Use BigQuery’s standard SQL, which is compliant with the SQL 2011 standard. For more information see [BigQuery Standard SQL Reference](#).

Changed in version 0.24.0.

location [str, optional] Location where the query job should run. See the [BigQuery locations documentation](#) for a list of available locations. The location must match that of any datasets used in the query.

New in version 0.5.0 of pandas-gbq.

configuration [dict, optional] Query config parameters for job processing. For example:

```
configuration = {'query': {'useQueryCache': False}}
```

For more information see [BigQuery REST API Reference](#).

credentials [google.auth.credentials.Credentials, optional] Credentials for accessing Google APIs. Use this parameter to override default credentials, such as to use Compute Engine `google.auth.compute_engine.Credentials` or Service Account `google.oauth2.service_account.Credentials` directly.

New in version 0.8.0 of pandas-gbq.

New in version 0.24.0.

use_bqstorage_api [bool, default False] Use the [BigQuery Storage API](#) to download query results quickly, but at an increased cost. To use this API, first [enable it in the Cloud Console](#). You must also have the `bigrquery.readsessions.create` permission on the project you are billing queries to.

This feature requires version 0.10.0 or later of the `pandas-gbq` package. It also requires the `google-cloud-bigquery-storage` and `fastavro` packages.

New in version 0.25.0.

progress_bar_type [Optional, str] If set, use the `tqdm` library to display a progress bar while the data downloads. Install the `tqdm` package to use this feature.

Possible values of `progress_bar_type` include:

None No progress bar.

‘**tqdm**’ Use the `tqdm.tqdm()` function to print a progress bar to `sys.stderr`.

‘**tqdm_notebook**’ Use the `tqdm.tqdm_notebook()` function to display a progress bar as a Jupyter notebook widget.

'`tqdm_gui`' Use the `tqdm.tqdm_gui()` function to display a progress bar as a graphical dialog box.

Note that this feature requires version 0.12.0 or later of the `pandas-gbq` package. And it requires the `tqdm` package. Slightly different than `pandas-gbq`, here the default is `None`.

New in version 1.0.0.

Returns

df: DataFrame DataFrame representing results of query.

See also:

`pandas_gbq.read_gbq` This function in the `pandas-gbq` library.

`DataFrame.to_gbq` Write a DataFrame to Google BigQuery.

4.1.15 STATA

<code>read_stata(filepath_or_buffer[, ...])</code>	Read Stata file into DataFrame.
--	---------------------------------

`pandas.read_stata`

`pandas.read_stata(filepath_or_buffer, convert_dates=True, convert_categoricals=True, index_col=None, convert_missing=False, preserve_dtypes=True, columns=None, order_categoricals=True, chunksize=None, iterator=False)`

Read Stata file into DataFrame.

Parameters

filepath_or_buffer [str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file:///localhost/path/to/table.dta`.

If you want to pass in a path object, pandas accepts any `os.PathLike`.

By file-like object, we refer to objects with a `read()` method, such as a file handler (e.g. via builtin `open` function) or `StringIO`.

convert_dates [bool, default True] Convert date variables to DataFrame time values.

convert_categoricals [bool, default True] Read value labels and convert columns to Categorical/Factor variables.

index_col [str, optional] Column to set as index.

convert_missing [bool, default False] Flag indicating whether to convert missing values to their Stata representations. If False, missing values are replaced with `nan`. If True, columns containing missing values are returned with object data types and missing values are represented by `StataMissingValue` objects.

preserve_dtypes [bool, default True] Preserve Stata datatypes. If False, numeric data are upcast to pandas default types for foreign data (`float64` or `int64`).

columns [list or None] Columns to retain. Columns will be returned in the given order. `None` returns all columns.

order_categoricals [bool, default True] Flag indicating whether converted categorical data are ordered.

chunksize [int, default None] Return StataReader object for iterations, returns chunks with given number of lines.

iterator [bool, default False] Return StataReader object.

Returns

DataFrame or StataReader

See also:

io.stata.StataReader Low-level reader for Stata data files.

DataFrame.to_stata Export Stata data files.

Examples

Read a Stata dta file:

```
>>> df = pd.read_stata('filename.dta')
```

Read a Stata dta file in 10,000 line chunks:

```
>>> itr = pd.read_stata('filename.dta', chunksize=10000)
>>> for chunk in itr:
...     do_something(chunk)
```

<code>StataReader.data_label</code>	Return data label of Stata file.
<code>StataReader.value_labels(self)</code>	Return a dict, associating each variable name a dict, associating each value its corresponding label.
<code>StataReader.variable_labels(self)</code>	Return variable labels as a dict, associating each variable name with corresponding label.
<code>StataWriter.write_file(self)</code>	

pandas.io.stata.StataReader.data_label

property `StataReader.data_label`

Return data label of Stata file.

pandas.io.stata.StataReader.value_labels

`StataReader.value_labels(self)`

Return a dict, associating each variable name a dict, associating each value its corresponding label.

Returns

`dict`

`pandas.io.stata.StataReader.variable_labels`

`StataReader.variable_labels(self)`

Return variable labels as a dict, associating each variable name with corresponding label.

Returns

`dict`

`pandas.io.stata.StataWriter.write_file`

`StataWriter.write_file(self)`

`{} { header } {}`

4.2 General functions

4.2.1 Data manipulations

<code>melt(frame[, id_vars, value_vars, var_name, ...])</code>	Unpivot a DataFrame from wide to long format, optionally leaving identifiers set.
<code>pivot(data[, index, columns, values])</code>	Return reshaped DataFrame organized by given index / column values.
<code>pivot_table(data[, values, index, columns, ...])</code>	Create a spreadsheet-style pivot table as a DataFrame.
<code>crosstab(index, columns[, values, rownames, ...])</code>	Compute a simple cross tabulation of two (or more) factors.
<code>cut(x, bins, right[, labels])</code>	Bin values into discrete intervals.
<code>qcut(x, q[, labels])</code>	Quantile-based discretization function.
<code>merge(left, right, how[, on, left_on, ...])</code>	Merge DataFrame or named Series objects with a database-style join.
<code>merge_ordered(left, right[, on, left_on, ...])</code>	Perform merge with optional filling/interpolation.
<code>merge_asof(left, right[, on, left_on, ...])</code>	Perform an asof merge.
<code>concat(objs, ForwardRef)], ..., [axis, ...])</code>	Concatenate pandas objects along a particular axis with optional set logic along the other axes.
<code>get_dummies(data[, prefix, prefix_sep, ...])</code>	Convert categorical variable into dummy/indicator variables.
<code>factorize(values, sort, na_sentinel, ...)</code>	Encode the object as an enumerated type or categorical variable.
<code>unique(values)</code>	Hash table-based unique.
<code>wide_to_long(df, stubnames, i, j, sep, suffix)</code>	Wide panel to long format.

pandas.melt

`pandas.melt(frame: pandas.core.frame.DataFrame, id_vars=None, value_vars=None, var_name=None, value_name='value', col_level=None) → pandas.core.frame.DataFrame`
 Unpivot a DataFrame from wide to long format, optionally leaving identifiers set.

This function is useful to massage a DataFrame into a format where one or more columns are identifier variables (*id_vars*), while all other columns, considered measured variables (*value_vars*), are “unpivoted” to the row axis, leaving just two non-identifier columns, ‘variable’ and ‘value’.

Parameters

id_vars [tuple, list, or ndarray, optional] Column(s) to use as identifier variables.
value_vars [tuple, list, or ndarray, optional] Column(s) to unpivot. If not specified, uses all columns that are not set as *id_vars*.
var_name [scalar] Name to use for the ‘variable’ column. If None it uses `frame.columns.name` or ‘variable’.
value_name [scalar, default ‘value’] Name to use for the ‘value’ column.
col_level [int or str, optional] If columns are a MultiIndex then use this level to melt.

Returns

DataFrame Unpivoted DataFrame.

See also:

`DataFrame.melt`
`pivot_table`
`DataFrame.pivot`
`Series.explode`

Examples

```
>>> df = pd.DataFrame({'A': {0: 'a', 1: 'b', 2: 'c'},
...                     'B': {0: 1, 1: 3, 2: 5},
...                     'C': {0: 2, 1: 4, 2: 6}})
>>> df
   A  B  C
0  a  1  2
1  b  3  4
2  c  5  6
```

```
>>> pd.melt(df, id_vars=['A'], value_vars=['B'])
   A variable  value
0  a         B      1
1  b         B      3
2  c         B      5
```

```
>>> pd.melt(df, id_vars=['A'], value_vars=['B', 'C'])
   A variable  value
0  a         B      1
1  b         B      3
2  c         B      5
```

(continues on next page)

(continued from previous page)

3	a	C	2
4	b	C	4
5	c	C	6

The names of ‘variable’ and ‘value’ columns can be customized:

```
>>> pd.melt(df, id_vars=['A'], value_vars=['B'],
...           var_name='myVarname', value_name='myValname')
   A myVarname  myValname
0  a            B        1
1  b            B        3
2  c            B        5
```

If you have multi-index columns:

```
>>> df.columns = [list('ABC'), list('DEF')]
>>> df
   A  B  C
   D  E  F
0  a  1  2
1  b  3  4
2  c  5  6
```

```
>>> pd.melt(df, col_level=0, id_vars=['A'], value_vars=['B'])
   A variable  value
0  a          B    1
1  b          B    3
2  c          B    5
```

```
>>> pd.melt(df, id_vars=[('A', 'D')], value_vars=[('B', 'E')])
   (A, D)  variable_0  variable_1  value
0      a          B          E    1
1      b          B          E    3
2      c          B          E    5
```

pandas.pivot

`pandas.pivot(data: 'DataFrame', index=None, columns=None, values=None) → 'DataFrame'`

Return reshaped DataFrame organized by given index / column values.

Reshape data (produce a “pivot” table) based on column values. Uses unique values from specified `index / columns` to form axes of the resulting DataFrame. This function does not support data aggregation, multiple values will result in a MultiIndex in the columns. See the [User Guide](#) for more on reshaping.

Parameters

data [DataFrame]

index [str or object, optional] Column to use to make new frame’s index. If None, uses existing index.

columns [str or object] Column to use to make new frame’s columns.

values [str, object or a list of the previous, optional] Column(s) to use for populating new frame’s values. If not specified, all remaining columns will be used and the result will have hierarchically indexed columns.

Changed in version 0.23.0: Also accept list of column names.

Returns

DataFrame Returns reshaped DataFrame.

Raises

ValueError: When there are any *index*, *columns* combinations with multiple values.
DataFrame.pivot_table when you need to aggregate.

See also:

DataFrame.pivot_table Generalization of pivot that can handle duplicate values for one index/column pair.

DataFrame.unstack Pivot based on the index values instead of a column.

Notes

For finer-tuned control, see hierarchical indexing documentation along with the related stack/unstack methods.

Examples

```
>>> df = pd.DataFrame({'foo': ['one', 'one', 'one', 'two', 'two',
...                           'two'],
...                     'bar': ['A', 'B', 'C', 'A', 'B', 'C'],
...                     'baz': [1, 2, 3, 4, 5, 6],
...                     'zoo': ['x', 'y', 'z', 'q', 'w', 't']})
>>> df
   foo    bar  baz  zoo
0  one     A    1    x
1  one     B    2    y
2  one     C    3    z
3  two     A    4    q
4  two     B    5    w
5  two     C    6    t
```

```
>>> df.pivot(index='foo', columns='bar', values='baz')
bar  A  B  C
foo
one  1  2  3
two  4  5  6
```

```
>>> df.pivot(index='foo', columns='bar')['baz']
bar  A  B  C
foo
one  1  2  3
two  4  5  6
```

```
>>> df.pivot(index='foo', columns='bar', values=['baz', 'zoo'])
            baz      zoo
bar    A  B  C    A  B  C
foo
one  1  2  3    x  y  z
two  4  5  6    q  w  t
```

A ValueError is raised if there are any duplicates.

```
>>> df = pd.DataFrame({'foo': ['one', 'one', 'two', 'two'],
...                      'bar': ['A', 'A', 'B', 'C'],
...                      'baz': [1, 2, 3, 4]})

>>> df
   foo bar  baz
0  one    A    1
1  one    A    2
2  two    B    3
3  two    C    4
```

Notice that the first two rows are the same for our *index* and *columns* arguments.

```
>>> df.pivot(index='foo', columns='bar', values='baz')
Traceback (most recent call last):
...
ValueError: Index contains duplicate entries, cannot reshape
```

pandas.pivot_table

`pandas.pivot_table(data, values=None, index=None, columns=None, aggfunc='mean', fill_value=None, margins=False, dropna=True, margins_name='All', observed=False) → DataFrame`

Create a spreadsheet-style pivot table as a DataFrame.

The levels in the pivot table will be stored in MultiIndex objects (hierarchical indexes) on the index and columns of the result DataFrame.

Parameters

data [DataFrame]

values [column to aggregate, optional]

index [column, Grouper, array, or list of the previous] If an array is passed, it must be the same length as the data. The list can contain any of the other types (except list). Keys to group by on the pivot table index. If an array is passed, it is being used as the same manner as column values.

columns [column, Grouper, array, or list of the previous] If an array is passed, it must be the same length as the data. The list can contain any of the other types (except list). Keys to group by on the pivot table column. If an array is passed, it is being used as the same manner as column values.

aggfunc [function, list of functions, dict, default numpy.mean] If list of functions passed, the resulting pivot table will have hierarchical columns whose top level are the function names (inferred from the function objects themselves) If dict is passed, the key is column to aggregate and value is function or list of functions.

fill_value [scalar, default None] Value to replace missing values with.

margins [bool, default False] Add all row / columns (e.g. for subtotal / grand totals).

dropna [bool, default True] Do not include columns whose entries are all NaN.

margins_name [str, default 'All'] Name of the row / column that will contain the totals when margins is True.

observed [bool, default False] This only applies if any of the groupers are Categoricals. If True: only show observed values for categorical groupers. If False: show all values for categorical groupers.

Changed in version 0.25.0.

Returns

DataFrame An Excel style pivot table.

See also:

DataFrame.pivot Pivot without aggregation that can handle non-numeric data.

Examples

```
>>> df = pd.DataFrame({ "A": ["foo", "foo", "foo", "foo", "foo",
...                           "bar", "bar", "bar", "bar"],
...                     "B": ["one", "one", "one", "two", "two",
...                           "one", "one", "two", "two"],
...                     "C": ["small", "large", "large", "small",
...                           "small", "large", "small", "small",
...                           "large"],
...                     "D": [1, 2, 2, 3, 3, 4, 5, 6, 7],
...                     "E": [2, 4, 5, 6, 6, 8, 9, 9]})

>>> df
   A      B      C  D  E
0  foo    one  small  1  2
1  foo    one  large  2  4
2  foo    one  large  2  5
3  foo    two  small  3  5
4  foo    two  small  3  6
5  bar    one  large  4  6
6  bar    one  small  5  8
7  bar    two  small  6  9
8  bar    two  large  7  9
```

This first example aggregates values by taking the sum.

```
>>> table = pd.pivot_table(df, values='D', index=['A', 'B'],
...                         columns=['C'], aggfunc=np.sum)
>>> table
C      large  small
A      B
bar  one     4.0    5.0
      two     7.0    6.0
foo  one     4.0    1.0
      two     NaN    6.0
```

We can also fill missing values using the *fill_value* parameter.

```
>>> table = pd.pivot_table(df, values='D', index=['A', 'B'],
...                         columns=['C'], aggfunc=np.sum, fill_value=0)
>>> table
C      large  small
A      B
bar  one      4      5
```

(continues on next page)

(continued from previous page)

two	7	6
foo	one	1
two	0	6

The next example aggregates by taking the mean across multiple columns.

```
>>> table = pd.pivot_table(df, values=['D', 'E'], index=['A', 'C'],
...                         aggfunc={'D': np.mean,
...                                   'E': np.mean})
>>> table
          D          E
A   C
bar large  5.500000  7.500000
     small  5.500000  8.500000
foo large  2.000000  4.500000
     small  2.333333  4.333333
```

We can also calculate multiple types of aggregations for any given value column.

```
>>> table = pd.pivot_table(df, values=['D', 'E'], index=['A', 'C'],
...                         aggfunc={'D': np.mean,
...                                   'E': [min, max, np.mean]})
>>> table
          D          E
               mean  max      mean  min
A   C
bar large  5.500000  9.0  7.500000  6.0
     small  5.500000  9.0  8.500000  8.0
foo large  2.000000  5.0  4.500000  4.0
     small  2.333333  6.0  4.333333  2.0
```

pandas.crosstab

`pandas.crosstab(index, columns, values=None, rownames=None, colnames=None, aggfunc=None, margins=False, margins_name: str = 'All', dropna: bool = True, normalize=False) → DataFrame'`

Compute a simple cross tabulation of two (or more) factors. By default computes a frequency table of the factors unless an array of values and an aggregation function are passed.

Parameters

index [array-like, Series, or list of arrays/Series] Values to group by in the rows.

columns [array-like, Series, or list of arrays/Series] Values to group by in the columns.

values [array-like, optional] Array of values to aggregate according to the factors. Requires `aggfunc` be specified.

rownames [sequence, default None] If passed, must match number of row arrays passed.

colnames [sequence, default None] If passed, must match number of column arrays passed.

aggfunc [function, optional] If specified, requires `values` be specified as well.

margins [bool, default False] Add row/column margins (subtotals).

margins_name [str, default 'All'] Name of the row/column that will contain the totals when `margins` is True.

New in version 0.21.0.

dropna [bool, default True] Do not include columns whose entries are all NaN.

normalize [bool, {'all', 'index', 'columns'}, or {0,1}, default False] Normalize by dividing all values by the sum of values.

- If passed ‘all’ or *True*, will normalize over all values.
- If passed ‘index’ will normalize over each row.
- If passed ‘columns’ will normalize over each column.
- If margins is *True*, will also normalize margin values.

Returns

DataFrame Cross tabulation of the data.

See also:

`DataFrame.pivot` Reshape data based on column values.

`pivot_table` Create a pivot table as a DataFrame.

Notes

Any Series passed will have their name attributes used unless row or column names for the cross-tabulation are specified.

Any input passed containing Categorical data will have **all** of its categories included in the cross-tabulation, even if the actual data does not contain any instances of a particular category.

In the event that there aren’t overlapping indexes an empty DataFrame will be returned.

Examples

```
>>> a = np.array(["foo", "foo", "foo", "foo", "bar", "bar",
...                 "bar", "bar", "foo", "foo", "foo"], dtype=object)
>>> b = np.array(["one", "one", "one", "two", "one", "one",
...                 "one", "two", "two", "two", "one"], dtype=object)
>>> c = np.array(["dull", "dull", "shiny", "dull", "dull", "shiny",
...                 "shiny", "dull", "shiny", "shiny", "shiny"],
...                 dtype=object)
>>> pd.crosstab(a, [b, c], rownames=['a'], colnames=['b', 'c'])
b   one      two
c  dull  shiny dull shiny
a
bar    1      2    1      0
foo    2      2    1      2
```

Here ‘c’ and ‘f’ are not represented in the data and will not be shown in the output because dropna is True by default. Set dropna=False to preserve categories with no data.

```
>>> foo = pd.Categorical(['a', 'b'], categories=['a', 'b', 'c'])
>>> bar = pd.Categorical(['d', 'e'], categories=['d', 'e', 'f'])
>>> pd.crosstab(foo, bar)
col_0  d  e
row_0
```

(continues on next page)

(continued from previous page)

```
a      1  0
b      0  1
>>> pd.crosstab(foo, bar, dropna=False)
col_0  d  e  f
row_0
a      1  0  0
b      0  1  0
c      0  0  0
```

pandas.cut

`pandas.cut(x, bins, right= True, labels=None, retbins= False, precision= 3, include_lowest= False, duplicates= 'raise')`

Bin values into discrete intervals.

Use `cut` when you need to segment and sort data values into bins. This function is also useful for going from a continuous variable to a categorical variable. For example, `cut` could convert ages to groups of age ranges. Supports binning into an equal number of bins, or a pre-specified array of bins.

Parameters

x [array-like] The input array to be binned. Must be 1-dimensional.

bins [int, sequence of scalars, or IntervalIndex] The criteria to bin by.

- int : Defines the number of equal-width bins in the range of *x*. The range of *x* is extended by .1% on each side to include the minimum and maximum values of *x*.
- sequence of scalars : Defines the bin edges allowing for non-uniform width. No extension of the range of *x* is done.
- IntervalIndex : Defines the exact bins to be used. Note that IntervalIndex for *bins* must be non-overlapping.

right [bool, default True] Indicates whether *bins* includes the rightmost edge or not. If `right == True` (the default), then the *bins* [1, 2, 3, 4] indicate (1,2], (2,3], (3,4]. This argument is ignored when *bins* is an IntervalIndex.

labels [array or False, default None] Specifies the labels for the returned bins. Must be the same length as the resulting bins. If False, returns only integer indicators of the bins. This affects the type of the output container (see below). This argument is ignored when *bins* is an IntervalIndex. If True, raises an error.

retbins [bool, default False] Whether to return the bins or not. Useful when *bins* is provided as a scalar.

precision [int, default 3] The precision at which to store and display the bins labels.

include_lowest [bool, default False] Whether the first interval should be left-inclusive or not.

duplicates [{default ‘raise’, ‘drop’}, optional] If bin edges are not unique, raise ValueError or drop non-uniques.

New in version 0.23.0.

Returns

out [Categorical, Series, or ndarray] An array-like object representing the respective bin for each value of *x*. The type depends on the value of *labels*.

- True (default) : returns a Series for Series x or a Categorical for all other inputs. The values stored within are Interval dtype.
- sequence of scalars : returns a Series for Series x or a Categorical for all other inputs. The values stored within are whatever the type in the sequence is.
- False : returns an ndarray of integers.

bins [numpy.ndarray or IntervalIndex.] The computed or specified bins. Only returned when `retbins=True`. For scalar or sequence $bins$, this is an ndarray with the computed bins. If set `duplicates=drop`, $bins$ will drop non-unique bin. For an IntervalIndex $bins$, this is equal to $bins$.

See also:

[`qcut`](#) Discretize variable into equal-sized buckets based on rank or based on sample quantiles.

[`Categorical`](#) Array type for storing data that come from a fixed set of values.

[`Series`](#) One-dimensional array with axis labels (including time series).

[`IntervalIndex`](#) Immutable Index implementing an ordered, sliceable set.

Notes

Any NA values will be NA in the result. Out of bounds values will be NA in the resulting Series or Categorical object.

Examples

Discretize into three equal-sized bins.

```
>>> pd.cut(np.array([1, 7, 5, 4, 6, 3]), 3)
...
[(0.994, 3.0], (5.0, 7.0], (3.0, 5.0], (3.0, 5.0], (5.0, 7.0], ...
Categories (3, interval[float64]): [(0.994, 3.0] < (3.0, 5.0] ...]
```

```
>>> pd.cut(np.array([1, 7, 5, 4, 6, 3]), 3, retbins=True)
...
([(0.994, 3.0], (5.0, 7.0], (3.0, 5.0], (3.0, 5.0], (5.0, 7.0], ...
Categories (3, interval[float64]): [(0.994, 3.0] < (3.0, 5.0] ...
array([0.994, 3.    , 5.    , 7.    ]))
```

Discovers the same bins, but assign them specific labels. Notice that the returned Categorical's categories are *labels* and is ordered.

```
>>> pd.cut(np.array([1, 7, 5, 4, 6, 3]),
...         3, labels=["bad", "medium", "good"])
[bad, good, medium, medium, good, bad]
Categories (3, object): [bad < medium < good]
```

`labels=False` implies you just want the bins back.

```
>>> pd.cut([0, 1, 1, 2], bins=4, labels=False)
array([0, 1, 1, 3])
```

Passing a Series as an input returns a Series with categorical dtype:

```
>>> s = pd.Series(np.array([2, 4, 6, 8, 10]),
...                 index=['a', 'b', 'c', 'd', 'e'])
>>> pd.cut(s, 3)
...
a    (1.992, 4.667]
b    (1.992, 4.667]
c    (4.667, 7.333]
d    (7.333, 10.0]
e    (7.333, 10.0]
dtype: category
Categories (3, interval[float64]): [(1.992, 4.667] < (4.667, ...]
```

Passing a Series as an input returns a Series with mapping value. It is used to map numerically to intervals based on bins.

```
>>> s = pd.Series(np.array([2, 4, 6, 8, 10]),
...                 index=['a', 'b', 'c', 'd', 'e'])
>>> pd.cut(s, [0, 2, 4, 6, 8, 10], labels=False, retbins=True, right=False)
...
(a    0.0
 b    1.0
 c    2.0
 d    3.0
 e    4.0
dtype: float64, array([0, 2, 4, 6, 8]))
```

Use *drop* optional when bins is not unique

```
>>> pd.cut(s, [0, 2, 4, 6, 10, 10], labels=False, retbins=True,
...           right=False, duplicates='drop')
...
(a    0.0
 b    1.0
 c    2.0
 d    3.0
 e    3.0
dtype: float64, array([0, 2, 4, 6, 8]))
```

Passing an IntervalIndex for *bins* results in those categories exactly. Notice that values not covered by the IntervalIndex are set to NaN. 0 is to the left of the first bin (which is closed on the right), and 1.5 falls between two bins.

```
>>> bins = pd.IntervalIndex.from_tuples([(0, 1), (2, 3), (4, 5)])
>>> pd.cut([0, 0.5, 1.5, 2.5, 4.5], bins)
[NaN, (0, 1], NaN, (2, 3], (4, 5]]
Categories (3, interval[int64]): [(0, 1] < (2, 3] < (4, 5]]
```

pandas.qcut

```
pandas.qcut(x, q, labels=None, retbins=False, precision=3, duplicates='raise')
```

Quantile-based discretization function.

Discretize variable into equal-sized buckets based on rank or based on sample quantiles. For example 1000 values for 10 quantiles would produce a Categorical object indicating quantile membership for each data point.

Parameters

x [1d ndarray or Series]

q [int or list-like of int] Number of quantiles. 10 for deciles, 4 for quartiles, etc. Alternately array of quantiles, e.g. [0, .25, .5, .75, 1.] for quartiles.

labels [array or False, default None] Used as labels for the resulting bins. Must be of the same length as the resulting bins. If False, return only integer indicators of the bins. If True, raises an error.

retbins [bool, optional] Whether to return the (bins, labels) or not. Can be useful if bins is given as a scalar.

precision [int, optional] The precision at which to store and display the bins labels.

duplicates [{default ‘raise’, ‘drop’}, optional] If bin edges are not unique, raise ValueError or drop non-uniques.

Returns

out [Categorical or Series or array of integers if labels is False] The return type (Categorical or Series) depends on the input: a Series of type category if input is a Series else Categorical. Bins are represented as categories when categorical data is returned.

bins [ndarray of floats] Returned only if *retbins* is True.

Notes

Out of bounds values will be NA in the resulting Categorical object

Examples

```
>>> pd.qcut(range(5), 4)
...
[(-0.001, 1.0], (-0.001, 1.0], (1.0, 2.0], (2.0, 3.0], (3.0, 4.0]]
Categories (4, interval[float64]): [(-0.001, 1.0] < (1.0, 2.0] ...]
```

```
>>> pd.qcut(range(5), 3, labels=["good", "medium", "bad"])
...
[good, good, medium, bad, bad]
Categories (3, object): [good < medium < bad]
```

```
>>> pd.qcut(range(5), 4, labels=False)
array([0, 0, 1, 2, 3])
```

pandas.merge

```
pandas.merge(left, right, how: str = 'inner', on=None, left_on=None, right_on=None, left_index: bool = False, right_index: bool = False, sort: bool = False, suffixes=('_x', '_y'), copy: bool = True, indicator: bool = False, validate=None) → DataFrame
```

Merge DataFrame or named Series objects with a database-style join.

The join is done on columns or indexes. If joining columns on columns, the DataFrame indexes *will be ignored*. Otherwise if joining indexes on indexes or indexes on a column or columns, the index will be passed on.

Parameters

left [DataFrame]

right [DataFrame or named Series] Object to merge with.

how [{‘left’, ‘right’, ‘outer’, ‘inner’}, default ‘inner’] Type of merge to be performed.

- left: use only keys from left frame, similar to a SQL left outer join; preserve key order.
- right: use only keys from right frame, similar to a SQL right outer join; preserve key order.
- outer: use union of keys from both frames, similar to a SQL full outer join; sort keys lexicographically.
- inner: use intersection of keys from both frames, similar to a SQL inner join; preserve the order of the left keys.

on [label or list] Column or index level names to join on. These must be found in both DataFrames. If *on* is None and not merging on indexes then this defaults to the intersection of the columns in both DataFrames.

left_on [label or list, or array-like] Column or index level names to join on in the left DataFrame. Can also be an array or list of arrays of the length of the left DataFrame. These arrays are treated as if they are columns.

right_on [label or list, or array-like] Column or index level names to join on in the right DataFrame. Can also be an array or list of arrays of the length of the right DataFrame. These arrays are treated as if they are columns.

left_index [bool, default False] Use the index from the left DataFrame as the join key(s). If it is a MultiIndex, the number of keys in the other DataFrame (either the index or a number of columns) must match the number of levels.

right_index [bool, default False] Use the index from the right DataFrame as the join key. Same caveats as *left_index*.

sort [bool, default False] Sort the join keys lexicographically in the result DataFrame. If False, the order of the join keys depends on the join type (how keyword).

suffixes [tuple of (str, str), default (‘_x’, ‘_y’)] Suffix to apply to overlapping column names in the left and right side, respectively. To raise an exception on overlapping columns use (False, False).

copy [bool, default True] If False, avoid copy if possible.

indicator [bool or str, default False] If True, adds a column to output DataFrame called “_merge” with information on the source of each row. If string, column with information on source of each row will be added to output DataFrame, and column will be named value of string. Information column is Categorical-type and takes on a value of “left_only” for observations whose merge key only appears in ‘left’ DataFrame, “right_only” for observations

whose merge key only appears in ‘right’ DataFrame, and “both” if the observation’s merge key is found in both.

validate [str, optional] If specified, checks if merge is of specified type.

- “one_to_one” or “1:1”: check if merge keys are unique in both left and right datasets.
- “one_to_many” or “1:m”: check if merge keys are unique in left dataset.
- “many_to_one” or “m:1”: check if merge keys are unique in right dataset.
- “many_to_many” or “m:m”: allowed, but does not result in checks.

New in version 0.21.0.

Returns

DataFrame A DataFrame of the two merged objects.

See also:

[**merge_ordered**](#) Merge with optional filling/interpolation.

[**merge_asof**](#) Merge on nearest keys.

[**DataFrame.join**](#) Similar method using indices.

Notes

Support for specifying index levels as the *on*, *left_on*, and *right_on* parameters was added in version 0.23.0
Support for merging named Series objects was added in version 0.24.0

Examples

```
>>> df1 = pd.DataFrame({'lkey': ['foo', 'bar', 'baz', 'foo'],
...                      'value': [1, 2, 3, 5]})
>>> df2 = pd.DataFrame({'rkey': ['foo', 'bar', 'baz', 'foo'],
...                      'value': [5, 6, 7, 8]})
>>> df1
   lkey  value
0  foo      1
1  bar      2
2  baz      3
3  foo      5
>>> df2
   rkey  value
0  foo      5
1  bar      6
2  baz      7
3  foo      8
```

Merge df1 and df2 on the lkey and rkey columns. The value columns have the default suffixes, _x and _y, appended.

```
>>> df1.merge(df2, left_on='lkey', right_on='rkey')
   lkey  value_x  rkey  value_y
0  foo        1  foo        5
1  foo        1  foo        8
2  foo        5  foo        5
```

(continues on next page)

(continued from previous page)

3	foo	5	foo	8
4	bar	2	bar	6
5	baz	3	baz	7

Merge DataFrames df1 and df2 with specified left and right suffixes appended to any overlapping columns.

```
>>> df1.merge(df2, left_on='lkey', right_on='rkey',
...             suffixes=('_left', '_right'))
   lkey  value_left rkey  value_right
0  foo            1  foo            5
1  foo            1  foo            8
2  foo            5  foo            5
3  foo            5  foo            8
4  bar            2  bar            6
5  baz            3  baz            7
```

Merge DataFrames df1 and df2, but raise an exception if the DataFrames have any overlapping columns.

```
>>> df1.merge(df2, left_on='lkey', right_on='rkey', suffixes=(False, False))
Traceback (most recent call last):
...
ValueError: columns overlap but no suffix specified:
Index(['value'], dtype='object')
```

pandas.merge_ordered

pandas.**merge_ordered**(*left*, *right*, *on=None*, *left_on=None*, *right_on=None*, *left_by=None*, *right_by=None*, *fill_method=None*, *suffixes=('_x', '_y')*, *how: str = 'outer'*) → DataFrame

Perform merge with optional filling/interpolation.

Designed for ordered data like time series data. Optionally perform group-wise merge (see examples).

Parameters

left [DataFrame]

right [DataFrame]

on [label or list] Field names to join on. Must be found in both DataFrames.

left_on [label or list, or array-like] Field names to join on in left DataFrame. Can be a vector or list of vectors of the length of the DataFrame to use a particular vector as the join key instead of columns.

right_on [label or list, or array-like] Field names to join on in right DataFrame or vector/list of vectors per *left_on* docs.

left_by [column name or list of column names] Group left DataFrame by group columns and merge piece by piece with right DataFrame.

right_by [column name or list of column names] Group right DataFrame by group columns and merge piece by piece with left DataFrame.

fill_method [{‘ffill’}, None], default None] Interpolation method for data.

suffixes [Sequence, default is (“_x”, “_y”)] A length-2 sequence where each element is optionally a string indicating the suffix to add to overlapping column names in *left* and *right*

respectively. Pass a value of *None* instead of a string to indicate that the column name from *left* or *right* should be left as-is, with no suffix. At least one of the values must not be *None*.

Changed in version 0.25.0.

how [{‘left’, ‘right’, ‘outer’, ‘inner’}], default ‘outer’]

- *left*: use only keys from left frame (SQL: left outer join)
- *right*: use only keys from right frame (SQL: right outer join)
- *outer*: use union of keys from both frames (SQL: full outer join)
- *inner*: use intersection of keys from both frames (SQL: inner join).

Returns

DataFrame The merged DataFrame output type will be same as ‘left’, if it is a subclass of DataFrame.

[merge_asof](#)

Examples

```
>>> A
      key  lvalue group
0     a      1     a
1     c      2     a
2     e      3     a
3     a      1     b
4     c      2     b
5     e      3     b
```

```
>>> B
      Key  rvalue
0     b      1
1     c      2
2     d      3
```

```
>>> merge_ordered(A, B, fill_method='ffill', left_by='group')
      group key  lvalue  rvalue
0       a   a      1    NaN
1       a   b      1    1.0
2       a   c      2    2.0
3       a   d      2    3.0
4       a   e      3    3.0
5       b   a      1    NaN
6       b   b      1    1.0
7       b   c      2    2.0
8       b   d      2    3.0
9       b   e      3    3.0
```

`pandas.merge_asof`

```
pandas.merge_asof(left, right, on=None, left_on=None, right_on=None, left_index: bool = False,  
                  right_index: bool = False, by=None, left_by=None, right_by=None, suffixes=('_x',  
                  '_y'), tolerance=None, allow_exact_matches: bool = True, direction: str = 'back-  
                  ward') → DataFrame
```

Perform an asof merge. This is similar to a left-join except that we match on nearest key rather than equal keys.

Both DataFrames must be sorted by the key.

For each row in the left DataFrame:

- A “backward” search selects the last row in the right DataFrame whose ‘on’ key is less than or equal to the left’s key.
- A “forward” search selects the first row in the right DataFrame whose ‘on’ key is greater than or equal to the left’s key.
- A “nearest” search selects the row in the right DataFrame whose ‘on’ key is closest in absolute distance to the left’s key.

The default is “backward” and is compatible in versions below 0.20.0. The direction parameter was added in version 0.20.0 and introduces “forward” and “nearest”.

Optionally match on equivalent keys with ‘by’ before searching with ‘on’.

Parameters

left [DataFrame]

right [DataFrame]

on [label] Field name to join on. Must be found in both DataFrames. The data MUST be ordered. Furthermore this must be a numeric column, such as datetimelike, integer, or float. On or left_on/right_on must be given.

left_on [label] Field name to join on in left DataFrame.

right_on [label] Field name to join on in right DataFrame.

left_index [bool] Use the index of the left DataFrame as the join key.

right_index [bool] Use the index of the right DataFrame as the join key.

by [column name or list of column names] Match on these columns before performing merge operation.

left_by [column name] Field names to match on in the left DataFrame.

right_by [column name] Field names to match on in the right DataFrame.

suffixes [2-length sequence (tuple, list, …)] Suffix to apply to overlapping column names in the left and right side, respectively.

tolerance [int or Timedelta, optional, default None] Select asof tolerance within this range; must be compatible with the merge index.

allow_exact_matches [bool, default True]

- If True, allow matching with the same ‘on’ value (i.e. less-than-or-equal-to / greater-than-or-equal-to)
- If False, don’t match the same ‘on’ value (i.e., strictly less-than / strictly greater-than).

direction ['backward' (default), 'forward', or 'nearest'] Whether to search for prior, subsequent, or closest matches.

Returns

merged [DataFrame]

[merge](#)

[merge_ordered](#)

Examples

```
>>> left = pd.DataFrame({'a': [1, 5, 10], 'left_val': ['a', 'b', 'c']})
>>> left
   a  left_val
0  1        a
1  5        b
2 10        c
```

```
>>> right = pd.DataFrame({'a': [1, 2, 3, 6, 7],
...                         'right_val': [1, 2, 3, 6, 7]})
>>> right
   a  right_val
0  1          1
1  2          2
2  3          3
3  6          6
4  7          7
```

```
>>> pd.merge_asof(left, right, on='a')
      a  left_val  right_val
0    1        a        1
1    5        b        3
2   10        c        7
```

```
>>> pd.merge_asof(left, right, on='a', allow_exact_matches=False)
      a  left_val  right_val
0    1        a       NaN
1    5        b      3.0
2   10        c      7.0
```

```
>>> pd.merge_asof(left, right, on='a', direction='forward')
      a  left_val  right_val
0    1        a      1.0
1    5        b      6.0
2   10        c     NaN
```

```
>>> pd.merge_asof(left, right, on='a', direction='nearest')
      a  left_val  right_val
0    1        a        1
1    5        b        6
2   10        c        7
```

We can use indexed DataFrames as well.

```
>>> left = pd.DataFrame({'left_val': ['a', 'b', 'c']}, index=[1, 5, 10])
>>> left
   left_val
1          a
5          b
10         c
```

```
>>> right = pd.DataFrame({'right_val': [1, 2, 3, 6, 7]}, index=[1, 2, 3, 6, 7])
...
>>> right
   right_val
1          1
2          2
3          3
6          6
7          7
```

```
>>> pd.merge_asof(left, right, left_index=True, right_index=True)
      left_val  right_val
1          a          1
5          b          3
10         c          7
```

Here is a real-world times-series example

```
>>> quotes
           time ticker    bid    ask
0 2016-05-25 13:30:00.023  GOOG  720.50  720.93
1 2016-05-25 13:30:00.023  MSFT  51.95  51.96
2 2016-05-25 13:30:00.030  MSFT  51.97  51.98
3 2016-05-25 13:30:00.041  MSFT  51.99  52.00
4 2016-05-25 13:30:00.048  GOOG  720.50  720.93
5 2016-05-25 13:30:00.049  AAPL  97.99  98.01
6 2016-05-25 13:30:00.072  GOOG  720.50  720.88
7 2016-05-25 13:30:00.075  MSFT  52.01  52.03
```

```
>>> trades
           time ticker  price  quantity
0 2016-05-25 13:30:00.023  MSFT    51.95        75
1 2016-05-25 13:30:00.038  MSFT    51.95       155
2 2016-05-25 13:30:00.048  GOOG    720.77       100
3 2016-05-25 13:30:00.048  GOOG    720.92       100
4 2016-05-25 13:30:00.048  AAPL    98.00       100
```

By default we are taking the asof of the quotes

```
>>> pd.merge_asof(trades, quotes,
...                  on='time',
...                  by='ticker')
           time ticker  price  quantity    bid    ask
0 2016-05-25 13:30:00.023  MSFT    51.95        75  51.95  51.96
1 2016-05-25 13:30:00.038  MSFT    51.95       155  51.97  51.98
2 2016-05-25 13:30:00.048  GOOG    720.77       100  720.50  720.93
3 2016-05-25 13:30:00.048  GOOG    720.92       100  720.50  720.93
4 2016-05-25 13:30:00.048  AAPL    98.00       100      NaN     NaN
```

We only asof within 2ms between the quote time and the trade time

```
>>> pd.merge_asof(trades, quotes,
...                  on='time',
...                  by='ticker',
...                  tolerance=pd.Timedelta('2ms'))
   time ticker  price  quantity     bid     ask
0 2016-05-25 13:30:00.023    MSFT  51.95      75  51.95  51.96

pandas.concat

`pandas.concat(objs: Union[Iterable[Union[ForwardRef['DataFrame'], ForwardRef['Series']]], Mapping[Union[Hashable, NoneType], Union[ForwardRef['DataFrame'], ForwardRef['Series']]]], axis=0, join='outer', ignore_index: bool = False, keys=None, levels=None, names=None, verify_integrity: bool = False, sort: bool = False, copy: bool = True) → Union[ForwardRef['DataFrame'], ForwardRef['Series']]`

Concatenate pandas objects along a particular axis with optional set logic along the other axes.

Can also add a layer of hierarchical indexing on the concatenation axis, which may be useful if the labels are the same (or overlapping) on the passed axis number.

Parameters

objs [a sequence or mapping of Series or DataFrame objects] If a dict is passed, the sorted keys will be used as the `keys` argument, unless it is passed, in which case the values will be selected (see below). Any None objects will be dropped silently unless they are all None in which case a ValueError will be raised.

axis [{0/'index', 1/'columns'}, default 0] The axis to concatenate along.

join [{‘inner’, ‘outer’}, default ‘outer’] How to handle indexes on other axis (or axes).

ignore_index [bool, default False] If True, do not use the index values along the concatenation axis. The resulting axis will be labeled 0, …, n - 1. This is useful if you are concatenating objects where the concatenation axis does not have meaningful indexing information. Note the index values on the other axes are still respected in the join.

keys [sequence, default None] If multiple levels passed, should contain tuples. Construct hierarchical index using the passed keys as the outermost level.

levels [list of sequences, default None] Specific levels (unique values) to use for constructing a MultiIndex. Otherwise they will be inferred from the keys.

names [list, default None] Names for the levels in the resulting hierarchical index.

verify_integrity [bool, default False] Check whether the new concatenated axis contains duplicates. This can be very expensive relative to the actual data concatenation.

sort [bool, default False] Sort non-concatenation axis if it is not already aligned when *join* is ‘outer’. This has no effect when *join*=‘inner’, which already preserves the order of the non-concatenation axis.

New in version 0.23.0.

Changed in version 1.0.0: Changed to not sort by default.

copy [bool, default True] If False, do not copy data unnecessarily.

Returns

object, type of objs When concatenating all Series along the index (axis=0), a Series is returned. When objs contains at least one DataFrame, a DataFrame is returned. When concatenating along the columns (axis=1), a DataFrame is returned.

See also:

[`Series.append`](#) Concatenate Series.

[`DataFrame.append`](#) Concatenate DataFrames.

[`DataFrame.join`](#) Join DataFrames using indexes.

[`DataFrame.merge`](#) Merge DataFrames by indexes or columns.

Notes

The keys, levels, and names arguments are all optional.

A walkthrough of how this method fits in with other tools for combining pandas objects can be found [here](#).

Examples

Combine two Series.

```
>>> s1 = pd.Series(['a', 'b'])
>>> s2 = pd.Series(['c', 'd'])
>>> pd.concat([s1, s2])
0    a
1    b
0    c
1    d
dtype: object
```

Clear the existing index and reset it in the result by setting the `ignore_index` option to True.

```
>>> pd.concat([s1, s2], ignore_index=True)
0    a
1    b
2    c
```

(continues on next page)

(continued from previous page)

```
3    d
dtype: object
```

Add a hierarchical index at the outermost level of the data with the `keys` option.

```
>>> pd.concat([s1, s2], keys=['s1', 's2'])
s1   0      a
      1      b
s2   0      c
      1      d
dtype: object
```

Label the index keys you create with the `names` option.

```
>>> pd.concat([s1, s2], keys=['s1', 's2'],
...             names=['Series name', 'Row ID'])
Series name  Row ID
s1            0      a
                1      b
s2            0      c
                1      d
dtype: object
```

Combine two DataFrame objects with identical columns.

```
>>> df1 = pd.DataFrame([[['a', 1], ['b', 2]],
...                      columns=['letter', 'number']])
>>> df1
   letter  number
0      a      1
1      b      2
>>> df2 = pd.DataFrame([[['c', 3], ['d', 4]],
...                      columns=['letter', 'number']])
>>> df2
   letter  number
0      c      3
1      d      4
>>> pd.concat([df1, df2])
   letter  number
0      a      1
1      b      2
0      c      3
1      d      4
```

Combine DataFrame objects with overlapping columns and return everything. Columns outside the intersection will be filled with NaN values.

```
>>> df3 = pd.DataFrame([[['c', 3, 'cat'], ['d', 4, 'dog']],
...                      columns=['letter', 'number', 'animal']])
>>> df3
   letter  number  animal
0      c      3    cat
1      d      4    dog
>>> pd.concat([df1, df3], sort=False)
   letter  number  animal
0      a      1    NaN
```

(continues on next page)

(continued from previous page)

1	b	2	NaN
0	c	3	cat
1	d	4	dog

Combine DataFrame objects with overlapping columns and return only those that are shared by passing `inner` to the `join` keyword argument.

```
>>> pd.concat([df1, df3], join="inner")
   letter  number
0        a      1
1        b      2
0        c      3
1        d      4
```

Combine DataFrame objects horizontally along the x axis by passing `in axis=1`.

```
>>> df4 = pd.DataFrame([['bird', 'polly'], ['monkey', 'george']],
...                      columns=['animal', 'name'])
>>> pd.concat([df1, df4], axis=1)
   letter  number  animal    name
0        a      1    bird  polly
1        b      2  monkey  george
```

Prevent the result from including duplicate index values with the `verify_integrity` option.

```
>>> df5 = pd.DataFrame([1], index=['a'])
>>> df5
   0
a  1
>>> df6 = pd.DataFrame([2], index=['a'])
>>> df6
   0
a  2
>>> pd.concat([df5, df6], verify_integrity=True)
Traceback (most recent call last):
...
ValueError: Indexes have overlapping values: ['a']
```

pandas.get_dummies

`pandas.get_dummies(data, prefix=None, prefix_sep='_', dummy_na=False, columns=None, sparse=False, drop_first=False, dtype=None) → 'DataFrame'`
Convert categorical variable into dummy/indicator variables.

Parameters

data [array-like, Series, or DataFrame] Data of which to get dummy indicators.

prefix [str, list of str, or dict of str, default None] String to append DataFrame column names.
Pass a list with length equal to the number of columns when calling `get_dummies` on a DataFrame. Alternatively, `prefix` can be a dictionary mapping column names to prefixes.

prefix_sep [str, default '_'] If appending prefix, separator/delimiter to use. Or pass a list or dictionary as with `prefix`.

dummy_na [bool, default False] Add a column to indicate NaNs, if False NaNs are ignored.

columns [list-like, default None] Column names in the DataFrame to be encoded. If *columns* is None then all the columns with *object* or *category* dtype will be converted.

sparse [bool, default False] Whether the dummy-encoded columns should be backed by a SparseArray (True) or a regular NumPy array (False).

drop_first [bool, default False] Whether to get k-1 dummies out of k categorical levels by removing the first level.

dtype [dtype, default np.uint8] Data type for new columns. Only a single dtype is allowed.

New in version 0.23.0.

Returns

DataFrame Dummy-coded data.

See also:

`Series.str.get_dummies` Convert Series to dummy codes.

Examples

```
>>> s = pd.Series(list('abca'))
```

```
>>> pd.get_dummies(s)
   a   b   c
0  1   0   0
1  0   1   0
2  0   0   1
3  1   0   0
```

```
>>> s1 = ['a', 'b', np.nan]
```

```
>>> pd.get_dummies(s1)
   a   b
0  1   0
1  0   1
2  0   0
```

```
>>> pd.get_dummies(s1, dummy_na=True)
   a   b   NaN
0  1   0     0
1  0   1     0
2  0   0     1
```

```
>>> df = pd.DataFrame({'A': ['a', 'b', 'a'], 'B': ['b', 'a', 'c'],
...                      'C': [1, 2, 3]})
```

```
>>> pd.get_dummies(df, prefix=['col1', 'col2'])
      C  col1_a  col1_b  col2_a  col2_b  col2_c
0    1        1        0        0        1        0
1    2        0        1        1        0        0
2    3        1        0        0        0        1
```

```
>>> pd.get_dummies(pd.Series(list('abcaa')))

   a   b   c
0  1   0   0
1  0   1   0
2  0   0   1
3  1   0   0
4  1   0   0
```

```
>>> pd.get_dummies(pd.Series(list('abcaa'))), drop_first=True)

   b   c
0  0   0
1  1   0
2  0   1
3  0   0
4  0   0
```

```
>>> pd.get_dummies(pd.Series(list('abc'))), dtype=float)

      a      b      c
0  1.0  0.0  0.0
1  0.0  1.0  0.0
2  0.0  0.0  1.0
```

pandas.factorize

```
pandas.factorize(values, sort: bool = False, na_sentinel: int = -1, size_hint: Union[int, NoneType] = None) → Tuple[numpy.ndarray, Union[numpy.ndarray, pandas.core.dtypes.generic ABCIndex]]
```

Encode the object as an enumerated type or categorical variable.

This method is useful for obtaining a numeric representation of an array when all that matters is identifying distinct values. `factorize` is available as both a top-level function `pandas.factorize()`, and as a method `Series.factorize()` and `Index.factorize()`.

Parameters

values [sequence] A 1-D sequence. Sequences that aren't pandas objects are coerced to ndarrays before factorization.

sort [bool, default False] Sort *uniques* and shuffle *codes* to maintain the relationship.

na_sentinel [int, default -1] Value to mark “not found”.

size_hint [int, optional] Hint to the hashtable sizer.

Returns

codes [ndarray] An integer ndarray that's an indexer into *uniques*. *uniques.take(codes)* will have the same values as *values*.

uniques [ndarray, Index, or Categorical] The unique valid values. When *values* is Categorical, *uniques* is a Categorical. When *values* is some other pandas object, an *Index* is returned. Otherwise, a 1-D ndarray is returned.

Note: Even if there's a missing value in *values*, *uniques* will not contain an entry for it.

See also:

`cut` Discretize continuous-valued array.

`unique` Find the unique value in an array.

Examples

These examples all show factorize as a top-level method like `pd.factorize(values)`. The results are identical for methods like `Series.factorize()`.

```
>>> codes, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'])
>>> codes
array([0, 0, 1, 2, 0])
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

With `sort=True`, the `uniques` will be sorted, and `codes` will be shuffled so that the relationship is maintained.

```
>>> codes, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'], sort=True)
>>> codes
array([1, 1, 0, 2, 1])
>>> uniques
array(['a', 'b', 'c'], dtype=object)
```

Missing values are indicated in `codes` with `na_sentinel` (-1 by default). Note that missing values are never included in `uniques`.

```
>>> codes, uniques = pd.factorize(['b', None, 'a', 'c', 'b'])
>>> codes
array([ 0, -1,  1,  2,  0])
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

Thus far, we've only factorized lists (which are internally coerced to NumPy arrays). When factorizing pandas objects, the type of `uniques` will differ. For Categoricals, a *Categorical* is returned.

```
>>> cat = pd.Categorical(['a', 'a', 'c'], categories=['a', 'b', 'c'])
>>> codes, uniques = pd.factorize(cat)
>>> codes
array([0, 0, 1])
>>> uniques
[a, c]
Categories (3, object): [a, b, c]
```

Notice that 'b' is in `uniques.categories`, despite not being present in `cat.values`.

For all other pandas objects, an Index of the appropriate type is returned.

```
>>> cat = pd.Series(['a', 'a', 'c'])
>>> codes, uniques = pd.factorize(cat)
>>> codes
array([0, 0, 1])
>>> uniques
Index(['a', 'c'], dtype='object')
```

pandas.unique

`pandas.unique(values)`

Hash table-based unique. Uniques are returned in order of appearance. This does NOT sort.

Significantly faster than numpy.unique. Includes NA values.

Parameters

`values` [1d array-like]

Returns

`numpy.ndarray` or `ExtensionArray` The return can be:

- Index : when the input is an Index
- Categorical : when the input is a Categorical dtype
- ndarray : when the input is a Series/ndarray

Return numpy.ndarray or ExtensionArray.

See also:

[`Index.unique`](#)

[`Series.unique`](#)

Examples

```
>>> pd.unique(pd.Series([2, 1, 3, 3]))  
array([2, 1, 3])
```

```
>>> pd.unique(pd.Series([2] + [1] * 5))  
array([2, 1])
```

```
>>> pd.unique(pd.Series([pd.Timestamp('20160101'),  
...                      pd.Timestamp('20160101')])))  
array(['2016-01-01T00:00:00.000000000'], dtype='datetime64[ns]')
```

```
>>> pd.unique(pd.Series([pd.Timestamp('20160101', tz='US/Eastern'),  
...                      pd.Timestamp('20160101', tz='US/Eastern')])))  
array([Timestamp('2016-01-01 00:00:00-0500', tz='US/Eastern')],  
      dtype=object)
```

```
>>> pd.unique(pd.Index([pd.Timestamp('20160101', tz='US/Eastern'),  
...                      pd.Timestamp('20160101', tz='US/Eastern')])))  
DatetimeIndex(['2016-01-01 00:00:00-05:00'],  
              dtype='datetime64[ns, US/Eastern]', freq=None)
```

```
>>> pd.unique(list('baabc'))  
array(['b', 'a', 'c'], dtype=object)
```

An unordered Categorical will return categories in the order of appearance.

```
>>> pd.unique(pd.Series(pd.Categorical(list('baabc'))))  
[b, a, c]  
Categories (3, object): [b, a, c]
```

```
>>> pd.unique(pd.Series(pd.Categorical(list('baabc'),
...                                         categories=list('abc'))))
[b, a, c]
Categories (3, object): [b, a, c]
```

An ordered Categorical preserves the category ordering.

```
>>> pd.unique(pd.Series(pd.Categorical(list('baabc'),
...                                         categories=list('abc'),
...                                         ordered=True)))
[b, a, c]
Categories (3, object): [a < b < c]
```

An array of tuples

```
>>> pd.unique([(('a', 'b'), ('b', 'a'), ('a', 'c'), ('b', 'a')),
...             ('a', 'b'), ('b', 'a'), ('a', 'c')], dtype=object)
array([(('a', 'b'), ('b', 'a'), ('a', 'c')),
```

pandas.wide_to_long

`pandas.wide_to_long(df: pandas.core.frame.DataFrame, stubnames, i, j, sep: str = "", suffix: str = '\d+') → pandas.core.frame.DataFrame`

Wide panel to long format. Less flexible but more user-friendly than melt.

With stubnames ['A', 'B'], this function expects to find one or more group of columns with format A-suffix1, A-suffix2,..., B-suffix1, B-suffix2,... You specify what you want to call this suffix in the resulting long format with *j* (for example *j*=*'year'*)

Each row of these wide variables are assumed to be uniquely identified by *i* (can be a single column name or a list of column names)

All remaining variables in the data frame are left intact.

Parameters

df [DataFrame] The wide-format DataFrame.

stubnames [str or list-like] The stub name(s). The wide format variables are assumed to start with the stub names.

i [str or list-like] Column(s) to use as id variable(s).

j [str] The name of the sub-observation variable. What you wish to name your suffix in the long format.

sep [str, default ""] A character indicating the separation of the variable names in the wide format, to be stripped from the names in the long format. For example, if your column names are A-suffix1, A-suffix2, you can strip the hyphen by specifying *sep*= '-'.

suffix [str, default '\d+'] A regular expression capturing the wanted suffixes. '\d+' captures numeric suffixes. Suffixes with no numbers could be specified with the negated character class '\D+'. You can also further disambiguate suffixes, for example, if your wide variables are of the form A-one, B-two,.., and you have an unrelated column A-rating, you can ignore the last one by specifying *suffix*= '(?!one|two)'.

Changed in version 0.23.0: When all suffixes are numeric, they are cast to int64/float64.

Returns

DataFrame A DataFrame that contains each stub name as a variable, with new index (*i*, *j*).

Notes

All extra variables are left untouched. This simply uses `pandas.melt` under the hood, but is hard-coded to “do the right thing” in a typical case.

Examples

```
>>> np.random.seed(123)
>>> df = pd.DataFrame({ "A1970" : {0 : "a", 1 : "b", 2 : "c"}, ...
...                               "A1980" : {0 : "d", 1 : "e", 2 : "f"}, ...
...                               "B1970" : {0 : 2.5, 1 : 1.2, 2 : .7}, ...
...                               "B1980" : {0 : 3.2, 1 : 1.3, 2 : .1}, ...
...                               "X"      : dict(zip(range(3), np.random.randn(3))) ...
... })
...
>>> df["id"] = df.index
>>> df
   A1970  A1980  B1970  B1980      X  id
0      a      d    2.5    3.2 -1.085631  0
1      b      e    1.2    1.3  0.997345  1
2      c      f    0.7    0.1  0.282978  2
>>> pd.wide_to_long(df, ["A", "B"], i="id", j="year")
...
          X  A     B
id year
0  1970 -1.085631  a  2.5
1  1970  0.997345  b  1.2
2  1970  0.282978  c  0.7
0  1980 -1.085631  d  3.2
1  1980  0.997345  e  1.3
2  1980  0.282978  f  0.1
```

With multiple id columns

```
>>> df = pd.DataFrame({
...     'famid': [1, 1, 1, 2, 2, 2, 3, 3, 3],
...     'birth': [1, 2, 3, 1, 2, 3, 1, 2, 3],
...     'ht1': [2.8, 2.9, 2.2, 2, 1.8, 1.9, 2.2, 2.3, 2.1],
...     'ht2': [3.4, 3.8, 2.9, 3.2, 2.8, 2.4, 3.3, 3.4, 2.9]
... })
>>> df
   famid  birth  ht1  ht2
0       1      1  2.8  3.4
1       1      2  2.9  3.8
2       1      3  2.2  2.9
3       2      1  2.0  3.2
4       2      2  1.8  2.8
5       2      3  1.9  2.4
6       3      1  2.2  3.3
7       3      2  2.3  3.4
8       3      3  2.1  2.9
>>> l = pd.wide_to_long(df, stubnames='ht', i=['famid', 'birth'], j='age')
>>> l
...
          ht
famid birth age
1       1     1  2.8
```

(continues on next page)

(continued from previous page)

	2	3.4
2	1	2.9
	2	3.8
3	1	2.2
	2	2.9
2	1	2.0
	2	3.2
2	1	1.8
	2	2.8
3	1	1.9
	2	2.4
3	1	2.2
	2	3.3
2	1	2.3
	2	3.4
3	1	2.1
	2	2.9

Going from long back to wide just takes some creative use of *unstack*

```
>>> w = l.unstack()
>>> w.columns = w.columns.map('{0[0]}{0[1]}'.format)
>>> w.reset_index()
   famid  birth  ht1  ht2
0       1      1  2.8  3.4
1       1      2  2.9  3.8
2       1      3  2.2  2.9
3       2      1  2.0  3.2
4       2      2  1.8  2.8
5       2      3  1.9  2.4
6       3      1  2.2  3.3
7       3      2  2.3  3.4
8       3      3  2.1  2.9
```

Less wieldy column names are also handled

```
>>> np.random.seed(0)
>>> df = pd.DataFrame({ 'A(weekly)-2010': np.random.rand(3),
...                      'A(weekly)-2011': np.random.rand(3),
...                      'B(weekly)-2010': np.random.rand(3),
...                      'B(weekly)-2011': np.random.rand(3),
...                      'X' : np.random.randint(3, size=3) })
>>> df['id'] = df.index
>>> df
   A(weekly)-2010  A(weekly)-2011  B(weekly)-2010  B(weekly)-2011  X  id
0      0.548814      0.544883      0.437587      0.383442  0   0
1      0.715189      0.423655      0.891773      0.791725  1   1
2      0.602763      0.645894      0.963663      0.528895  1   2
```

```
>>> pd.wide_to_long(df, ['A(weekly)', 'B(weekly)'],
...                   i='id',
...                   j='year', sep='-')
...
   id year      X  A(weekly)  B(weekly)
0   2010  0    0.548814  0.437587
1   2010  1    0.715189  0.891773
```

(continues on next page)

(continued from previous page)

2	2010	1	0.602763	0.963663
0	2011	0	0.544883	0.383442
1	2011	1	0.423655	0.791725
2	2011	1	0.645894	0.528895

If we have many columns, we could also use a regex to find our stubnames and pass that list on to `wide_to_long`

```
>>> stubnames = sorted(
...     set([match[0] for match in df.columns.str.findall(
...         r'[A-B]\.(.*\)').values if match != []]))
...
>>> list(stubnames)
['A(weekly)', 'B(weekly)']
```

All of the above examples have integers as suffixes. It is possible to have non-integers as suffixes.

```
>>> df = pd.DataFrame({
...     'famid': [1, 1, 1, 2, 2, 2, 3, 3, 3],
...     'birth': [1, 2, 3, 1, 2, 3, 1, 2, 3],
...     'ht_one': [2.8, 2.9, 2.2, 2, 1.8, 1.9, 2.2, 2.3, 2.1],
...     'ht_two': [3.4, 3.8, 2.9, 3.2, 2.8, 2.4, 3.3, 3.4, 2.9]
... })
>>> df
   famid  birth  ht_one  ht_two
0       1      1    2.8    3.4
1       1      2    2.9    3.8
2       1      3    2.2    2.9
3       2      1    2.0    3.2
4       2      2    1.8    2.8
5       2      3    1.9    2.4
6       3      1    2.2    3.3
7       3      2    2.3    3.4
8       3      3    2.1    2.9
```

```
>>> l = pd.wide_to_long(df, stubnames='ht', i=['famid', 'birth'], j='age',
...                         sep='_', suffix='\w+')
>>> l
...
      ht
famid birth age
1      1   one  2.8
        1   two  3.4
        2   one  2.9
        2   two  3.8
        3   one  2.2
        3   two  2.9

(continued from previous page)

3	one	2.1
	two	2.9

4.2.2 Top-level missing data

<code>isna(obj)</code>	Detect missing values for an array-like object.
<code>isnull(obj)</code>	Detect missing values for an array-like object.
<code>notna(obj)</code>	Detect non-missing values for an array-like object.
<code>notnull(obj)</code>	Detect non-missing values for an array-like object.

pandas.isna

`pandas.isna(obj)`

Detect missing values for an array-like object.

This function takes a scalar or array-like object and indicates whether values are missing (NaN in numeric arrays, None or NaT in object arrays, NaT in datetimelike).

Parameters

obj [scalar or array-like] Object to check for null or missing values.

Returns

bool or array-like of bool For scalar input, returns a scalar boolean. For array input, returns an array of boolean indicating whether each corresponding element is missing.

See also:

`notna` Boolean inverse of pandas.isna.

`Series.isna` Detect missing values in a Series.

`DataFrame.isna` Detect missing values in a DataFrame.

`Index.isna` Detect missing values in an Index.

Examples

Scalar arguments (including strings) result in a scalar boolean.

```
>>> pd.isna('dog')
False
```

```
>>> pd.isna(pd.NA)
True
```

```
>>> pd.isna(np.nan)
True
```

ndarrays result in an ndarray of booleans.

```
>>> array = np.array([[1., np.nan, 3], [4., 5., np.nan]])
>>> array
array([[ 1., nan,  3.],
       [ 4.,  5., nan]])
>>> pd.isna(array)
array([[False,  True, False],
       [False, False,  True]])
```

For indexes, an ndarray of booleans is returned.

```
>>> index = pd.DatetimeIndex(["2017-07-05", "2017-07-06", None,
...                             "2017-07-08"])
>>> index
DatetimeIndex(['2017-07-05', '2017-07-06', 'NaT', '2017-07-08'],
               dtype='datetime64[ns]', freq=None)
>>> pd.isna(index)
array([False, False,  True, False])
```

For Series and DataFrame, the same type is returned, containing booleans.

```
>>> df = pd.DataFrame([['ant', 'bee', 'cat'], ['dog', None, 'fly']])
>>> df
   0      1      2
0  ant    bee   cat
1  dog    None   fly
>>> pd.isna(df)
   0      1      2
0  False  False  False
1  False   True  False

>>> pd.isna(df[1])
0    False
1     True
Name: 1, dtype: bool
```

pandas.isnull

`pandas.isnull(obj)`

Detect missing values for an array-like object.

This function takes a scalar or array-like object and indicates whether values are missing (NaN in numeric arrays, None or NaN in object arrays, NaT in datetimelike).

Parameters

`obj` [scalar or array-like] Object to check for null or missing values.

Returns

bool or array-like of bool For scalar input, returns a scalar boolean. For array input, returns an array of boolean indicating whether each corresponding element is missing.

See also:

`notna` Boolean inverse of pandas.isna.

`Series.isna` Detect missing values in a Series.

`DataFrame.isna` Detect missing values in a DataFrame.

`Index.isna` Detect missing values in an Index.

Examples

Scalar arguments (including strings) result in a scalar boolean.

```
>>> pd.isna('dog')
False
```

```
>>> pd.isna(pd.NA)
True
```

```
>>> pd.isna(np.nan)
True
```

ndarrays result in an ndarray of booleans.

```
>>> array = np.array([[1, np.nan, 3], [4, 5, np.nan]])
>>> array
array([[ 1., nan,  3.],
       [ 4.,  5., nan]])
>>> pd.isna(array)
array([[False,  True, False],
       [False, False,  True]])
```

For indexes, an ndarray of booleans is returned.

```
>>> index = pd.DatetimeIndex(["2017-07-05", "2017-07-06", None,
...                             "2017-07-08"])
>>> index
DatetimeIndex(['2017-07-05', '2017-07-06', 'NaT', '2017-07-08'],
               dtype='datetime64[ns]', freq=None)
>>> pd.isna(index)
array([False, False,  True, False])
```

For Series and DataFrame, the same type is returned, containing booleans.

```
>>> df = pd.DataFrame([['ant', 'bee', 'cat'], ['dog', None, 'fly']])
>>> df
   0      1      2
0  ant    bee   cat
1  dog    None   fly
>>> pd.isna(df)
   0      1      2
0  False  False  False
1  False   True  False
```

```
>>> pd.isna(df[1])
0    False
1     True
Name: 1, dtype: bool
```

pandas.notna

`pandas.notna(obj)`

Detect non-missing values for an array-like object.

This function takes a scalar or array-like object and indicates whether values are valid (not missing, which is `NaN` in numeric arrays, `None` or `NaN` in object arrays, `NaT` in datetimelike).

Parameters

obj [array-like or object value] Object to check for *not* null or *non*-missing values.

Returns

bool or array-like of bool For scalar input, returns a scalar boolean. For array input, returns an array of boolean indicating whether each corresponding element is valid.

See also:

[`isna`](#) Boolean inverse of `pandas.notna`.

[`Series.notna`](#) Detect valid values in a Series.

[`DataFrame.notna`](#) Detect valid values in a DataFrame.

[`Index.notna`](#) Detect valid values in an Index.

Examples

Scalar arguments (including strings) result in a scalar boolean.

```
>>> pd.notna('dog')
True
```

```
>>> pd.notna(pd.NA)
False
```

```
>>> pd.notna(np.nan)
False
```

ndarrays result in an ndarray of booleans.

```
>>> array = np.array([[1, np.nan, 3], [4, 5, np.nan]])
>>> array
array([[ 1.,  nan,  3.],
       [ 4.,  5.,  nan]])
>>> pd.notna(array)
array([[ True, False,  True],
       [ True,  True, False]])
```

For indexes, an ndarray of booleans is returned.

```
>>> index = pd.DatetimeIndex(["2017-07-05", "2017-07-06", None,
...                            "2017-07-08"])
>>> index
DatetimeIndex(['2017-07-05', '2017-07-06', 'NaT', '2017-07-08'],
               dtype='datetime64[ns]', freq=None)
>>> pd.notna(index)
array([ True,  True, False,  True])
```

For Series and DataFrame, the same type is returned, containing booleans.

```
>>> df = pd.DataFrame([['ant', 'bee', 'cat'], ['dog', None, 'fly']])
>>> df
   0      1      2
0  ant    bee   cat
1  dog    None  fly
>>> pd.notna(df)
   0      1      2
0  True   True  True
1  True  False  True
```

```
>>> pd.notna(df[1])
0      True
1     False
Name: 1, dtype: bool
```

pandas.notnull

`pandas.notnull(obj)`

Detect non-missing values for an array-like object.

This function takes a scalar or array-like object and indicates whether values are valid (not missing, which is `NaN` in numeric arrays, `None` or `NaN` in object arrays, `NaT` in datetimelike).

Parameters

obj [array-like or object value] Object to check for *not null* or *non-missing* values.

Returns

bool or array-like of bool For scalar input, returns a scalar boolean. For array input, returns an array of boolean indicating whether each corresponding element is valid.

See also:

`isna` Boolean inverse of `pandas.notna`.

`Series.notna` Detect valid values in a Series.

`DataFrame.notna` Detect valid values in a DataFrame.

`Index.notna` Detect valid values in an Index.

Examples

Scalar arguments (including strings) result in a scalar boolean.

```
>>> pd.notna('dog')
True
```

```
>>> pd.notna(pd.NA)
False
```

```
>>> pd.notna(np.nan)
False
```

ndarrays result in an ndarray of booleans.

```
>>> array = np.array([[1, np.nan, 3], [4, 5, np.nan]])
>>> array
array([[ 1., nan,  3.],
       [ 4.,  5., nan]])
>>> pd.notna(array)
array([[ True, False,  True],
       [ True,  True, False]])
```

For indexes, an ndarray of booleans is returned.

```
>>> index = pd.DatetimeIndex(["2017-07-05", "2017-07-06", None,
...                             "2017-07-08"])
>>> index
DatetimeIndex(['2017-07-05', '2017-07-06', 'NaT', '2017-07-08'],
               dtype='datetime64[ns]', freq=None)
>>> pd.notna(index)
array([ True,  True, False,  True])
```

For Series and DataFrame, the same type is returned, containing booleans.

```
>>> df = pd.DataFrame([['ant', 'bee', 'cat'], ['dog', None, 'fly']])
>>> df
   0    1    2
0  ant   bee   cat
1  dog  None   fly
>>> pd.notna(df)
   0    1    2
0  True  True  True
1  True False  True

>>> pd.notna(df[1])
0    True
1   False
Name: 1, dtype: bool
```

4.2.3 Top-level conversions

`to_numeric(arg[, errors, downcast])`

Convert argument to a numeric type.

pandas.to_numeric

`pandas.to_numeric(arg, errors='raise', downcast=None)`

Convert argument to a numeric type.

The default return dtype is `float64` or `int64` depending on the data supplied. Use the `downcast` parameter to obtain other dtypes.

Please note that precision loss may occur if really large numbers are passed in. Due to the internal limitations of `ndarray`, if numbers smaller than `-9223372036854775808` (`np.iinfo(np.int64).min`) or larger than `18446744073709551615` (`np.iinfo(np.uint64).max`) are passed in, it is very likely they will be converted to float so that they can be stored in an `ndarray`. These warnings apply similarly to `Series` since it internally leverages `ndarray`.

Parameters

arg [scalar, list, tuple, 1-d array, or Series]

errors [{‘ignore’, ‘raise’, ‘coerce’}, default ‘raise’]

- If ‘raise’, then invalid parsing will raise an exception.
- If ‘coerce’, then invalid parsing will be set as NaN.
- If ‘ignore’, then invalid parsing will return the input.

downcast [{‘integer’, ‘signed’, ‘unsigned’, ‘float’}, default None] If not None, and if the data has been successfully cast to a numerical dtype (or if the data was numeric to begin with), downcast that resulting data to the smallest numerical dtype possible according to the following rules:

- ‘integer’ or ‘signed’: smallest signed int dtype (min.: np.int8)
- ‘unsigned’: smallest unsigned int dtype (min.: np.uint8)
- ‘float’: smallest float dtype (min.: np.float32)

As this behaviour is separate from the core conversion to numeric values, any errors raised during the downcasting will be surfaced regardless of the value of the ‘errors’ input.

In addition, downcasting will only occur if the size of the resulting data’s dtype is strictly larger than the dtype it is to be cast to, so if none of the dtypes checked satisfy that specification, no downcasting will be performed on the data.

Returns

ret [numeric if parsing succeeded.] Return type depends on input. Series if Series, otherwise ndarray.

See also:

[`DataFrame.astype`](#) Cast argument to a specified dtype.

[`to_datetime`](#) Convert argument to datetime.

[`to_timedelta`](#) Convert argument to timedelta.

[`numpy.ndarray.astype`](#) Cast a numpy array to a specified type.

[`convert_dtypes`](#) Convert dtypes.

Examples

Take separate series and convert to numeric, coercing when told to

```
>>> s = pd.Series(['1.0', '2', '-3'])
>>> pd.to_numeric(s)
0    1.0
1    2.0
2   -3.0
dtype: float64
>>> pd.to_numeric(s, downcast='float')
0    1.0
1    2.0
2   -3.0
dtype: float32
>>> pd.to_numeric(s, downcast='signed')
0    1
```

(continues on next page)

(continued from previous page)

```

1    2
2   -3
dtype: int8
>>> s = pd.Series(['apple', '1.0', '2', '-3'])
>>> pd.to_numeric(s, errors='ignore')
0    apple
1      1.0
2      2
3     -3
dtype: object
>>> pd.to_numeric(s, errors='coerce')
0      NaN
1      1.0
2      2.0
3     -3.0
dtype: float64

```

4.2.4 Top-level dealing with datetimelike

<code>to_datetime(arg[, errors, dayfirst, ...])</code>	Convert argument to datetime.
<code>to_timedelta(arg[, unit, errors])</code>	Convert argument to timedelta.
<code>date_range([start, end, periods, freq, tz, ...])</code>	Return a fixed frequency DatetimeIndex.
<code>bdate_range([start, end, periods, freq, tz, ...])</code>	Return a fixed frequency DatetimeIndex, with business day as the default frequency.
<code>period_range([start, end, periods, freq, name])</code>	Return a fixed frequency PeriodIndex.
<code>timedelta_range([start, end, periods, freq, ...])</code>	Return a fixed frequency TimedeltaIndex, with day as the default frequency.
<code>infer_freq(index, warn)</code>	Infer the most likely frequency given the input index.

pandas.to_datetime

`pandas.to_datetime(arg, errors='raise', dayfirst=False, yearfirst=False, utc=None, format=None, exact=True, unit=None, infer_datetime_format=False, origin='unix', cache=True)`
Convert argument to datetime.

Parameters

arg [int, float, str, datetime, list, tuple, 1-d array, Series DataFrame/dict-like] The object to convert to a datetime.

errors [{‘ignore’, ‘raise’, ‘coerce’}, default ‘raise’]

- If ‘raise’, then invalid parsing will raise an exception.
- If ‘coerce’, then invalid parsing will be set as NaT.
- If ‘ignore’, then invalid parsing will return the input.

dayfirst [bool, default False] Specify a date parse order if *arg* is str or its list-likes. If True, parses dates with the day first, eg 10/11/12 is parsed as 2012-11-10. Warning: dayfirst=True is not strict, but will prefer to parse with day first (this is a known bug, based on dateutil behavior).

yearfirst [bool, default False] Specify a date parse order if *arg* is str or its list-likes.

- If True parses dates with the year first, eg 10/11/12 is parsed as 2010-11-12.
- If both dayfirst and yearfirst are True, yearfirst is preceded (same as dateutil).

Warning: yearfirst=True is not strict, but will prefer to parse with year first (this is a known bug, based on dateutil behavior).

utc [bool, default None] Return UTC DatetimeIndex if True (converting any tz-aware datetime.datetime objects as well).

format [str, default None] The strftime to parse time, eg "%d/%m/%Y", note that "%f" will parse all the way up to nanoseconds. See strftime documentation for more information on choices: <https://docs.python.org/3/library/datetime.html#strftime-and-strptime-behavior>.

exact [bool, True by default] Behaves as: - If True, require an exact format match. - If False, allow the format to match anywhere in the target string.

unit [str, default 'ns'] The unit of the arg (D,s,ms,us,ns) denote the unit, which is an integer or float number. This will be based off the origin. Example, with unit='ms' and origin='unix' (the default), this would calculate the number of milliseconds to the unix epoch start.

infer_datetime_format [bool, default False] If True and no *format* is given, attempt to infer the format of the datetime strings, and if it can be inferred, switch to a faster method of parsing them. In some cases this can increase the parsing speed by ~5-10x.

origin [scalar, default 'unix'] Define the reference date. The numeric values would be parsed as number of units (defined by *unit*) since this reference date.

- If 'unix' (or POSIX) time; origin is set to 1970-01-01.
- If 'julian', unit must be 'D', and origin is set to beginning of Julian Calendar. Julian day number 0 is assigned to the day starting at noon on January 1, 4713 BC.
- If Timestamp convertible, origin is set to Timestamp identified by origin.

cache [bool, default True] If True, use a cache of unique, converted dates to apply the datetime conversion. May produce significant speed-up when parsing duplicate date strings, especially ones with timezone offsets. The cache is only used when there are at least 50 values. The presence of out-of-bounds values will render the cache unusable and may slow down parsing.

New in version 0.23.0.

Changed in version 0.25.0: - changed default value from False to True.

Returns

datetime If parsing succeeded. Return type depends on input:

- list-like: DatetimeIndex
- Series: Series of datetime64 dtype
- scalar: Timestamp

In case when it is not possible to return designated types (e.g. when any element of input is before Timestamp.min or after Timestamp.max) return will have datetime.datetime type (or corresponding array/Series).

See also:

`DataFrame.astype` Cast argument to a specified dtype.

`to_timedelta` Convert argument to timedelta.

convert_dtypes Convert dtypes.

Examples

Assembling a datetime from multiple columns of a DataFrame. The keys can be common abbreviations like ['year', 'month', 'day', 'minute', 'second', 'ms', 'us', 'ns']) or plurals of the same

```
>>> df = pd.DataFrame({'year': [2015, 2016],
...                      'month': [2, 3],
...                      'day': [4, 5]})
>>> pd.to_datetime(df)
0    2015-02-04
1    2016-03-05
dtype: datetime64[ns]
```

If a date does not meet the timestamp limitations, passing errors='ignore' will return the original input instead of raising any exception.

Passing errors='coerce' will force an out-of-bounds date to NaT, in addition to forcing non-dates (or non-parseable dates) to NaT.

```
>>> pd.to_datetime('13000101', format='%Y%m%d', errors='ignore')
datetime.datetime(1300, 1, 1, 0, 0)
>>> pd.to_datetime('13000101', format='%Y%m%d', errors='coerce')
NaT
```

Passing infer_datetime_format=True can often-times speedup a parsing if its not an ISO8601 format exactly, but in a regular format.

```
>>> s = pd.Series(['3/11/2000', '3/12/2000', '3/13/2000'] * 1000)
>>> s.head()
0    3/11/2000
1    3/12/2000
2    3/13/2000
3    3/11/2000
4    3/12/2000
dtype: object
```

```
>>> %timeit pd.to_datetime(s, infer_datetime_format=True)
100 loops, best of 3: 10.4 ms per loop
```

```
>>> %timeit pd.to_datetime(s, infer_datetime_format=False)
1 loop, best of 3: 471 ms per loop
```

Using a unix epoch time

```
>>> pd.to_datetime(1490195805, unit='s')
Timestamp('2017-03-22 15:16:45')
>>> pd.to_datetime(1490195805433502912, unit='ns')
Timestamp('2017-03-22 15:16:45.433502912')
```

Warning: For float arg, precision rounding might happen. To prevent unexpected behavior use a fixed-width exact type.

Using a non-unix epoch origin

```
>>> pd.to_datetime([1, 2, 3], unit='D',
...                  origin=pd.Timestamp('1960-01-01'))
DatetimeIndex(['1960-01-02', '1960-01-03', '1960-01-04'], dtype='datetime64[ns]', freq=None)
```

pandas.to_timedelta

`pandas.to_timedelta(arg, unit='ns', errors='raise')`

Convert argument to timedelta.

Timedeltas are absolute differences in times, expressed in difference units (e.g. days, hours, minutes, seconds). This method converts an argument from a recognized timedelta format / value into a Timedelta type.

Parameters

`arg` [str, timedelta, list-like or Series] The data to be converted to timedelta.

`unit` [str, default ‘ns’] Denotes the unit of the arg. Possible values: (‘Y’, ‘M’, ‘W’, ‘D’, ‘days’, ‘day’, ‘hours’, ‘hour’, ‘hr’, ‘h’, ‘m’, ‘minute’, ‘min’, ‘minutes’, ‘T’, ‘S’, ‘seconds’, ‘sec’, ‘second’, ‘ms’, ‘milliseconds’, ‘millisecond’, ‘milli’, ‘millis’, ‘L’, ‘us’, ‘microseconds’, ‘microsecond’, ‘micro’, ‘micros’, ‘U’, ‘ns’, ‘nanoseconds’, ‘nano’, ‘nanos’, ‘nanosecond’, ‘N’).

`errors` [{‘ignore’, ‘raise’, ‘coerce’}, default ‘raise’]

- If ‘raise’, then invalid parsing will raise an exception.
- If ‘coerce’, then invalid parsing will be set as NaT.
- If ‘ignore’, then invalid parsing will return the input.

Returns

`timedelta64 or numpy.array of timedelta64` Output type returned if parsing succeeded.

See also:

`DataFrame.astype` Cast argument to a specified dtype.

`to_datetime` Convert argument to datetime.

`convert_dtypes` Convert dtypes.

Examples

Parsing a single string to a Timedelta:

```
>>> pd.to_timedelta('1 days 06:05:01.00003')
Timedelta('1 days 06:05:01.000030')
>>> pd.to_timedelta('15.5us')
Timedelta('0 days 00:00:00.000015')
```

Parsing a list or array of strings:

```
>>> pd.to_timedelta(['1 days 06:05:01.00003', '15.5us', 'nan'])
TimedeltaIndex(['1 days 06:05:01.000030', '0 days 00:00:00.000015', NaT],
               dtype='timedelta64[ns]', freq=None)
```

Converting numbers by specifying the `unit` keyword argument:

```
>>> pd.to_timedelta(np.arange(5), unit='s')
TimedeltaIndex(['00:00:00', '00:00:01', '00:00:02',
                 '00:00:03', '00:00:04'],
                dtype='timedelta64[ns]', freq=None)
>>> pd.to_timedelta(np.arange(5), unit='d')
TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'],
                dtype='timedelta64[ns]', freq=None)
```

pandas.date_range

`pandas.date_range(start=None, end=None, periods=None, freq=None, tz=None, normalize=False, name=None, closed=None, **kwargs) → pandas.core.indexes.dates.DatetimeIndex`
Return a fixed frequency DatetimeIndex.

Parameters

start [str or datetime-like, optional] Left bound for generating dates.
end [str or datetime-like, optional] Right bound for generating dates.
periods [int, optional] Number of periods to generate.
freq [str or DateOffset, default ‘D’] Frequency strings can have multiples, e.g. ‘5H’. See [here](#) for a list of frequency aliases.
tz [str or tzinfo, optional] Time zone name for returning localized DatetimeIndex, for example ‘Asia/Hong_Kong’. By default, the resulting DatetimeIndex is timezone-naive.
normalize [bool, default False] Normalize start/end dates to midnight before generating date range.
name [str, default None] Name of the resulting DatetimeIndex.
closed [{None, ‘left’, ‘right’}, optional] Make the interval closed with respect to the given frequency to the ‘left’, ‘right’, or both sides (None, the default).
****kwargs** For compatibility. Has no effect on the result.

Returns

rng [DatetimeIndex]

See also:

DatetimeIndex An immutable container for datetimes.

timedelta_range Return a fixed frequency TimedeltaIndex.

period_range Return a fixed frequency PeriodIndex.

interval_range Return a fixed frequency IntervalIndex.

Notes

Of the four parameters `start`, `end`, `periods`, and `freq`, exactly three must be specified. If `freq` is omitted, the resulting `DatetimeIndex` will have `periods` linearly spaced elements between `start` and `end` (closed on both sides).

To learn more about the frequency strings, please see [this link](#).

Examples

Specifying the values

The next four examples generate the same `DatetimeIndex`, but vary the combination of `start`, `end` and `periods`.

Specify `start` and `end`, with the default daily frequency.

```
>>> pd.date_range(start='1/1/2018', end='1/08/2018')
DatetimeIndex(['2018-01-01', '2018-01-02', '2018-01-03', '2018-01-04',
               '2018-01-05', '2018-01-06', '2018-01-07', '2018-01-08'],
              dtype='datetime64[ns]', freq='D')
```

Specify `start` and `periods`, the number of periods (days).

```
>>> pd.date_range(start='1/1/2018', periods=8)
DatetimeIndex(['2018-01-01', '2018-01-02', '2018-01-03', '2018-01-04',
               '2018-01-05', '2018-01-06', '2018-01-07', '2018-01-08'],
              dtype='datetime64[ns]', freq='D')
```

Specify `end` and `periods`, the number of periods (days).

```
>>> pd.date_range(end='1/1/2018', periods=8)
DatetimeIndex(['2017-12-25', '2017-12-26', '2017-12-27', '2017-12-28',
               '2017-12-29', '2017-12-30', '2017-12-31', '2018-01-01'],
              dtype='datetime64[ns]', freq='D')
```

Specify `start`, `end`, and `periods`; the frequency is generated automatically (linearly spaced).

```
>>> pd.date_range(start='2018-04-24', end='2018-04-27', periods=3)
DatetimeIndex(['2018-04-24 00:00:00', '2018-04-25 12:00:00',
               '2018-04-27 00:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Other Parameters

Changed the `freq` (frequency) to '`M`' (month end frequency).

```
>>> pd.date_range(start='1/1/2018', periods=5, freq='M')
DatetimeIndex(['2018-01-31', '2018-02-28', '2018-03-31', '2018-04-30',
               '2018-05-31'],
              dtype='datetime64[ns]', freq='M')
```

Multiples are allowed

```
>>> pd.date_range(start='1/1/2018', periods=5, freq='3M')
DatetimeIndex(['2018-01-31', '2018-04-30', '2018-07-31', '2018-10-31',
               '2019-01-31'],
              dtype='datetime64[ns]', freq='3M')
```

freq can also be specified as an Offset object.

```
>>> pd.date_range(start='1/1/2018', periods=5, freq=pd.offsets.MonthEnd(3))
DatetimeIndex(['2018-01-31', '2018-04-30', '2018-07-31', '2018-10-31',
               '2019-01-31'],
              dtype='datetime64[ns]', freq='3M')
```

Specify *tz* to set the timezone.

```
>>> pd.date_range(start='1/1/2018', periods=5, tz='Asia/Tokyo')
DatetimeIndex(['2018-01-01 00:00:00+09:00', '2018-01-02 00:00:00+09:00',
               '2018-01-03 00:00:00+09:00', '2018-01-04 00:00:00+09:00',
               '2018-01-05 00:00:00+09:00'],
              dtype='datetime64[ns, Asia/Tokyo]', freq='D')
```

closed controls whether to include *start* and *end* that are on the boundary. The default includes boundary points on either end.

```
>>> pd.date_range(start='2017-01-01', end='2017-01-04', closed=None)
DatetimeIndex(['2017-01-01', '2017-01-02', '2017-01-03', '2017-01-04'],
              dtype='datetime64[ns]', freq='D')
```

Use *closed='left'* to exclude *end* if it falls on the boundary.

```
>>> pd.date_range(start='2017-01-01', end='2017-01-04', closed='left')
DatetimeIndex(['2017-01-01', '2017-01-02', '2017-01-03'],
              dtype='datetime64[ns]', freq='D')
```

Use *closed='right'* to exclude *start* if it falls on the boundary.

```
>>> pd.date_range(start='2017-01-01', end='2017-01-04', closed='right')
DatetimeIndex(['2017-01-02', '2017-01-03', '2017-01-04'],
              dtype='datetime64[ns]', freq='D')
```

pandas.bdate_range

```
pandas.bdate_range(start=None, end=None, periods=None, freq='B', tz=None, normalize=True,
                    name=None, weekmask=None, holidays=None, closed=None, **kwargs) → pandas.core.indexes.datetimes.DatetimeIndex
```

Return a fixed frequency DatetimeIndex, with business day as the default frequency.

Parameters

- start** [str or datetime-like, default None] Left bound for generating dates.
- end** [str or datetime-like, default None] Right bound for generating dates.
- periods** [int, default None] Number of periods to generate.
- freq** [str or DateOffset, default ‘B’ (business daily)] Frequency strings can have multiples, e.g. ‘5H’.
- tz** [str or None] Time zone name for returning localized DatetimeIndex, for example Asia/Beijing.
- normalize** [bool, default False] Normalize start/end dates to midnight before generating date range.
- name** [str, default None] Name of the resulting DatetimeIndex.

weekmask [str or None, default None] Weekmask of valid business days, passed to `numpy.busdaycalendar`, only used when custom frequency strings are passed. The default value None is equivalent to ‘Mon Tue Wed Thu Fri’.

New in version 0.21.0.

holidays [list-like or None, default None] Dates to exclude from the set of valid business days, passed to `numpy.busdaycalendar`, only used when custom frequency strings are passed.

New in version 0.21.0.

closed [str, default None] Make the interval closed with respect to the given frequency to the ‘left’, ‘right’, or both sides (None).

****kwargs** For compatibility. Has no effect on the result.

Returns

`DatetimeIndex`

Notes

Of the four parameters: `start`, `end`, `periods`, and `freq`, exactly three must be specified. Specifying `freq` is a requirement for `bdate_range`. Use `date_range` if specifying `freq` is not desired.

To learn more about the frequency strings, please see [this link](#).

Examples

Note how the two weekend days are skipped in the result.

```
>>> pd.bdate_range(start='1/1/2018', end='1/08/2018')
DatetimeIndex(['2018-01-01', '2018-01-02', '2018-01-03', '2018-01-04',
               '2018-01-05', '2018-01-08'],
              dtype='datetime64[ns]', freq='B')
```

pandas.period_range

`pandas.period_range(start=None, end=None, periods=None, freq=None, name=None)` → `pandas.core.indexes.period.PeriodIndex`

Return a fixed frequency PeriodIndex.

The day (calendar) is the default frequency.

Parameters

start [str or period-like, default None] Left bound for generating periods.

end [str or period-like, default None] Right bound for generating periods.

periods [int, default None] Number of periods to generate.

freq [str or DateOffset, optional] Frequency alias. By default the freq is taken from `start` or `end` if those are Period objects. Otherwise, the default is "D" for daily frequency.

name [str, default None] Name of the resulting PeriodIndex.

Returns

`PeriodIndex`

Notes

Of the three parameters: `start`, `end`, and `periods`, exactly two must be specified.

To learn more about the frequency strings, please see [this link](#).

Examples

```
>>> pd.period_range(start='2017-01-01', end='2018-01-01', freq='M')
PeriodIndex(['2017-01', '2017-02', '2017-03', '2017-04', '2017-05',
             '2017-06', '2017-06', '2017-07', '2017-08', '2017-09',
             '2017-10', '2017-11', '2017-12', '2018-01'],
            dtype='period[M]', freq='M')
```

If `start` or `end` are `Period` objects, they will be used as anchor endpoints for a `PeriodIndex` with frequency matching that of the `period_range` constructor.

```
>>> pd.period_range(start=pd.Period('2017Q1', freq='Q'),
...                   end=pd.Period('2017Q2', freq='Q'), freq='M')
PeriodIndex(['2017-03', '2017-04', '2017-05', '2017-06'],
            dtype='period[M]', freq='M')
```

pandas.timedelta_range

`pandas.timedelta_range`(`start=None`, `end=None`, `periods=None`, `freq=None`, `name=None`, `closed=None`) → `pandas.core.indexes.timedeltas.TimedeltaIndex`

Return a fixed frequency `TimedeltaIndex`, with day as the default frequency.

Parameters

start [str or `timedelta`-like, default `None`] Left bound for generating `timedeltas`.

end [str or `timedelta`-like, default `None`] Right bound for generating `timedeltas`.

periods [int, default `None`] Number of periods to generate.

freq [str or `DateOffset`, default ‘D’] Frequency strings can have multiples, e.g. ‘5H’.

name [str, default `None`] Name of the resulting `TimedeltaIndex`.

closed [str, default `None`] Make the interval closed with respect to the given frequency to the ‘left’, ‘right’, or both sides (`None`).

Returns

rng [`TimedeltaIndex`]

Notes

Of the four parameters `start`, `end`, `periods`, and `freq`, exactly three must be specified. If `freq` is omitted, the resulting `TimedeltaIndex` will have periods linearly spaced elements between `start` and `end` (closed on both sides).

To learn more about the frequency strings, please see [this link](#).

Examples

```
>>> pd.timedelta_range(start='1 day', periods=4)
TimedeltaIndex(['1 days', '2 days', '3 days', '4 days'],
               dtype='timedelta64[ns]', freq='D')
```

The `closed` parameter specifies which endpoint is included. The default behavior is to include both endpoints.

```
>>> pd.timedelta_range(start='1 day', periods=4, closed='right')
TimedeltaIndex(['2 days', '3 days', '4 days'],
               dtype='timedelta64[ns]', freq='D')
```

The `freq` parameter specifies the frequency of the TimedeltaIndex. Only fixed frequencies can be passed, non-fixed frequencies such as 'M' (month end) will raise.

```
>>> pd.timedelta_range(start='1 day', end='2 days', freq='6H')
TimedeltaIndex(['1 days 00:00:00', '1 days 06:00:00', '1 days 12:00:00',
                '1 days 18:00:00', '2 days 00:00:00'],
               dtype='timedelta64[ns]', freq='6H')
```

Specify `start`, `end`, and `periods`; the frequency is generated automatically (linearly spaced).

```
>>> pd.timedelta_range(start='1 day', end='5 days', periods=4)
TimedeltaIndex(['1 days 00:00:00', '2 days 08:00:00', '3 days 16:00:00',
                '5 days 00:00:00'],
               dtype='timedelta64[ns]', freq=None)
```

pandas.infer_freq

`pandas.infer_freq(index, warn = True) → Union[str, NoneType]`

Infer the most likely frequency given the input index. If the frequency is uncertain, a warning will be printed.

Parameters

`index` [DatetimeIndex or TimedeltaIndex] If passed a Series will use the values of the series (NOT THE INDEX).

`warn` [bool, default True]

Returns

`str or None` None if no discernible frequency TypeError if the index is not datetime-like ValueError if there are less than three values.

4.2.5 Top-level dealing with intervals

<code>interval_range([start, end, periods, freq, ...])</code>	Return a fixed frequency IntervalIndex.
---	---

pandas.interval_range

```
pandas.interval_range(start=None, end=None, periods=None, freq=None, name=None, closed='right')
```

Return a fixed frequency IntervalIndex.

Parameters

start [numeric or datetime-like, default None] Left bound for generating intervals.

end [numeric or datetime-like, default None] Right bound for generating intervals.

periods [int, default None] Number of periods to generate.

freq [numeric, str, or DateOffset, default None] The length of each interval. Must be consistent with the type of start and end, e.g. 2 for numeric, or '5H' for datetime-like. Default is 1 for numeric and 'D' for datetime-like.

name [str, default None] Name of the resulting IntervalIndex.

closed [{‘left’, ‘right’, ‘both’, ‘neither’}, default ‘right’] Whether the intervals are closed on the left-side, right-side, both or neither.

Returns

IntervalIndex

See also:

IntervalIndex An Index of intervals that are all closed on the same side.

Notes

Of the four parameters `start`, `end`, `periods`, and `freq`, exactly three must be specified. If `freq` is omitted, the resulting `IntervalIndex` will have `periods` linearly spaced elements between `start` and `end`, inclusively.

To learn more about datetime-like frequency strings, please see [this link](#).

Examples

Numeric `start` and `end` is supported.

```
>>> pd.interval_range(start=0, end=5)
IntervalIndex([(0, 1], (1, 2], (2, 3], (3, 4], (4, 5]),
              closed='right', dtype='interval[int64]')
```

Additionally, datetime-like input is also supported.

```
>>> pd.interval_range(start=pd.Timestamp('2017-01-01'),
...                     end=pd.Timestamp('2017-01-04'))
IntervalIndex([(2017-01-01, 2017-01-02], (2017-01-02, 2017-01-03],
               (2017-01-03, 2017-01-04]],
              closed='right', dtype='interval[datetime64[ns]]')
```

The `freq` parameter specifies the frequency between the left and right endpoints of the individual intervals within the `IntervalIndex`. For numeric `start` and `end`, the frequency must also be numeric.

```
>>> pd.interval_range(start=0, periods=4, freq=1.5)
IntervalIndex([(0.0, 1.5], (1.5, 3.0], (3.0, 4.5], (4.5, 6.0]),
              closed='right', dtype='interval[float64]')
```

Similarly, for datetime-like start and end, the frequency must be convertible to a DateOffset.

```
>>> pd.interval_range(start=pd.Timestamp('2017-01-01'),
...                     periods=3, freq='MS')
IntervalIndex([(2017-01-01, 2017-02-01], (2017-02-01, 2017-03-01],
               (2017-03-01, 2017-04-01]],
              closed='right', dtype='interval[datetime64[ns]]')
```

Specify start, end, and periods; the frequency is generated automatically (linearly spaced).

```
>>> pd.interval_range(start=0, end=6, periods=4)
IntervalIndex([(0.0, 1.5], (1.5, 3.0], (3.0, 4.5], (4.5, 6.0]),
              closed='right',
              dtype='interval[float64]')
```

The closed parameter specifies which endpoints of the individual intervals within the IntervalIndex are closed.

```
>>> pd.interval_range(end=5, periods=4, closed='both')
IntervalIndex([[1, 2], [2, 3], [3, 4], [4, 5]],
              closed='both', dtype='interval[int64]')
```

4.2.6 Top-level evaluation

`eval(expr[, parser, truediv, local_dict, ...])`

Evaluate a Python expression as a string using various backends.

pandas.eval

`pandas.eval(expr, parser='pandas', engine: Union[str, NoneType] = None, truediv=<object object at 0x7f6dabd2f350>, local_dict=None, global_dict=None, resolvers=(), level=0, target=None, inplace=False)`

Evaluate a Python expression as a string using various backends.

The following arithmetic operations are supported: +, -, *, /, **, %, // (python engine only) along with the following boolean operations: | (or), & (and), and ~ (not). Additionally, the 'pandas' parser allows the use of and, or, and not with the same semantics as the corresponding bitwise operators. `Series` and `DataFrame` objects are supported and behave as they would with plain ol' Python evaluation.

Parameters

expr [str] The expression to evaluate. This string cannot contain any Python statements, only Python expressions.

parser [{‘pandas’, ‘python’}, default ‘pandas’] The parser to use to construct the syntax tree from the expression. The default of ‘pandas’ parses code slightly different than standard Python. Alternatively, you can parse an expression using the ‘python’ parser to retain strict Python semantics. See the [enhancing performance](#) documentation for more details.

engine [{‘python’, ‘numexpr’}, default ‘numexpr’] The engine used to evaluate the expression. Supported engines are

- `None` : tries to use `numexpr`, falls back to `python`
- '`numexpr`' : This default engine evaluates pandas objects using `numexpr` for large speed ups in complex expressions with large frames.
- '`python`' : Performs operations as if you had `eval'd` in top level python. This engine is generally not that useful.

More backends may be available in the future.

truediv [bool, optional] Whether to use true division, like in Python >= 3. deprecated:: 1.0.0

local_dict [dict or None, optional] A dictionary of local variables, taken from `locals()` by default.

global_dict [dict or None, optional] A dictionary of global variables, taken from `globals()` by default.

resolvers [list of dict-like or None, optional] A list of objects implementing the `__getitem__` special method that you can use to inject an additional collection of namespaces to use for variable lookup. For example, this is used in the `query()` method to inject the `DataFrame.index` and `DataFrame.columns` variables that refer to their respective `DataFrame` instance attributes.

level [int, optional] The number of prior stack frames to traverse and add to the current scope. Most users will **not** need to change this parameter.

target [object, optional, default `None`] This is the target object for assignment. It is used when there is variable assignment in the expression. If so, then `target` must support item assignment with string keys, and if a copy is being returned, it must also support `.copy()`.

inplace [bool, default `False`] If `target` is provided, and the expression mutates `target`, whether to modify `target` inplace. Otherwise, return a copy of `target` with the mutation.

Returns

`ndarray, numeric scalar, DataFrame, Series`

Raises

ValueError There are many instances where such an error can be raised:

- `target=None`, but the expression is multiline.
- The expression is multiline, but not all them have item assignment. An example of such an arrangement is this:

`a = b + 1 a + 2`

Here, there are expressions on different lines, making it multiline, but the last line has no variable assigned to the output of `a + 2`.

- `inplace=True`, but the expression is missing item assignment.
- Item assignment is provided, but the `target` does not support string item assignment.
- Item assignment is provided and `inplace=False`, but the `target` does not support the `.copy()` method

See also:

`DataFrame.query`

`DataFrame.eval`

Notes

The `dtype` of any objects involved in an arithmetic % operation are recursively cast to `float 64`.

See the [enhancing performance](#) documentation for more details.

4.2.7 Hashing

<code>util.hash_array(vals, encoding, hash_key, ...)</code>	Given a 1d array, return an array of deterministic integers.
<code>util.hash_pandas_object(obj, index, ...)</code>	Return a data hash of the Index/Series/DataFrame.

pandas.util.hash_array

`pandas.util.hash_array(vals, encoding: str = 'utf8', hash_key: str = '0123456789123456', categorize: bool = True)`

Given a 1d array, return an array of deterministic integers.

Parameters

`vals` [ndarray, Categorical]

`encoding` [str, default ‘utf8’] Encoding for data & key when strings.

`hash_key` [str, default `_default_hash_key`] Hash_key for string key to encode.

`categorize` [bool, default True] Whether to first categorize object arrays before hashing. This is more efficient when the array contains duplicate values.

Returns

1d uint64 numpy array of hash values, same length as the vals

pandas.util.hash_pandas_object

`pandas.util.hash_pandas_object(obj, index: bool = True, encoding: str = 'utf8', hash_key: Union[str, NoneType] = '0123456789123456', categorize: bool = True)`

Return a data hash of the Index/Series/DataFrame.

Parameters

`index` [bool, default True] Include the index in the hash (if Series/DataFrame).

`encoding` [str, default ‘utf8’] Encoding for data & key when strings.

`hash_key` [str, default `_default_hash_key`] Hash_key for string key to encode.

`categorize` [bool, default True] Whether to first categorize object arrays before hashing. This is more efficient when the array contains duplicate values.

Returns

Series of uint64, same length as the object

4.2.8 Testing

```
test([extra_args])
```

pandas.test

```
pandas.test(extra_args=None)  
{ { header } }
```

4.3 Series

4.3.1 Constructor

<code>Series([data, index, dtype, name, copy, ...])</code>	One-dimensional ndarray with axis labels (including time series).
--	---

pandas.Series

```
class pandas.Series(data=None, index=None, dtype=None, name=None, copy=False, fastpath=False)
```

One-dimensional ndarray with axis labels (including time series).

Labels need not be unique but must be a hashable type. The object supports both integer- and label-based indexing and provides a host of methods for performing operations involving the index. Statistical methods from ndarray have been overridden to automatically exclude missing data (currently represented as NaN).

Operations between Series (+, -, /, *, *) align values based on their associated index values— they need not be the same length. The result index will be the sorted union of the two indexes.

Parameters

data [array-like, Iterable, dict, or scalar value] Contains data stored in Series.

Changed in version 0.23.0: If data is a dict, argument order is maintained for Python 3.6 and later.

index [array-like or Index (1d)] Values must be hashable and have the same length as *data*. Non-unique index values are allowed. Will default to RangeIndex (0, 1, 2, ..., n) if not provided. If both a dict and index sequence are used, the index will override the keys found in the dict.

dtype [str, numpy.dtype, or ExtensionDtype, optional] Data type for the output Series. If not specified, this will be inferred from *data*. See the [user guide](#) for more usages.

name [str, optional] The name to give to the Series.

copy [bool, default False] Copy input data.

Attributes

<code>T</code>	Return the transpose, which is by definition self.
<code>array</code>	The ExtensionArray of the data backing this Series or Index.
<code>at</code>	Access a single value for a row/column label pair.
<code>attrs</code>	Dictionary of global attributes on this object.
<code>axes</code>	Return a list of the row axis labels.
<code>dtype</code>	Return the dtype object of the underlying data.
<code>dtypes</code>	Return the dtype object of the underlying data.
<code>hasnans</code>	Return if I have any nans; enables various perf speedups.
<code>iat</code>	Access a single value for a row/column pair by integer position.
<code>iloc</code>	Purely integer-location based indexing for selection by position.
<code>index</code>	The index (axis labels) of the Series.
<code>is_monotonic</code>	Return boolean if values in the object are monotonic_increasing.
<code>is_monotonic_decreasing</code>	Return boolean if values in the object are monotonic_decreasing.
<code>is_monotonic_increasing</code>	Return boolean if values in the object are monotonic_increasing.
<code>is_unique</code>	Return boolean if values in the object are unique.
<code>loc</code>	Access a group of rows and columns by label(s) or a boolean array.
<code>nbytes</code>	Return the number of bytes in the underlying data.
<code>ndim</code>	Number of dimensions of the underlying data, by definition 1.
<code>shape</code>	Return a tuple of the shape of the underlying data.
<code>size</code>	Return the number of elements in the underlying data.
<code>values</code>	Return Series as ndarray or ndarray-like depending on the dtype.

pandas.Series.T

property Series.T

Return the transpose, which is by definition self.

pandas.Series.array

property Series.array

The ExtensionArray of the data backing this Series or Index.

New in version 0.24.0.

Returns

ExtensionArray An ExtensionArray of the values stored within. For extension types, this is the actual array. For NumPy native types, this is a thin (no copy) wrapper around `numpy.ndarray`.

.array differs .values which may require converting the data to a different form.

See also:

[Index.to_numpy](#) Similar method that always returns a NumPy array.

[Series.to_numpy](#) Similar method that always returns a NumPy array.

Notes

This table lays out the different array types for each extension dtype within pandas.

dtype	array type
category	Categorical
period	PeriodArray
interval	IntervalArray
IntegerNA	IntegerArray
string	StringArray
boolean	BooleanArray
datetime64[ns, tz]	DatetimeArray

For any 3rd-party extension types, the array type will be an ExtensionArray.

For all remaining dtypes .array will be a arrays.NumpyExtensionArray wrapping the actual ndarray stored within. If you absolutely need a NumPy array (possibly with copying / coercing data), then use [Series.to_numpy\(\)](#) instead.

Examples

For regular NumPy types like int, and float, a PandasArray is returned.

```
>>> pd.Series([1, 2, 3]).array
<PandasArray>
[1, 2, 3]
Length: 3, dtype: int64
```

For extension types, like Categorical, the actual ExtensionArray is returned

```
>>> ser = pd.Series(pd.Categorical(['a', 'b', 'a']))
>>> ser.array
[a, b, a]
Categories (2, object): [a, b]
```

pandas.Series.at

property Series.at

Access a single value for a row/column label pair.

Similar to `loc`, in that both provide label-based lookups. Use `at` if you only need to get or set a single value in a DataFrame or Series.

Raises

KeyError If ‘label’ does not exist in DataFrame.

See also:

`DataFrame.iat` Access a single value for a row/column pair by integer position.

`DataFrame.loc` Access a group of rows and columns by label(s).

`Series.at` Access a single value using a label.

Examples

```
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
...                      index=[4, 5, 6], columns=['A', 'B', 'C'])
>>> df
   A    B    C
4  0    2    3
5  0    4    1
6  10   20   30
```

Get value at specified row/column pair

```
>>> df.at[4, 'B']
2
```

Set value at specified row/column pair

```
>>> df.at[4, 'B'] = 10
>>> df.at[4, 'B']
10
```

Get value within a Series

```
>>> df.loc[5].at['B']
4
```

pandas.Series.attrs**property Series.attrs**

Dictionary of global attributes on this object.

Warning: attrs is experimental and may change without warning.

pandas.Series.axes**property Series.axes**

Return a list of the row axis labels.

pandas.Series.dtype

property Series.dtype

Return the dtype object of the underlying data.

pandas.Series.dtypes

property Series.dtypes

Return the dtype object of the underlying data.

pandas.Series.hasnans

property Series.hasnans

Return if I have any nans; enables various perf speedups.

pandas.Series.iat

property Series.iat

Access a single value for a row/column pair by integer position.

Similar to iloc, in that both provide integer-based lookups. Use iat if you only need to get or set a single value in a DataFrame or Series.

Raises

IndexError When integer position is out of bounds.

See also:

[DataFrame.at](#) Access a single value for a row/column label pair.

[DataFrame.loc](#) Access a group of rows and columns by label(s).

[DataFrame.iloc](#) Access a group of rows and columns by integer position(s).

Examples

```
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
...                      columns=['A', 'B', 'C'])
>>> df
   A    B    C
0  0    2    3
1  0    4    1
2  10   20   30
```

Get value at specified row/column pair

```
>>> df.iat[1, 2]
1
```

Set value at specified row/column pair

```
>>> df.iat[1, 2] = 10
>>> df.iat[1, 2]
10
```

Get value within a series

```
>>> df.loc[0].iat[1]
2
```

pandas.Series.iloc

property Series.iloc

Purely integer-location based indexing for selection by position.

.iloc[] is primarily integer position based (from 0 to length-1 of the axis), but may also be used with a boolean array.

Allowed inputs are:

- An integer, e.g. 5.
- A list or array of integers, e.g. [4, 3, 0].
- A slice object with ints, e.g. 1:7.
- A boolean array.
- A callable function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above). This is useful in method chains, when you don't have a reference to the calling object, but would like to base your selection on some value.

.iloc will raise IndexError if a requested indexer is out-of-bounds, except slice indexers which allow out-of-bounds indexing (this conforms with python/numpy slice semantics).

See more at [Selection by Position](#).

See also:

[DataFrame.iat](#) Fast integer location scalar accessor.

[DataFrame.loc](#) Purely label-location based indexer for selection by label.

[Series.iat](#) Purely integer-location based indexing for selection by position.

Examples

```
>>> mydict = [{ 'a': 1, 'b': 2, 'c': 3, 'd': 4},
...             { 'a': 100, 'b': 200, 'c': 300, 'd': 400},
...             { 'a': 1000, 'b': 2000, 'c': 3000, 'd': 4000 }]
>>> df = pd.DataFrame(mydict)
>>> df
     a      b      c      d
0    1      2      3      4
1   100    200    300    400
2  1000   2000   3000   4000
```

Indexing just the rows

With a scalar integer.

```
>>> type(df.iloc[0])
<class 'pandas.core.series.Series'>
>>> df.iloc[0]
a    1
b    2
c    3
d    4
Name: 0, dtype: int64
```

With a list of integers.

```
>>> df.iloc[[0]]
   a   b   c   d
0  1   2   3   4
>>> type(df.iloc[[0]])
<class 'pandas.core.frame.DataFrame'>
```

```
>>> df.iloc[[0, 1]]
   a     b     c     d
0  1     2     3     4
1  100   200   300   400
```

With a *slice* object.

```
>>> df.iloc[:3]
   a     b     c     d
0  1     2     3     4
1  100   200   300   400
2  1000  2000  3000  4000
```

With a boolean mask the same length as the index.

```
>>> df.iloc[[True, False, True]]
   a     b     c     d
0  1     2     3     4
2  1000  2000  3000  4000
```

With a callable, useful in method chains. The *x* passed to the `lambda` is the DataFrame being sliced. This selects the rows whose index label even.

```
>>> df.iloc[lambda x: x.index % 2 == 0]
   a     b     c     d
0  1     2     3     4
2  1000  2000  3000  4000
```

Indexing both axes

You can mix the indexer types for the index and columns. Use `:` to select the entire axis.

With scalar integers.

```
>>> df.iloc[0, 1]
2
```

With lists of integers.

```
>>> df.iloc[[0, 2], [1, 3]]
      b      d
0    2     4
2  2000  4000
```

With *slice* objects.

```
>>> df.iloc[1:3, 0:3]
      a      b      c
1  100    200   300
2 1000   2000  3000
```

With a boolean array whose length matches the columns.

```
>>> df.iloc[:, [True, False, True, False]]
      a      c
0    1     3
1  100   300
2 1000  3000
```

With a callable function that expects the Series or DataFrame.

```
>>> df.iloc[:, lambda df: [0, 2]]
      a      c
0    1     3
1  100   300
2 1000  3000
```

pandas.Series.index

Series.index

The index (axis labels) of the Series.

pandas.Series.is_monotonic

property Series.is_monotonic

Return boolean if values in the object are monotonic_increasing.

Returns

bool

pandas.Series.is_monotonic_decreasing

property Series.is_monotonic_decreasing

Return boolean if values in the object are monotonic_decreasing.

Returns

bool

`pandas.Series.is_monotonic_increasing`

property `Series.is_monotonic_increasing`

Return boolean if values in the object are monotonic_increasing.

Returns

`bool`

`pandas.Series.is_unique`

property `Series.is_unique`

Return boolean if values in the object are unique.

Returns

`bool`

`pandas.Series.loc`

property `Series.loc`

Access a group of rows and columns by label(s) or a boolean array.

`.loc[]` is primarily label based, but may also be used with a boolean array.

Allowed inputs are:

- A single label, e.g. 5 or 'a', (note that 5 is interpreted as a *label* of the index, and **never** as an integer position along the index).
- A list or array of labels, e.g. ['a', 'b', 'c'].
- A slice object with labels, e.g. 'a':'f'.

Warning: Note that contrary to usual python slices, **both** the start and the stop are included

- A boolean array of the same length as the axis being sliced, e.g. [True, False, True].
- A callable function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above)

See more at [Selection by Label](#)

Raises

KeyError If any items are not found.

See also:

`DataFrame.at` Access a single value for a row/column label pair.

`DataFrame.iloc` Access group of rows and columns by integer position(s).

`DataFrame.xs` Returns a cross-section (row(s) or column(s)) from the Series/DataFrame.

`Series.loc` Access group of values using labels.

Examples

Getting values

```
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
...                     index=['cobra', 'viper', 'sidewinder'],
...                     columns=['max_speed', 'shield'])
>>> df
   max_speed  shield
cobra         1        2
viper         4        5
sidewinder    7        8
```

Single label. Note this returns the row as a Series.

```
>>> df.loc['viper']
max_speed    4
shield       5
Name: viper, dtype: int64
```

List of labels. Note using [] returns a DataFrame.

```
>>> df.loc[['viper', 'sidewinder']]
   max_speed  shield
viper         4        5
sidewinder    7        8
```

Single label for row and column

```
>>> df.loc['cobra', 'shield']
2
```

Slice with labels for row and single label for column. As mentioned above, note that both the start and stop of the slice are included.

```
>>> df.loc['cobra':'viper', 'max_speed']
cobra    1
viper    4
Name: max_speed, dtype: int64
```

Boolean list with the same length as the row axis

```
>>> df.loc[[False, False, True]]
max_speed  shield
sidewinder    7        8
```

Conditional that returns a boolean Series

```
>>> df.loc[df['shield'] > 6]
max_speed  shield
sidewinder    7        8
```

Conditional that returns a boolean Series with column labels specified

```
>>> df.loc[df['shield'] > 6, ['max_speed']]
max_speed
sidewinder    7
```

Callable that returns a boolean Series

```
>>> df.loc[lambda df: df['shield'] == 8]
      max_speed  shield
sidewinder          7       8
```

Setting values

Set value for all items matching the list of labels

```
>>> df.loc[['viper', 'sidewinder'], ['shield']] = 50
>>> df
      max_speed  shield
cobra           1       2
viper           4      50
sidewinder       7      50
```

Set value for an entire row

```
>>> df.loc['cobra'] = 10
>>> df
      max_speed  shield
cobra          10      10
viper           4      50
sidewinder       7      50
```

Set value for an entire column

```
>>> df.loc[:, 'max_speed'] = 30
>>> df
      max_speed  shield
cobra          30      10
viper           30      50
sidewinder       30      50
```

Set value for rows matching callable condition

```
>>> df.loc[df['shield'] > 35] = 0
>>> df
      max_speed  shield
cobra          30      10
viper            0       0
sidewinder        0       0
```

Getting values on a DataFrame with an index that has integer labels

Another example using integers for the index

```
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
...                   index=[7, 8, 9], columns=['max_speed', 'shield'])
>>> df
      max_speed  shield
7             1       2
8             4       5
9             7       8
```

Slice with integer labels for rows. As mentioned above, note that both the start and stop of the slice are included.

```
>>> df.loc[7:9]
      max_speed  shield
7            1        2
8            4        5
9            7        8
```

Getting values with a MultiIndex

A number of examples using a DataFrame with a MultiIndex

```
>>> tuples = [
...     ('cobra', 'mark i'), ('cobra', 'mark ii'),
...     ('sidewinder', 'mark i'), ('sidewinder', 'mark ii'),
...     ('viper', 'mark ii'), ('viper', 'mark iii')
... ]
>>> index = pd.MultiIndex.from_tuples(tuples)
>>> values = [[12, 2], [0, 4], [10, 20],
...             [1, 4], [7, 1], [16, 36]]
>>> df = pd.DataFrame(values, columns=['max_speed', 'shield'], index=index)
>>> df
              max_speed  shield
cobra    mark i       12      2
          mark ii       0      4
sidewinder mark i       10     20
          mark ii       1      4
viper    mark ii       7      1
          mark iii      16     36
```

Single label. Note this returns a DataFrame with a single index.

```
>>> df.loc['cobra']
      max_speed  shield
mark i       12      2
mark ii       0      4
```

Single index tuple. Note this returns a Series.

```
>>> df.loc[('cobra', 'mark ii')]
max_speed    0
shield      4
Name: (cobra, mark ii), dtype: int64
```

Single label for row and column. Similar to passing in a tuple, this returns a Series.

```
>>> df.loc['cobra', 'mark i']
max_speed    12
shield      2
Name: (cobra, mark i), dtype: int64
```

Single tuple. Note using [[]] returns a DataFrame.

```
>>> df.loc[[('cobra', 'mark ii')]]
      max_speed  shield
cobra mark ii       0      4
```

Single tuple for the index with a single label for the column

```
>>> df.loc[('cobra', 'mark i'), 'shield']
2
```

Slice from index tuple to single label

```
>>> df.loc[('cobra', 'mark i'):'viper']
           max_speed  shield
cobra      mark i        12      2
              mark ii       0      4
sidewinder mark i        10     20
              mark ii        1      4
viper      mark ii        7      1
              mark iii       16     36
```

Slice from index tuple to index tuple

```
>>> df.loc[('cobra', 'mark i'):(('viper', 'mark ii'))]
           max_speed  shield
cobra      mark i        12      2
              mark ii       0      4
sidewinder mark i        10     20
              mark ii        1      4
viper      mark ii        7      1
```

pandas.Series.nbytes

property Series.nbytes

Return the number of bytes in the underlying data.

pandas.Series.ndim

property Series.ndim

Number of dimensions of the underlying data, by definition 1.

pandas.Series.shape

property Series.shape

Return a tuple of the shape of the underlying data.

pandas.Series.size

property Series.size

Return the number of elements in the underlying data.

pandas.Series.values**property Series.values**

Return Series as ndarray or ndarray-like depending on the dtype.

Warning: We recommend using `Series.array` or `Series.to_numpy()`, depending on whether you need a reference to the underlying data or a NumPy array.

Returns

`numpy.ndarray` or `ndarray-like`

See also:

`Series.array` Reference to the underlying data.

`Series.to_numpy` A NumPy array representing the underlying data.

Examples

```
>>> pd.Series([1, 2, 3]).values
array([1, 2, 3])
```

```
>>> pd.Series(list('aabc')).values
array(['a', 'a', 'b', 'c'], dtype=object)
```

```
>>> pd.Series(list('aabc')).astype('category').values
[a, a, b, c]
Categories (3, object): [a, b, c]
```

Timezone aware datetime data is converted to UTC:

```
>>> pd.Series(pd.date_range('20130101', periods=3,
...                         tz='US/Eastern')).values
array(['2013-01-01T05:00:00.000000000',
       '2013-01-02T05:00:00.000000000',
       '2013-01-03T05:00:00.000000000'], dtype='datetime64[ns]')
```

<code>empty</code>	
<code>name</code>	

Methods

<code>abs(self)</code>	Return a Series/DataFrame with absolute numeric value of each element.
<code>add(self, other[, level, fill_value, axis])</code>	Return Addition of series and other, element-wise (binary operator <code>add</code>).
<code>add_prefix(self, prefix)</code>	Prefix labels with string <code>prefix</code> .
<code>add_suffix(self, suffix)</code>	Suffix labels with string <code>suffix</code> .

Continued on next page

Table 29 – continued from previous page

<code>agg(self, func[, axis])</code>	Aggregate using one or more operations over the specified axis.
<code>aggregate(self, func[, axis])</code>	Aggregate using one or more operations over the specified axis.
<code>align(self, other[, join, axis, level, ...])</code>	Align two objects on their axes with the specified join method.
<code>all(self[, axis, bool_only, skipna, level])</code>	Return whether all elements are True, potentially over an axis.
<code>any(self[, axis, bool_only, skipna, level])</code>	Return whether any element is True, potentially over an axis.
<code>append(self, to_append[, ignore_index, ...])</code>	Concatenate two or more Series.
<code>apply(self, func[, convert_dtype, args])</code>	Invoke function on values of Series.
<code>argmax(self[, axis, skipna])</code>	Return an ndarray of the maximum argument indexer.
<code>argmin(self[, axis, skipna])</code>	Return a ndarray of the minimum argument indexer.
<code>argsort(self[, axis, kind, order])</code>	Override ndarray.argsort.
<code>asfreq(self, freq[, method, fill_value])</code>	Convert TimeSeries to specified frequency.
<code>asof(self, where[, subset])</code>	Return the last row(s) without any NaNs before where.
<code>astype(self, dtype, copy, errors)</code>	Cast a pandas object to a specified dtype <code>dtype</code> .
<code>at_time(self, time, asof[, axis])</code>	Select values at particular time of day (e.g.
<code>autocorr(self[, lag])</code>	Compute the lag-N autocorrelation.
<code>between(self, left, right[, inclusive])</code>	Return boolean Series equivalent to <code>left <= series <= right</code> .
<code>between_time(self, start_time, end_time, ...)</code>	Select values between particular times of the day (e.g., 9:00-9:30 AM).
<code>bfill(self[, axis, limit, downcast])</code>	Synonym for <code>DataFrame.fillna()</code> with <code>method='bfill'</code> .
<code>bool(self)</code>	Return the bool of a single element PandasObject.
<code>cat</code>	alias of <code>pandas.core.arrays.categorical.CategoricalAccessor</code>
<code>clip(self[, lower, upper, axis])</code>	Trim values at input threshold(s).
<code>combine(self, other, func[, fill_value])</code>	Combine the Series with a Series or scalar according to <code>func</code> .
<code>combine_first(self, other)</code>	Combine Series values, choosing the calling Series's values first.
<code>convert_dtypes(self, infer_objects, ...)</code>	Convert columns to best possible dtypes using dtypes supporting <code>pd.NA</code> .
<code>copy(self, deep)</code>	Make a copy of this object's indices and data.
<code>corr(self, other[, method, min_periods])</code>	Compute correlation with <code>other</code> Series, excluding missing values.
<code>count(self[, level])</code>	Return number of non-NA/null observations in the Series.
<code>cov(self, other[, min_periods])</code>	Compute covariance with Series, excluding missing values.
<code>cummax(self[, axis, skipna])</code>	Return cumulative maximum over a DataFrame or Series axis.
<code>cummin(self[, axis, skipna])</code>	Return cumulative minimum over a DataFrame or Series axis.
<code>cumprod(self[, axis, skipna])</code>	Return cumulative product over a DataFrame or Series axis.

Continued on next page

Table 29 – continued from previous page

<code>cumsum(self[, axis, skipna])</code>	Return cumulative sum over a DataFrame or Series axis.
<code>describe(self[, percentiles, include, exclude])</code>	Generate descriptive statistics.
<code>diff(self[, periods])</code>	First discrete difference of element.
<code>div(self, other[, level, fill_value, axis])</code>	Return Floating division of series and other, element-wise (binary operator <i>truediv</i>).
<code>divide(self, other[, level, fill_value, axis])</code>	Return Floating division of series and other, element-wise (binary operator <i>truediv</i>).
<code>divmod(self, other[, level, fill_value, axis])</code>	Return Integer division and modulo of series and other, element-wise (binary operator <i>divmod</i>).
<code>dot(self, other)</code>	Compute the dot product between the Series and the columns of other.
<code>drop(self[, labels, axis, index, columns, ...])</code>	Return Series with specified index labels removed.
<code>drop_duplicates(self[, keep, inplace])</code>	Return Series with duplicate values removed.
<code>droplevel(self, level[, axis])</code>	Return DataFrame with requested index / column level(s) removed.
<code>dropna(self[, axis, inplace, how])</code>	Return a new Series with missing values removed.
<code>dt</code>	alias of <code>pandas.core.indexes.accessors.CombinedDatetimelikeProperties</code>
<code>duplicated(self[, keep])</code>	Indicate duplicate Series values.
<code>eq(self, other[, level, fill_value, axis])</code>	Return Equal to of series and other, element-wise (binary operator <i>eq</i>).
<code>equals(self, other)</code>	Test whether two objects contain the same elements.
<code>ewm(self[, com, span, halflife, alpha, ...])</code>	Provide exponential weighted functions.
<code>expanding(self[, min_periods, center, axis])</code>	Provide expanding transformations.
<code>explode(self)</code>	Transform each element of a list-like to a row, replicating the index values.
<code>factorize(self[, sort, na_sentinel])</code>	Encode the object as an enumerated type or categorical variable.
<code>ffill(self[, axis, limit, downcast])</code>	Synonym for <code>DataFrame.fillna()</code> with method='ffill'.
<code>fillna(self[, value, method, axis, inplace, ...])</code>	Fill NA/NaN values using the specified method.
<code>filter(self[, items, axis])</code>	Subset the dataframe rows or columns according to the specified index labels.
<code>first(self, offset)</code>	Method to subset initial periods of time series data based on a date offset.
<code>first_valid_index(self)</code>	Return index for first non-NA/null value.
<code>floordiv(self, other[, level, fill_value, axis])</code>	Return Integer division of series and other, element-wise (binary operator <i>floordiv</i>).
<code>ge(self, other[, level, fill_value, axis])</code>	Return Greater than or equal to of series and other, element-wise (binary operator <i>ge</i>).
<code>get(self, key[, default])</code>	Get item from object for given key (ex: DataFrame column).
<code>groupby(self[, by, axis, level])</code>	Group Series using a mapper or by a Series of columns.
<code>gt(self, other[, level, fill_value, axis])</code>	Return Greater than of series and other, element-wise (binary operator <i>gt</i>).
<code>head(self, n)</code>	Return the first <i>n</i> rows.
<code>hist(self[, by, ax, grid, xlabelsize, xrot, ...])</code>	Draw histogram of the input series using matplotlib.
<code>idxmax(self[, axis, skipna])</code>	Return the row label of the maximum value.

Continued on next page

Table 29 – continued from previous page

<code>idxmin(self[, axis, skipna])</code>	Return the row label of the minimum value.
<code>infer_objects(self)</code>	Attempt to infer better dtypes for object columns.
<code>interpolate(self[, method, axis, limit, ...])</code>	Interpolate values according to different methods.
<code>isin(self, values)</code>	Check whether <i>values</i> are contained in Series.
<code>isna(self)</code>	Detect missing values.
<code>isnull(self)</code>	Detect missing values.
<code>item(self)</code>	Return the first element of the underlying data as a python scalar.
<code>items(self)</code>	Lazily iterate over (index, value) tuples.
<code>iteritems(self)</code>	Lazily iterate over (index, value) tuples.
<code>keys(self)</code>	Return alias for index.
<code>kurt(self[, axis, skipna, level, numeric_only])</code>	Return unbiased kurtosis over requested axis.
<code>kurtosis(self[, axis, skipna, level, ...])</code>	Return unbiased kurtosis over requested axis.
<code>last(self, offset)</code>	Method to subset final periods of time series data based on a date offset.
<code>last_valid_index(self)</code>	Return index for last non-NA/null value.
<code>le(self, other[, level, fill_value, axis])</code>	Return Less than or equal to of series and other, element-wise (binary operator <i>le</i>).
<code>lt(self, other[, level, fill_value, axis])</code>	Return Less than of series and other, element-wise (binary operator <i>lt</i>).
<code>mad(self[, axis, skipna, level])</code>	Return the mean absolute deviation of the values for the requested axis.
<code>map(self, arg[, na_action])</code>	Map values of Series according to input correspondence.
<code>mask(self, cond[, other, inplace, axis, ...])</code>	Replace values where the condition is True.
<code>max(self[, axis, skipna, level, numeric_only])</code>	Return the maximum of the values for the requested axis.
<code>mean(self[, axis, skipna, level, numeric_only])</code>	Return the mean of the values for the requested axis.
<code>median(self[, axis, skipna, level, numeric_only])</code>	Return the median of the values for the requested axis.
<code>memory_usage(self[, index, deep])</code>	Return the memory usage of the Series.
<code>min(self[, axis, skipna, level, numeric_only])</code>	Return the minimum of the values for the requested axis.
<code>mod(self, other[, level, fill_value, axis])</code>	Return Modulo of series and other, element-wise (binary operator <i>mod</i>).
<code>mode(self[, dropna])</code>	Return the mode(s) of the dataset.
<code>mul(self, other[, level, fill_value, axis])</code>	Return Multiplication of series and other, element-wise (binary operator <i>mul</i>).
<code>multiply(self, other[, level, fill_value, axis])</code>	Return Multiplication of series and other, element-wise (binary operator <i>mul</i>).
<code>ne(self, other[, level, fill_value, axis])</code>	Return Not equal to of series and other, element-wise (binary operator <i>ne</i>).
<code>nlargest(self[, n, keep])</code>	Return the largest <i>n</i> elements.
<code>notna(self)</code>	Detect existing (non-missing) values.
<code>notnull(self)</code>	Detect existing (non-missing) values.
<code>nsmallest(self[, n, keep])</code>	Return the smallest <i>n</i> elements.
<code>nunique(self[, dropna])</code>	Return number of unique elements in the object.
<code>pct_change(self[, periods, fill_method, ...])</code>	Percentage change between the current and a prior element.
<code>pipe(self, func, *args, **kwargs)</code>	Apply func(self, *args, **kwargs).

Continued on next page

Table 29 – continued from previous page

<code>plot</code>	alias of <code>pandas.plotting._core.PlotAccessor</code>
<code>pop(self, item)</code>	Return item and drop from frame.
<code>pow(self, other[, level, fill_value, axis])</code>	Return Exponential power of series and other, element-wise (binary operator <code>pow</code>).
<code>prod(self[, axis, skipna, level, ...])</code>	Return the product of the values for the requested axis.
<code>product(self[, axis, skipna, level, ...])</code>	Return the product of the values for the requested axis.
<code>quantile(self[, q, interpolation])</code>	Return value at the given quantile.
<code>radd(self, other[, level, fill_value, axis])</code>	Return Addition of series and other, element-wise (binary operator <code>radd</code>).
<code>rank(self[, axis])</code>	Compute numerical data ranks (1 through n) along axis.
<code>ravel(self[, order])</code>	Return the flattened underlying data as an ndarray.
<code>rdiv(self, other[, level, fill_value, axis])</code>	Return Floating division of series and other, element-wise (binary operator <code>rtruediv</code>).
<code>rdivmod(self, other[, level, fill_value, axis])</code>	Return Integer division and modulo of series and other, element-wise (binary operator <code>rdivmod</code>).
<code>reindex(self[, index])</code>	Conform Series to new index with optional filling logic.
<code>reindex_like(self, other, method, ...[, ...])</code>	Return an object with matching indices as other object.
<code>rename(self[, index, axis, copy, inplace, ...])</code>	Alter Series index labels or name.
<code>rename_axis(self[, mapper, index, columns, ...])</code>	Set the name of the axis for the index or columns.
<code>reorder_levels(self, order)</code>	Rearrange index levels using input order.
<code>repeat(self, repeats[, axis])</code>	Repeat elements of a Series.
<code>replace(self[, to_replace, value, inplace, ...])</code>	Replace values given in <code>to_replace</code> with <code>value</code> .
<code>resample(self, rule[, axis, loffset, on, level])</code>	Resample time-series data.
<code>reset_index(self[, level, drop, name, inplace])</code>	Generate a new DataFrame or Series with the index reset.
<code>rfloordiv(self, other[, level, fill_value, axis])</code>	Return Integer division of series and other, element-wise (binary operator <code>rfloordiv</code>).
<code>rmod(self, other[, level, fill_value, axis])</code>	Return Modulo of series and other, element-wise (binary operator <code>rmod</code>).
<code>rmul(self, other[, level, fill_value, axis])</code>	Return Multiplication of series and other, element-wise (binary operator <code>rmul</code>).
<code>rolling(self, window[, min_periods, center, ...])</code>	Provide rolling window calculations.
<code>round(self[, decimals])</code>	Round each value in a Series to the given number of decimals.
<code>rpow(self, other[, level, fill_value, axis])</code>	Return Exponential power of series and other, element-wise (binary operator <code>rpow</code>).
<code>rsub(self, other[, level, fill_value, axis])</code>	Return Subtraction of series and other, element-wise (binary operator <code>rsub</code>).
<code>rtruediv(self, other[, level, fill_value, axis])</code>	Return Floating division of series and other, element-wise (binary operator <code>rtruediv</code>).
<code>sample(self[, n, frac, replace, weights, ...])</code>	Return a random sample of items from an axis of object.
<code>searchsorted(self, value[, side, sorter])</code>	Find indices where elements should be inserted to maintain order.

Continued on next page

Table 29 – continued from previous page

<code>sem(self[, axis, skipna, level, ddof, ...])</code>	Return unbiased standard error of the mean over requested axis.
<code>set_axis(self, labels[, axis, inplace])</code>	Assign desired index to given axis.
<code>shift(self[, periods, freq, axis, fill_value])</code>	Shift index by desired number of periods with an optional time <i>freq</i> .
<code>skew(self[, axis, skipna, level, numeric_only])</code>	Return unbiased skew over requested axis.
<code>slice_shift(self, periods[, axis])</code>	Equivalent to <code>shift</code> without copying data.
<code>sort_index(self[, axis, level, ascending, ...])</code>	Sort Series by index labels.
<code>sort_values(self[, axis, ascending, ...])</code>	Sort by the values.
<code>sparse</code>	alias of <code>pandas.core.arrays.sparse.accessor.SparseAccessor</code>
<code>squeeze(self[, axis])</code>	Squeeze 1 dimensional axis objects into scalars.
<code>std(self[, axis, skipna, level, ddof, ...])</code>	Return sample standard deviation over requested axis.
<code>str</code>	alias of <code>pandas.core.strings.StringMethods</code>
<code>sub(self, other[, level, fill_value, axis])</code>	Return Subtraction of series and other, element-wise (binary operator <code>sub</code>).
<code>subtract(self, other[, level, fill_value, axis])</code>	Return Subtraction of series and other, element-wise (binary operator <code>sub</code>).
<code>sum(self[, axis, skipna, level, ...])</code>	Return the sum of the values for the requested axis.
<code>swapaxes(self, axis1, axis2[, copy])</code>	Interchange axes and swap values axes appropriately.
<code>swaplevel(self[, i, j, copy])</code>	Swap levels <i>i</i> and <i>j</i> in a <code>MultiIndex</code> .
<code>tail(self, n)</code>	Return the last <i>n</i> rows.
<code>take(self, indices[, axis, is_copy])</code>	Return the elements in the given <i>positional</i> indices along an axis.
<code>to_clipboard(self, excel, sep, ...)</code>	Copy object to the system clipboard.
<code>to_csv(self, path_or_buf, pathlib.Path, ...)</code>	Write object to a comma-separated values (csv) file.
<code>to_dict(self[, into])</code>	Convert Series to {label -> value} dict or dict-like object.
<code>to_excel(self, excel_writer[, sheet_name, ...])</code>	Write object to an Excel sheet.
<code>to_frame(self[, name])</code>	Convert Series to DataFrame.
<code>to_hdf(self, path_or_buf, key, mode, ...[, ...])</code>	Write the contained data to an HDF5 file using HDFStore.
<code>to_json(self, path_or_buf, pathlib.Path, ...)</code>	Convert the object to a JSON string.
<code>to_latex(self[, buf, columns, col_space, ...])</code>	Render object to a LaTeX tabular, longtable, or nested table/tabular.
<code>to_list(self)</code>	Return a list of the values.
<code>to_markdown(self, buf, NoneType] = None, ...)</code>	Print Series in Markdown-friendly format.
<code>to_numpy(self[, dtype, copy, na_value])</code>	A NumPy ndarray representing the values in this Series or Index.
<code>to_period(self[, freq, copy])</code>	Convert Series from DatetimeIndex to PeriodIndex with desired frequency (inferred from index if not passed).
<code>to_pickle(self, path, compression, ...)</code>	Pickle (serialize) object to file.
<code>to_sql(self, name, con[, schema, ...])</code>	Write records stored in a DataFrame to a SQL database.
<code>to_string(self[, buf, na_rep, float_format, ...])</code>	Render a string representation of the Series.
<code>to_timestamp(self[, freq, how, copy])</code>	Cast to DatetimeIndex of Timestamps, at <i>beginning</i> of period.
<code>to_xarray(self)</code>	Return an xarray object from the pandas object.

Continued on next page

Table 29 – continued from previous page

<code>tolist(self)</code>	Return a list of the values.
<code>transform(self, func[, axis])</code>	Call <code>func</code> on <code>self</code> producing a Series with transformed values.
<code>transpose(self, *args, **kwargs)</code>	Return the transpose, which is by definition <code>self</code> .
<code>truediv(self, other[, level, fill_value, axis])</code>	Return Floating division of series and other, element-wise (binary operator <code>truediv</code>).
<code>truncate(self[, before, after, axis])</code>	Truncate a Series or DataFrame before and after some index value.
<code>tshift(self, periods[, freq, axis])</code>	Shift the time index, using the index's frequency if available.
<code>tz_convert(self, tz[, axis, level])</code>	Convert tz-aware axis to target time zone.
<code>tz_localize(self, tz[, axis, level, ambiguous])</code>	Localize tz-naive index of a Series or DataFrame to target time zone.
<code>unique(self)</code>	Return unique values of Series object.
<code>unstack(self[, level, fill_value])</code>	Unstack, a.k.a.
<code>update(self, other)</code>	Modify Series in place using non-NA values from passed Series.
<code>value_counts(self[, normalize, sort, ...])</code>	Return a Series containing counts of unique values.
<code>var(self[, axis, skipna, level, ddof, ...])</code>	Return unbiased variance over requested axis.
<code>view(self[, dtype])</code>	Create a new view of the Series.
<code>where(self, cond[, other, inplace, axis, ...])</code>	Replace values where the condition is False.
<code>xs(self, key[, axis, level])</code>	Return cross-section from the Series/DataFrame.

pandas.Series.abs

`Series.abs (self: ~FrameOrSeries) → ~FrameOrSeries`

Return a Series/DataFrame with absolute numeric value of each element.

This function only applies to elements that are all numeric.

Returns

`abs` Series/DataFrame containing the absolute value of each element.

See also:

`numpy.absolute` Calculate the absolute value element-wise.

Notes

For complex inputs, $1.2 + 1j$, the absolute value is $\sqrt{a^2 + b^2}$.

Examples

Absolute numeric values in a Series.

```
>>> s = pd.Series([-1.10, 2, -3.33, 4])
>>> s.abs()
0    1.10
1    2.00
2    3.33
3    4.00
dtype: float64
```

Absolute numeric values in a Series with complex numbers.

```
>>> s = pd.Series([1.2 + 1j])
>>> s.abs()
0    1.56205
dtype: float64
```

Absolute numeric values in a Series with a Timedelta element.

```
>>> s = pd.Series([pd.Timedelta('1 days')])
>>> s.abs()
0    1 days
dtype: timedelta64[ns]
```

Select rows with data closest to certain value using argsort (from StackOverflow).

```
>>> df = pd.DataFrame({
...     'a': [4, 5, 6, 7],
...     'b': [10, 20, 30, 40],
...     'c': [100, 50, -30, -50]
... })
>>> df
   a    b    c
0  4   10  100
1  5   20   50
2  6   30  -30
3  7   40  -50
>>> df.loc[(df.c - 43).abs().argsort()]
   a    b    c
1  5   20   50
0  4   10  100
2  6   30  -30
3  7   40  -50
```

pandas.Series.add

`Series.add(self, other, level=None, fill_value=None, axis=0)`

Return Addition of series and other, element-wise (binary operator *add*).

Equivalent to `series + other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

`Series.radd`

Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64
```

`pandas.Series.add_prefix`

`Series.add_prefix(self: ~FrameOrSeries, prefix: str) → ~FrameOrSeries`
Prefix labels with string *prefix*.

For Series, the row labels are prefixed. For DataFrame, the column labels are prefixed.

Parameters

`prefix` [str] The string to add before each label.

Returns

`Series or DataFrame` New Series or DataFrame with updated labels.

See also:

`Series.add_suffix` Suffix row labels with string *suffix*.

`DataFrame.add_suffix` Suffix column labels with string *suffix*.

Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64
```

```
>>> s.add_prefix('item_')
item_0    1
item_1    2
item_2    3
item_3    4
dtype: int64
```

```
>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
>>> df
   A    B
0  1    3
1  2    4
2  3    5
3  4    6
```

```
>>> df.add_prefix('col_')
      col_A    col_B
0         1        3
1         2        4
2         3        5
3         4        6
```

pandas.Series.add_suffix

`Series.add_suffix(self: ~FrameOrSeries, suffix: str) → ~FrameOrSeries`
 Suffix labels with string *suffix*.

For Series, the row labels are suffixed. For DataFrame, the column labels are suffixed.

Parameters

`suffix` [str] The string to add after each label.

Returns

`Series or DataFrame` New Series or DataFrame with updated labels.

See also:

`Series.add_prefix` Prefix row labels with string *prefix*.

`DataFrame.add_prefix` Prefix column labels with string *prefix*.

Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64
```

```
>>> s.add_suffix('_item')
0_item    1
1_item    2
2_item    3
3_item    4
dtype: int64
```

```
>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
>>> df
   A    B
0  1    3
1  2    4
2  3    5
3  4    6
```

```
>>> df.add_suffix('_col')
      A_col  B_col
0        1      3
1        2      4
2        3      5
3        4      6
```

`pandas.Series.agg`

`Series.agg(self, func, axis=0, *args, **kwargs)`

Aggregate using one or more operations over the specified axis.

New in version 0.20.0.

Parameters

func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a Series or when passed to Series.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. [`np.sum`, 'mean']
- dict of axis labels -> functions, function names or list of such.

axis [{0 or 'index'}] Parameter needed for compatibility with DataFrame.

***args** Positional arguments to pass to *func*.

****kwargs** Keyword arguments to pass to *func*.

Returns

scalar, Series or DataFrame The return can be:

- scalar : when Series.agg is called with single function
- Series : when DataFrame.agg is called with a single function
- DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

See also:

`Series.apply` Invoke function on a Series.

`Series.transform` Transform function producing a Series with like indexes.

Notes

agg is an alias for *aggregate*. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64
```

```
>>> s.agg('min')
1
```

```
>>> s.agg(['min', 'max'])
min    1
max    4
dtype: int64
```

pandas.Series.aggregate

`Series.aggregate(self, func, axis=0, *args, **kwargs)`

Aggregate using one or more operations over the specified axis.

New in version 0.20.0.

Parameters

func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a Series or when passed to Series.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. [np.sum, 'mean']
- dict of axis labels -> functions, function names or list of such.

axis [{0 or 'index'}]) Parameter needed for compatibility with DataFrame.

***args** Positional arguments to pass to *func*.

****kwargs** Keyword arguments to pass to *func*.

Returns

scalar, Series or DataFrame The return can be:

- scalar : when Series.agg is called with single function
- Series : when DataFrame.agg is called with a single function
- DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

See also:

[`Series.apply`](#) Invoke function on a Series.

[`Series.transform`](#) Transform function producing a Series with like indexes.

Notes

agg is an alias for *aggregate*. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64
```

```
>>> s.agg('min')
1
```

```
>>> s.agg(['min', 'max'])
min    1
max    4
dtype: int64
```

pandas.Series.align

`Series.align(self, other, join='outer', axis=None, level=None, copy=True, fill_value=None, method=None, limit=None, fill_axis=0, broadcast_axis=None)`
Align two objects on their axes with the specified join method.

Join method is specified for each axis Index.

Parameters

other [DataFrame or Series]

join [{‘outer’, ‘inner’, ‘left’, ‘right’}], default ‘outer’]

axis [allowed axis of the other object, default None] Align on index (0), columns (1), or both (None).

level [int or level name, default None] Broadcast across a level, matching Index values on the passed MultiIndex level.

copy [bool, default True] Always returns new objects. If copy=False and no reindexing is required then original objects are returned.

fill_value [scalar, default np.NaN] Value to use for missing values. Defaults to NaN, but can be any “compatible” value.

method [{‘backfill’, ‘bfill’, ‘pad’, ‘ffill’, None}, default None] Method to use for filling holes in reindexed Series:

- pad / ffill: propagate last valid observation forward to next valid.
- backfill / bfill: use NEXT valid observation to fill gap.

limit [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

fill_axis [{0 or ‘index’}, default 0] Filling axis, method and limit.

broadcast_axis [{0 or ‘index’}, default None] Broadcast values along this axis, if aligning two objects of different dimensions.

Returns

(left, right) [(Series, type of other)] Aligned objects.

pandas.Series.all

Series.all (*self, axis=0, bool_only=None, skipna=True, level=None, **kwargs*)

Return whether all elements are True, potentially over an axis.

Returns True unless there at least one element within a series or along a Dataframe axis that is False or equivalent (e.g. zero or empty).

Parameters

axis [{0 or ‘index’, 1 or ‘columns’, None}, default 0] Indicate which axis or axes should be reduced.

- 0 / ‘index’ : reduce the index, return a Series whose index is the original column labels.
- 1 / ‘columns’ : reduce the columns, return a Series whose index is the original index.
- None : reduce all axes, return a scalar.

bool_only [bool, default None] Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.

skipna [bool, default True] Exclude NA/null values. If the entire row/column is NA and skipna is True, then the result will be True, as for an empty row/column. If skipna is False, then NA are treated as True, because these are not equal to zero.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

****kwargs** [any, default None] Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

scalar or Series If level is specified, then, Series is returned; otherwise, scalar is returned.

See also:

[**Series.all**](#) Return True if all elements are True.

[**DataFrame.any**](#) Return True if one (or more) elements are True.

Examples

Series

```
>>> pd.Series([True, True]).all()
True
>>> pd.Series([True, False]).all()
False
>>> pd.Series([]).all()
True
>>> pd.Series([np.nan]).all()
True
>>> pd.Series([np.nan]).all(skipna=False)
True
```

DataFrames

Create a dataframe from a dictionary.

```
>>> df = pd.DataFrame({'col1': [True, True], 'col2': [True, False]})
>>> df
   col1    col2
0  True    True
1  True   False
```

Default behaviour checks if column-wise values all return True.

```
>>> df.all()
   col1    True
   col2   False
dtype: bool
```

Specify `axis='columns'` to check if row-wise values all return True.

```
>>> df.all(axis='columns')
0    True
1   False
dtype: bool
```

Or `axis=None` for whether every value is True.

```
>>> df.all(axis=None)
False
```

pandas.Series.any

`Series.any(self, axis=0, bool_only=None, skipna=True, level=None, **kwargs)`

Return whether any element is True, potentially over an axis.

Returns False unless there at least one element within a series or along a Dataframe axis that is True or equivalent (e.g. non-zero or non-empty).

Parameters

`axis` [{0 or ‘index’, 1 or ‘columns’, None}, default 0] Indicate which axis or axes should be reduced.

- 0 / ‘index’ : reduce the index, return a Series whose index is the original column labels.

- 1 / ‘columns’ : reduce the columns, return a Series whose index is the original index.
- None : reduce all axes, return a scalar.

bool_only [bool, default None] Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.

skipna [bool, default True] Exclude NA/null values. If the entire row/column is NA and skipna is True, then the result will be False, as for an empty row/column. If skipna is False, then NA are treated as True, because these are not equal to zero.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

****kwargs** [any, default None] Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

scalar or Series If level is specified, then, Series is returned; otherwise, scalar is returned.

See also:

[numpy.any](#) Numpy version of this method.

[Series.any](#) Return whether any element is True.

[Series.all](#) Return whether all elements are True.

[DataFrame.any](#) Return whether any element is True over requested axis.

[DataFrame.all](#) Return whether all elements are True over requested axis.

Examples

Series

For Series input, the output is a scalar indicating whether any element is True.

```
>>> pd.Series([False, False]).any()
False
>>> pd.Series([True, False]).any()
True
>>> pd.Series([]).any()
False
>>> pd.Series([np.nan]).any()
False
>>> pd.Series([np.nan]).any(skipna=False)
True
```

DataFrame

Whether each column contains at least one True element (the default).

```
>>> df = pd.DataFrame({ "A": [1, 2], "B": [0, 2], "C": [0, 0] })
>>> df
   A  B  C
0  1  0  0
1  2  2  0
```

```
>>> df.any()
A      True
B      True
C    False
dtype: bool
```

Aggregating over the columns.

```
>>> df = pd.DataFrame({ "A": [True, False], "B": [1, 2] })
>>> df
   A   B
0  True  1
1  False  2
```

```
>>> df.any(axis='columns')
0      True
1      True
dtype: bool
```

```
>>> df = pd.DataFrame({ "A": [True, False], "B": [1, 0] })
>>> df
   A   B
0  True  1
1  False  0
```

```
>>> df.any(axis='columns')
0      True
1     False
dtype: bool
```

Aggregating over the entire DataFrame with axis=None.

```
>>> df.any(axis=None)
True
```

any for an empty DataFrame is an empty Series.

```
>>> pd.DataFrame([]).any()
Series([], dtype: bool)
```

pandas.Series.append

`Series.append(self, to_append, ignore_index=False, verify_integrity=False)`
Concatenate two or more Series.

Parameters

to_append [Series or list/tuple of Series] Series to append with self.
ignore_index [bool, default False] If True, do not use the index labels.
verify_integrity [bool, default False] If True, raise Exception on creating index with duplicates.

Returns

Series Concatenated Series.

See also:

`concat` General function to concatenate DataFrame or Series objects.

Notes

Iteratively appending to a Series can be more computationally intensive than a single concatenate. A better solution is to append values to a list and then concatenate the list with the original Series all at once.

Examples

```
>>> s1 = pd.Series([1, 2, 3])
>>> s2 = pd.Series([4, 5, 6])
>>> s3 = pd.Series([4, 5, 6], index=[3, 4, 5])
>>> s1.append(s2)
0    1
1    2
2    3
0    4
1    5
2    6
dtype: int64
```

```
>>> s1.append(s3)
0    1
1    2
2    3
3    4
4    5
5    6
dtype: int64
```

With `ignore_index` set to True:

```
>>> s1.append(s2, ignore_index=True)
0    1
1    2
2    3
3    4
4    5
5    6
dtype: int64
```

With `verify_integrity` set to True:

```
>>> s1.append(s2, verify_integrity=True)
Traceback (most recent call last):
...
ValueError: Indexes have overlapping values: [0, 1, 2]
```

`pandas.Series.apply`

`Series.apply(self, func, convert_dtype=True, args=(), **kwds)`

Invoke function on values of Series.

Can be ufunc (a NumPy function that applies to the entire Series) or a Python function that only works on single values.

Parameters

`func` [function] Python function or NumPy ufunc to apply.

`convert_dtype` [bool, default True] Try to find better dtype for elementwise function results.
If False, leave as dtype=object.

`args` [tuple] Positional arguments passed to func after the series value.

`**kwds` Additional keyword arguments passed to func.

Returns

`Series or DataFrame` If func returns a Series object the result will be a DataFrame.

See also:

`Series.map` For element-wise operations.

`Series.agg` Only perform aggregating type operations.

`Series.transform` Only perform transforming type operations.

Examples

Create a series with typical summer temperatures for each city.

```
>>> s = pd.Series([20, 21, 12],  
...                 index=['London', 'New York', 'Helsinki'])  
>>> s  
London      20  
New York    21  
Helsinki   12  
dtype: int64
```

Square the values by defining a function and passing it as an argument to `apply()`.

```
>>> def square(x):  
...     return x ** 2  
>>> s.apply(square)  
London      400  
New York    441  
Helsinki   144  
dtype: int64
```

Square the values by passing an anonymous function as an argument to `apply()`.

```
>>> s.apply(lambda x: x ** 2)  
London      400  
New York    441  
Helsinki   144  
dtype: int64
```

Define a custom function that needs additional positional arguments and pass these additional arguments using the `args` keyword.

```
>>> def subtract_custom_value(x, custom_value):
...     return x - custom_value
```

```
>>> s.apply(subtract_custom_value, args=(5,))
London      15
New York    16
Helsinki    7
dtype: int64
```

Define a custom function that takes keyword arguments and pass these arguments to `apply`.

```
>>> def add_custom_values(x, **kwargs):
...     for month in kwargs:
...         x += kwargs[month]
...     return x
```

```
>>> s.apply(add_custom_values, june=30, july=20, august=25)
London      95
New York    96
Helsinki    87
dtype: int64
```

Use a function from the Numpy library.

```
>>> s.apply(np.log)
London      2.995732
New York    3.044522
Helsinki    2.484907
dtype: float64
```

pandas.Series.argmax

`Series.argmax(self, axis=None, skipna=True, *args, **kwargs)`
Return an ndarray of the maximum argument indexer.

Parameters

`axis` [{None}] Dummy argument for consistency with Series.
`skipna` [bool, default True]

Returns

`numpy.ndarray` Indices of the maximum values.

See also:

`numpy.ndarray.argmax`

[pandas.Series.argmin](#)

`Series.argmin(self, axis=None, skipna=True, *args, **kwargs)`
Return a ndarray of the minimum argument indexer.

Parameters

axis [{None}] Dummy argument for consistency with Series.
skipna [bool, default True]

Returns

`numpy.ndarray`

See also:

[numpy.ndarray.argmax](#)

[pandas.Series.argsort](#)

`Series.argsort(self, axis=0, kind='quicksort', order=None)`
Override ndarray.argsort. Argsorts the value, omitting NA/null values, and places the result in the same locations as the non-NA values.

Parameters

axis [{0 or “index”}] Has no effect but is accepted for compatibility with numpy.
kind [{‘mergesort’, ‘quicksort’, ‘heapsort’}, default ‘quicksort’] Choice of sorting algorithm. See np.sort for more information. ‘mergesort’ is the only stable algorithm.
order [None] Has no effect but is accepted for compatibility with numpy.

Returns

`Series` Positions of values within the sort order with -1 indicating nan values.

See also:

[numpy.ndarray.argsort](#)

[pandas.Series.asfreq](#)

`Series.asfreq(self: ~FrameOrSeries, freq, method=None, how: Union[str, NoneType] = None, normalize: bool = False, fill_value=None) → ~FrameOrSeries`
Convert TimeSeries to specified frequency.

Optionally provide filling method to pad/backfill missing values.

Returns the original data conformed to a new index with the specified frequency. `resample` is more appropriate if an operation, such as summarization, is necessary to represent the data at the new frequency.

Parameters

freq [DateOffset or str]
method [{‘backfill’/‘bfill’, ‘pad’/‘ffill’}, default None] Method to use for filling holes in reindexed Series (note this does not fill NaNs that already were present):

- ‘pad’ / ‘ffill’: propagate last valid observation forward to next valid

- ‘backfill’ / ‘bfill’: use NEXT valid observation to fill.

how [{‘start’, ‘end’}, default end] For PeriodIndex only (see PeriodIndex.asfreq).

normalize [bool, default False] Whether to reset output index to midnight.

fill_value [scalar, optional] Value to use for missing values, applied during upsampling (note this does not fill NaNs that already were present).

Returns

converted [same type as caller]

See also:

[reindex](#)

Notes

To learn more about the frequency strings, please see [this link](#).

Examples

Start by creating a series with 4 one minute timestamps.

```
>>> index = pd.date_range('1/1/2000', periods=4, freq='T')
>>> series = pd.Series([0.0, None, 2.0, 3.0], index=index)
>>> df = pd.DataFrame({'s':series})
>>> df
          s
2000-01-01 00:00:00    0.0
2000-01-01 00:01:00    NaN
2000-01-01 00:02:00    2.0
2000-01-01 00:03:00    3.0
```

Upsample the series into 30 second bins.

```
>>> df.asfreq(freq='30S')
          s
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30    NaN
2000-01-01 00:01:00    NaN
2000-01-01 00:01:30    NaN
2000-01-01 00:02:00    2.0
2000-01-01 00:02:30    NaN
2000-01-01 00:03:00    3.0
```

Upsample again, providing a fill_value.

```
>>> df.asfreq(freq='30S', fill_value=9.0)
          s
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30    9.0
2000-01-01 00:01:00    NaN
2000-01-01 00:01:30    9.0
2000-01-01 00:02:00    2.0
2000-01-01 00:02:30    9.0
2000-01-01 00:03:00    3.0
```

Upsample again, providing a method.

```
>>> df.asfreq(freq='30S', method='bfill')
          s
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30    NaN
2000-01-01 00:01:00    NaN
2000-01-01 00:01:30    2.0
2000-01-01 00:02:00    2.0
2000-01-01 00:02:30    3.0
2000-01-01 00:03:00    3.0
```

pandas.Series.asof

`Series.asof(self, where, subset=None)`

Return the last row(s) without any NaNs before `where`.

The last row (for each element in `where`, if list) without any NaN is taken. In case of a `DataFrame`, the last row without NaN considering only the subset of columns (if not `None`)

If there is no good value, NaN is returned for a Series or a Series of NaN values for a DataFrame

Parameters

where [date or array-like of dates] Date(s) before which the last row(s) are returned.

subset [str or array-like of str, default `None`] For DataFrame, if not `None`, only use these columns to check for NaNs.

Returns

scalar, Series, or DataFrame The return can be:

- scalar : when `self` is a Series and `where` is a scalar
- Series: when `self` is a Series and `where` is an array-like, or when `self` is a DataFrame and `where` is a scalar
- DataFrame : when `self` is a DataFrame and `where` is an array-like

Return scalar, Series, or DataFrame.

See also:

`merge_asof` Perform an asof merge. Similar to left join.

Notes

Dates are assumed to be sorted. Raises if this is not the case.

Examples

A Series and a scalar *where*.

```
>>> s = pd.Series([1, 2, np.nan, 4], index=[10, 20, 30, 40])
>>> s
10    1.0
20    2.0
30    NaN
40    4.0
dtype: float64
```

```
>>> s.asof(20)
2.0
```

For a sequence *where*, a Series is returned. The first value is NaN, because the first element of *where* is before the first index value.

```
>>> s.asof([5, 20])
5      NaN
20    2.0
dtype: float64
```

Missing values are not considered. The following is 2.0, not NaN, even though NaN is at the index location for 30.

```
>>> s.asof(30)
2.0
```

Take all columns into consideration

```
>>> df = pd.DataFrame({'a': [10, 20, 30, 40, 50],
...                     'b': [None, None, None, None, 500]},
...                     index=pd.DatetimeIndex(['2018-02-27 09:01:00',
...                                         '2018-02-27 09:02:00',
...                                         '2018-02-27 09:03:00',
...                                         '2018-02-27 09:04:00',
...                                         '2018-02-27 09:05:00']))
>>> df.asof(pd.DatetimeIndex(['2018-02-27 09:03:30',
...                             '2018-02-27 09:04:30']))
           a    b
2018-02-27 09:03:30  NaN  NaN
2018-02-27 09:04:30  NaN  NaN
```

Take a single column into consideration

```
>>> df.asof(pd.DatetimeIndex(['2018-02-27 09:03:30',
...                             '2018-02-27 09:04:30']),
...             subset=['a'])
           a    b
2018-02-27 09:03:30  30.0  NaN
2018-02-27 09:04:30  40.0  NaN
```

pandas.Series.astype

`Series.astype(self: ~FrameOrSeries, dtype, copy: bool = True, errors: str = 'raise') → ~Frame-OrSeries`
Cast a pandas object to a specified dtype `dtype`.

Parameters

dtype [data type, or dict of column name -> data type] Use a numpy.dtype or Python type to cast entire pandas object to the same type. Alternatively, use `{col: dtype, ...}`, where col is a column label and dtype is a numpy.dtype or Python type to cast one or more of the DataFrame's columns to column-specific types.

copy [bool, default True] Return a copy when `copy=True` (be very careful setting `copy=False` as changes to values then may propagate to other pandas objects).

errors [{‘raise’, ‘ignore’}, default ‘raise’] Control raising of exceptions on invalid data for provided dtype.

- `raise` : allow exceptions to be raised
- `ignore` : suppress exceptions. On error return original object.

Returns

casted [same type as caller]

See also:

[to_datetime](#) Convert argument to datetime.

[to_timedelta](#) Convert argument to timedelta.

[to_numeric](#) Convert argument to a numeric type.

[numpy.ndarray.astype](#) Cast a numpy array to a specified type.

Examples

Create a DataFrame:

```
>>> d = {'col1': [1, 2], 'col2': [3, 4]}
>>> df = pd.DataFrame(data=d)
>>> df.dtypes
col1    int64
col2    int64
dtype: object
```

Cast all columns to int32:

```
>>> df.astype('int32').dtypes
col1    int32
col2    int32
dtype: object
```

Cast col1 to int32 using a dictionary:

```
>>> df.astype({'col1': 'int32'}).dtypes
col1    int32
col2    int64
dtype: object
```

Create a series:

```
>>> ser = pd.Series([1, 2], dtype='int32')
>>> ser
0    1
1    2
dtype: int32
>>> ser.astype('int64')
0    1
1    2
dtype: int64
```

Convert to categorical type:

```
>>> ser.astype('category')
0    1
1    2
dtype: category
Categories (2, int64): [1, 2]
```

Convert to ordered categorical type with custom ordering:

```
>>> cat_dtype = pd.api.types.CategoricalDtype(
...     categories=[2, 1], ordered=True)
>>> ser.astype(cat_dtype)
0    1
1    2
dtype: category
Categories (2, int64): [2 < 1]
```

Note that using `copy=False` and changing data on a new pandas object may propagate changes:

```
>>> s1 = pd.Series([1, 2])
>>> s2 = s1.astype('int64', copy=False)
>>> s2[0] = 10
>>> s1 # note that s1[0] has changed too
0    10
1    2
dtype: int64
```

pandas.Series.at_time

`Series.at_time(self: ~FrameOrSeries, time, asof: bool = False, axis=None) → ~FrameOrSeries`
Select values at particular time of day (e.g. 9:30AM).

Parameters

`time` [datetime.time or str]

`axis` [{0 or ‘index’, 1 or ‘columns’}, default 0] New in version 0.24.0.

Returns

`Series or DataFrame`

Raises

`TypeError` If the index is not a `DatetimeIndex`

See also:

`between_time` Select values between particular times of the day.

`first` Select initial periods of time series based on a date offset.

`last` Select final periods of time series based on a date offset.

`DatetimeIndex.indexer_at_time` Get just the index locations for values at particular time of the day.

Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='12H')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
          A
2018-04-09 00:00:00 1
2018-04-09 12:00:00 2
2018-04-10 00:00:00 3
2018-04-10 12:00:00 4
```

```
>>> ts.at_time('12:00')
          A
2018-04-09 12:00:00 2
2018-04-10 12:00:00 4
```

pandas.Series.autocorr

`Series.autocorr(self, lag=1)`

Compute the lag-N autocorrelation.

This method computes the Pearson correlation between the Series and its shifted self.

Parameters

`lag` [int, default 1] Number of lags to apply before performing autocorrelation.

Returns

`float` The Pearson correlation between self and self.shift(lag).

See also:

`Series.corr` Compute the correlation between two Series.

`Series.shift` Shift index by desired number of periods.

`DataFrame.corr` Compute pairwise correlation of columns.

`DataFrame.corrwith` Compute pairwise correlation between rows or columns of two DataFrame objects.

Notes

If the Pearson correlation is not well defined return ‘NaN’.

Examples

```
>>> s = pd.Series([0.25, 0.5, 0.2, -0.05])
>>> s.autocorr()
0.10355...
>>> s.autocorr(lag=2)
-0.99999...
```

If the Pearson correlation is not well defined, then ‘NaN’ is returned.

```
>>> s = pd.Series([1, 0, 0, 0])
>>> s.autocorr()
nan
```

pandas.Series.between

`Series.between(self, left, right, inclusive=True)`

Return boolean Series equivalent to `left <= series <= right`.

This function returns a boolean vector containing `True` wherever the corresponding Series element is between the boundary values `left` and `right`. NA values are treated as `False`.

Parameters

`left` [scalar or list-like] Left boundary.

`right` [scalar or list-like] Right boundary.

`inclusive` [bool, default True] Include boundaries.

Returns

`Series` Series representing whether each element is between left and right (inclusive).

See also:

`Series.gt` Greater than of series and other.

`Series.lt` Less than of series and other.

Notes

This function is equivalent to `(left <= ser) & (ser <= right)`

Examples

```
>>> s = pd.Series([2, 0, 4, 8, np.nan])
```

Boundary values are included by default:

```
>>> s.between(1, 4)
0      True
1     False
2      True
3     False
4     False
dtype: bool
```

With *inclusive* set to `False` boundary values are excluded:

```
>>> s.between(1, 4, inclusive=False)
0      True
1     False
2     False
3     False
4     False
dtype: bool
```

left and *right* can be any scalar value:

```
>>> s = pd.Series(['Alice', 'Bob', 'Carol', 'Eve'])
>>> s.between('Anna', 'Daniel')
0     False
1      True
2      True
3     False
dtype: bool
```

pandas.Series.between_time

`Series.between_time(self: ~FrameOrSeries, start_time, end_time, include_start: bool = True, include_end: bool = True, axis=None) → ~FrameOrSeries`
Select values between particular times of the day (e.g., 9:00-9:30 AM).

By setting `start_time` to be later than `end_time`, you can get the times that are *not* between the two times.

Parameters

start_time [datetime.time or str]
end_time [datetime.time or str]
include_start [bool, default True]
include_end [bool, default True]
axis [{0 or ‘index’, 1 or ‘columns’}, default 0] New in version 0.24.0.

Returns

Series or DataFrame

Raises

TypeError If the index is not a [DatetimeIndex](#)

See also:

[**at_time**](#) Select values at a particular time of the day.

[**first**](#) Select initial periods of time series based on a date offset.

[**last**](#) Select final periods of time series based on a date offset.

[**DatetimeIndex.indexer_between_time**](#) Get just the index locations for values between particular times of the day.

Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='1D20min')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
              A
2018-04-09 00:00:00 1
2018-04-10 00:20:00 2
2018-04-11 00:40:00 3
2018-04-12 01:00:00 4
```

```
>>> ts.between_time('0:15', '0:45')
              A
2018-04-10 00:20:00 2
2018-04-11 00:40:00 3
```

You get the times that are *not* between two times by setting `start_time` later than `end_time`:

```
>>> ts.between_time('0:45', '0:15')
              A
2018-04-09 00:00:00 1
2018-04-12 01:00:00 4
```

pandas.Series.bfill

`Series.bfill(self: ~FrameOrSeries, axis=None, inplace: bool = False, limit=None, downcast=None) → Union[~FrameOrSeries, NoneType]`

Synonym for [`DataFrame.fillna\(\)`](#) with `method='bfill'`.

Returns

`%(klass)s or None` Object with missing values filled or None if `inplace=True`.

pandas.Series.bool

`Series.bool (self)`

Return the bool of a single element PandasObject.

This must be a boolean scalar value, either True or False. Raise a ValueError if the PandasObject does not have exactly 1 element, or that element is not boolean

Returns

bool Same single boolean value converted to bool type.

pandas.Series.cat

`Series.cat ()`

Accessor object for categorical properties of the Series values.

Be aware that assigning to *categories* is a inplace operation, while all methods return new categorical data per default (but can be called with *inplace=True*).

Parameters

data [Series or CategoricalIndex]

Examples

```
>>> s.cat.categories
>>> s.cat.categories = list('abc')
>>> s.cat.rename_categories(list('cab'))
>>> s.cat.reorder_categories(list('cab'))
>>> s.cat.add_categories(['d','e'])
>>> s.cat.remove_categories(['d'])
>>> s.cat.remove_unused_categories()
>>> s.cat.set_categories(list('abcde'))
>>> s.cat.as_ordered()
>>> s.cat.as_unordered()
```

pandas.Series.clip

`Series.clip (self: ~FrameOrSeries, lower=None, upper=None, axis=None, inplace: bool = False,`

`*args, **kwargs) → ~FrameOrSeries`

Trim values at input threshold(s).

Assigns values outside boundary to boundary values. Thresholds can be singular values or array like, and in the latter case the clipping is performed element-wise in the specified axis.

Parameters

lower [float or array_like, default None] Minimum threshold value. All values below this threshold will be set to it.

upper [float or array_like, default None] Maximum threshold value. All values above this threshold will be set to it.

axis [int or str axis name, optional] Align object with lower and upper along the given axis.

inplace [bool, default False] Whether to perform the operation in place on the data.

New in version 0.21.0.

***args, **kwargs** Additional keywords have no effect but might be accepted for compatibility with numpy.

Returns

Series or DataFrame Same type as calling object with the values outside the clip boundaries replaced.

Examples

```
>>> data = {'col_0': [9, -3, 0, -1, 5], 'col_1': [-2, -7, 6, 8, -5]}
>>> df = pd.DataFrame(data)
>>> df
   col_0  col_1
0      9     -2
1     -3     -7
2      0      6
3     -1      8
4      5     -5
```

Clips per column using lower and upper thresholds:

```
>>> df.clip(-4, 6)
   col_0  col_1
0      6     -2
1     -3     -4
2      0      6
3     -1      6
4      5     -4
```

Clips using specific lower and upper thresholds per column element:

```
>>> t = pd.Series([2, -4, -1, 6, 3])
>>> t
0    2
1   -4
2   -1
3    6
4    3
dtype: int64
```

```
>>> df.clip(t, t + 4, axis=0)
   col_0  col_1
0      6      2
1     -3     -4
2      0      3
3      6      8
4      5      3
```

pandas.Series.combine

`Series.combine(self, other, func, fill_value=None)`

Combine the Series with a Series or scalar according to *func*.

Combine the Series and *other* using *func* to perform elementwise selection for combined Series. *fill_value* is assumed when value is missing at some index from one of the two objects being combined.

Parameters

other [Series or scalar] The value(s) to be combined with the *Series*.

func [function] Function that takes two scalars as inputs and returns an element.

fill_value [scalar, optional] The value to assume when an index is missing from one Series or the other. The default specifies to use the appropriate NaN value for the underlying dtype of the Series.

Returns

Series The result of combining the Series with the other object.

See also:

`Series.combine_first` Combine Series values, choosing the calling Series' values first.

Examples

Consider 2 Datasets `s1` and `s2` containing highest clocked speeds of different birds.

```
>>> s1 = pd.Series({'falcon': 330.0, 'eagle': 160.0})
>>> s1
falcon    330.0
eagle     160.0
dtype: float64
>>> s2 = pd.Series({'falcon': 345.0, 'eagle': 200.0, 'duck': 30.0})
>>> s2
falcon    345.0
eagle     200.0
duck      30.0
dtype: float64
```

Now, to combine the two datasets and view the highest speeds of the birds across the two datasets

```
>>> s1.combine(s2, max)
duck        NaN
eagle     200.0
falcon    345.0
dtype: float64
```

In the previous example, the resulting value for `duck` is missing, because the maximum of a NaN and a float is a NaN. So, in the example, we set `fill_value=0`, so the maximum value returned will be the value from some dataset.

```
>>> s1.combine(s2, max, fill_value=0)
duck     30.0
eagle    200.0
falcon   345.0
dtype: float64
```

pandas.Series.combine_first

`Series.combine_first(self, other)`

Combine Series values, choosing the calling Series's values first.

Parameters

`other` [Series] The value(s) to be combined with the *Series*.

Returns

`Series` The result of combining the Series with the other object.

See also:

`Series.combine` Perform elementwise operation on two Series using a given function.

Notes

Result index will be the union of the two indexes.

Examples

```
>>> s1 = pd.Series([1, np.nan])
>>> s2 = pd.Series([3, 4])
>>> s1.combine_first(s2)
0    1.0
1    4.0
dtype: float64
```

pandas.Series.convert_dtypes

`Series.convert_dtypes(self: ~FrameOrSeries, infer_objects: bool = True, convert_string: bool = True, convert_integer: bool = True, convert_boolean: bool = True)`
→ `~FrameOrSeries`

Convert columns to best possible dtypes using dtypes supporting `pd.NA`.

New in version 1.0.0.

Parameters

`infer_objects` [bool, default True] Whether object dtypes should be converted to the best possible types.

`convert_string` [bool, default True] Whether object dtypes should be converted to `StringDtype()`.

`convert_integer` [bool, default True] Whether, if possible, conversion can be done to integer extension types.

`convert_boolean` [bool, defaults True] Whether object dtypes should be converted to `BooleanDtypes()`.

Returns

`Series or DataFrame` Copy of input object with new dtype.

See also:

`infer_objects` Infer dtypes of objects.
`to_datetime` Convert argument to datetime.
`to_timedelta` Convert argument to timedelta.
`to_numeric` Convert argument to a numeric type.

Notes

By default, `convert_dtypes` will attempt to convert a Series (or each Series in a DataFrame) to dtypes that support `pd.NA`. By using the options `convert_string`, `convert_integer`, and `convert_boolean`, it is possible to turn off individual conversions to `StringDtype`, the integer extension types or `BooleanDtype`, respectively.

For object-dtyped columns, if `infer_objects` is `True`, use the inference rules as during normal Series/DataFrame construction. Then, if possible, convert to `StringDtype`, `BooleanDtype` or an appropriate integer extension type, otherwise leave as `object`.

If the dtype is integer, convert to an appropriate integer extension type.

If the dtype is numeric, and consists of all integers, convert to an appropriate integer extension type.

In the future, as new dtypes are added that support `pd.NA`, the results of this method will change to support those new dtypes.

Examples

```
>>> df = pd.DataFrame(  
...     {  
...         "a": pd.Series([1, 2, 3], dtype=np.dtype("int32")),  
...         "b": pd.Series(["x", "y", "z"], dtype=np.dtype("O")),  
...         "c": pd.Series([True, False, np.nan], dtype=np.dtype("O")),  
...         "d": pd.Series(["h", "i", np.nan], dtype=np.dtype("O")),  
...         "e": pd.Series([10, np.nan, 20], dtype=np.dtype("float")),  
...         "f": pd.Series([np.nan, 100.5, 200], dtype=np.dtype("float")),  
...     }  
... )
```

Start with a DataFrame with default dtypes.

```
>>> df  
      a   b      c      d      e      f  
0   1   x    True     h  10.0    NaN  
1   2   y   False     i    NaN  100.5  
2   3   z     NaN    NaN  20.0  200.0
```

```
>>> df.dtypes  
a      int32  
b      object  
c      object  
d      object  
e    float64  
f    float64  
dtype: object
```

Convert the DataFrame to use best possible dtypes.

```
>>> dfn = df.convert_dtypes()
>>> dfn
   a    b     c      d      e      f
0  1    x   True    h    10    NaN
1  2    y  False   i  <NA>  100.5
2  3    z   <NA>  <NA>    20  200.0
```

```
>>> dfn.dtypes
a      Int32
b      string
c    boolean
d      string
e      Int64
f    float64
dtype: object
```

Start with a Series of strings and missing data represented by np.nan.

```
>>> s = pd.Series(["a", "b", np.nan])
>>> s
0    a
1    b
2    NaN
dtype: object
```

Obtain a Series with dtype StringDtype.

```
>>> s.convert_dtypes()
0    a
1    b
2    <NA>
dtype: string
```

pandas.Series.copy

`Series.copy(self: ~FrameOrSeries, deep: bool = True) → ~FrameOrSeries`

Make a copy of this object's indices and data.

When `deep=True` (default), a new object will be created with a copy of the calling object's data and indices. Modifications to the data or indices of the copy will not be reflected in the original object (see notes below).

When `deep=False`, a new object will be created without copying the calling object's data or index (only references to the data and index are copied). Any changes to the data of the original will be reflected in the shallow copy (and vice versa).

Parameters

deep [bool, default True] Make a deep copy, including a copy of the data and the indices.
With `deep=False` neither the indices nor the data are copied.

Returns

copy [Series or DataFrame] Object type matches caller.

Notes

When `deep=True`, data is copied but actual Python objects will not be copied recursively, only the reference to the object. This is in contrast to `copy.deepcopy` in the Standard Library, which recursively copies object data (see examples below).

While `Index` objects are copied when `deep=True`, the underlying numpy array is not copied for performance reasons. Since `Index` is immutable, the underlying data can be safely shared and a copy is not needed.

Examples

```
>>> s = pd.Series([1, 2], index=["a", "b"])
>>> s
a    1
b    2
dtype: int64
```

```
>>> s_copy = s.copy()
>>> s_copy
a    1
b    2
dtype: int64
```

Shallow copy versus default (deep) copy:

```
>>> s = pd.Series([1, 2], index=["a", "b"])
>>> deep = s.copy()
>>> shallow = s.copy(deep=False)
```

Shallow copy shares data and index with original.

```
>>> s is shallow
False
>>> s.values is shallow.values and s.index is shallow.index
True
```

Deep copy has own copy of data and index.

```
>>> s is deep
False
>>> s.values is deep.values or s.index is deep.index
False
```

Updates to the data shared by shallow copy and original is reflected in both; deep copy remains unchanged.

```
>>> s[0] = 3
>>> shallow[1] = 4
>>> s
a    3
b    4
dtype: int64
>>> shallow
a    3
b    4
dtype: int64
```

(continues on next page)

(continued from previous page)

```
>>> deep
a    1
b    2
dtype: int64
```

Note that when copying an object containing Python objects, a deep copy will copy the data, but will not do so recursively. Updating a nested data object will be reflected in the deep copy.

```
>>> s = pd.Series([[1, 2], [3, 4]])
>>> deep = s.copy()
>>> s[0][0] = 10
>>> s
0    [10, 2]
1    [3, 4]
dtype: object
>>> deep
0    [10, 2]
1    [3, 4]
dtype: object
```

pandas.Series.corr

`Series.corr(self, other, method='pearson', min_periods=None)`

Compute correlation with `other` Series, excluding missing values.

Parameters

other [Series] Series with which to compute the correlation.

method [{‘pearson’, ‘kendall’, ‘spearman’} or callable] Method used to compute correlation:

- `pearson` : Standard correlation coefficient
- `kendall` : Kendall Tau correlation coefficient
- `spearman` : Spearman rank correlation
- `callable`: Callable with input two 1d ndarrays and returning a float.

New in version 0.24.0: Note that the returned matrix from `corr` will have 1 along the diagonals and will be symmetric regardless of the callable’s behavior.

min_periods [int, optional] Minimum number of observations needed to have a valid result.

Returns

float Correlation with other.

Examples

```
>>> def histogram_intersection(a, b):
...     v = np.minimum(a, b).sum().round(decimals=1)
...     return v
>>> s1 = pd.Series([.2, .0, .6, .2])
>>> s2 = pd.Series([.3, .6, .0, .1])
>>> s1.corr(s2, method=histogram_intersection)
0.3
```

pandas.Series.count

`Series.count(self, level=None)`

Return number of non-NA/null observations in the Series.

Parameters

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a smaller Series.

Returns

int or Series (if level specified) Number of non-null values in the Series.

Examples

```
>>> s = pd.Series([0.0, 1.0, np.nan])
>>> s.count()
2
```

pandas.Series.cov

`Series.cov(self, other, min_periods=None)`

Compute covariance with Series, excluding missing values.

Parameters

other [Series] Series with which to compute the covariance.

min_periods [int, optional] Minimum number of observations needed to have a valid result.

Returns

float Covariance between Series and other normalized by N-1 (unbiased estimator).

Examples

```
>>> s1 = pd.Series([0.90010907, 0.13484424, 0.62036035])
>>> s2 = pd.Series([0.12528585, 0.26962463, 0.51111198])
>>> s1.cov(s2)
-0.01685762652715874
```

pandas.Series.cummax

`Series.cummax(self, axis=None, skipna=True, *args, **kwargs)`

Return cumulative maximum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative maximum.

Parameters

`axis [{0 or ‘index’, 1 or ‘columns’}, default 0]` The index or the name of the axis. 0 is equivalent to None or ‘index’.

`skipna [bool, default True]` Exclude NA/null values. If an entire row/column is NA, the result will be NA.

`*args, **kwargs` : Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

`scalar or Series`

See also:

`core.window.Expanding.max` Similar functionality but ignores NaN values.

`Series.max` Return the maximum over Series axis.

`Series.cummax` Return cumulative maximum over Series axis.

`Series.cummin` Return cumulative minimum over Series axis.

`Series.cumsum` Return cumulative sum over Series axis.

`Series.cumprod` Return cumulative product over Series axis.

Examples

Series

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cummax()
0      2.0
1      NaN
2      5.0
3      5.0
4      5.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cummax(skipna=False)
0      2.0
1      NaN
2      NaN
3      NaN
4      NaN
dtype: float64
```

DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                     [3.0, np.nan],
...                     [1.0, 0.0]],
...                     columns=list('AB'))
>>> df
   A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the maximum in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cummax()
   A    B
0  2.0  1.0
1  3.0  NaN
2  3.0  1.0
```

To iterate over columns and find the maximum in each row, use `axis=1`

```
>>> df.cummax(axis=1)
   A    B
0  2.0  2.0
1  3.0  NaN
2  1.0  1.0
```

pandas.Series.cummin

`Series.cummin(self, axis=None, skipna=True, *args, **kwargs)`

Return cumulative minimum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative minimum.

Parameters

`axis` [{0 or ‘index’, 1 or ‘columns’}, default 0] The index or the name of the axis. 0 is equivalent to None or ‘index’.

`skipna` [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

`*args, **kwargs` : Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

scalar or Series

See also:

`core.window.Expanding.min` Similar functionality but ignores NaN values.

`Series.min` Return the minimum over Series axis.

`Series.cummax` Return cumulative maximum over Series axis.

`Series.cummin` Return cumulative minimum over Series axis.

`Series.cumsum` Return cumulative sum over Series axis.

`Series.cumprod` Return cumulative product over Series axis.

Examples**Series**

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cummin()
0    2.0
1    NaN
2    2.0
3   -1.0
4   -1.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cummin(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                     ...,
...                     [3.0, np.nan],
...                     [1.0, 0.0]],
...                     columns=list('AB'))
>>> df
   A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the minimum in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cummin()
   A    B
0  2.0  1.0
1  2.0  NaN
2  1.0  0.0
```

To iterate over columns and find the minimum in each row, use `axis=1`

```
>>> df.cummin(axis=1)
   A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

pandas.Series.cumprod

`Series.cumprod(self, axis=None, skipna=True, *args, **kwargs)`

Return cumulative product over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative product.

Parameters

`axis` [{0 or ‘index’, 1 or ‘columns’}, default 0] The index or the name of the axis. 0 is equivalent to None or ‘index’.

`skipna` [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

`*args, **kwargs` : Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

scalar or Series

See also:

`core.window.Expanding.prod` Similar functionality but ignores NaN values.

`Series.prod` Return the product over Series axis.

`Series.cummax` Return cumulative maximum over Series axis.

`Series.cummin` Return cumulative minimum over Series axis.

`Series.cumsum` Return cumulative sum over Series axis.

`Series.cumprod` Return cumulative product over Series axis.

Examples**Series**

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cumprod()
0    2.0
1    NaN
2   10.0
3  -10.0
4   -0.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cumprod(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                     [3.0, np.nan],
...                     [1.0, 0.0]],
...                     columns=list('AB'))
>>> df
     A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the product in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cumprod()
      A      B
0   2.0   1.0
1   6.0   NaN
2   6.0   0.0
```

To iterate over columns and find the product in each row, use `axis=1`

```
>>> df.cumprod(axis=1)
      A      B
0   2.0   2.0
1   3.0   NaN
2   1.0   0.0
```

pandas.Series.cumsum

`Series.cumsum(self, axis=None, skipna=True, *args, **kwargs)`

Return cumulative sum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative sum.

Parameters

`axis` [{0 or ‘index’, 1 or ‘columns’}, default 0] The index or the name of the axis. 0 is equivalent to None or ‘index’.

`skipna` [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

`*args, **kwargs` : Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

`scalar or Series`

See also:

`core.window.Expanding.sum` Similar functionality but ignores NaN values.

`Series.sum` Return the sum over Series axis.

`Series.cummax` Return cumulative maximum over Series axis.

`Series.cummin` Return cumulative minimum over Series axis.

`Series.cumsum` Return cumulative sum over Series axis.

`Series.cumprod` Return cumulative product over Series axis.

Examples

Series

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cumsum()
0    2.0
1    NaN
2    7.0
3    6.0
4    6.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cumsum(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                     [3.0, np.nan],
...                     [1.0, 0.0]],
...                     columns=list('AB'))
>>> df
     A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the sum in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cumsum()
     A    B
0  2.0  1.0
1  5.0  NaN
2  6.0  1.0
```

To iterate over columns and find the sum in each row, use `axis=1`

```
>>> df.cumsum(axis=1)
     A    B
```

0	2.0	3.0
1	3.0	NaN
2	1.0	1.0

pandas.Series.describe

`Series.describe(self: ~FrameOrSeries, percentiles=None, include=None, exclude=None) → ~FrameOrSeries`
Generate descriptive statistics.

Descriptive statistics include those that summarize the central tendency, dispersion and shape of a dataset's distribution, excluding NaN values.

Analyzes both numeric and object series, as well as DataFrame column sets of mixed data types. The output will vary depending on what is provided. Refer to the notes below for more detail.

Parameters

percentiles [list-like of numbers, optional] The percentiles to include in the output. All should fall between 0 and 1. The default is [.25, .5, .75], which returns the 25th, 50th, and 75th percentiles.

include ['all', list-like of dtypes or None (default), optional] A white list of data types to include in the result. Ignored for Series. Here are the options:

- 'all' : All columns of the input will be included in the output.
- A list-like of dtypes : Limits the results to the provided data types. To limit the result to numeric types submit `numpy.number`. To limit it instead to object columns submit the `numpy.object` data type. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(include=['O'])`). To select pandas categorical columns, use 'category'
- None (default) : The result will include all numeric columns.

exclude [list-like of dtypes or None (default), optional,] A black list of data types to omit from the result. Ignored for Series. Here are the options:

- A list-like of dtypes : Excludes the provided data types from the result. To exclude numeric types submit `numpy.number`. To exclude object columns submit the data type `numpy.object`. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(exclude=['O'])`). To exclude pandas categorical columns, use 'category'
- None (default) : The result will exclude nothing.

Returns

`Series or DataFrame` Summary statistics of the Series or Dataframe provided.

See also:

`DataFrame.count` Count number of non-NA/null observations.

`DataFrame.max` Maximum of the values in the object.

`DataFrame.min` Minimum of the values in the object.

`DataFrame.mean` Mean of the values.

`DataFrame.std` Standard deviation of the observations.

`DataFrame.select_dtypes` Subset of a DataFrame including/excluding columns based on their dtype.

Notes

For numeric data, the result's index will include `count`, `mean`, `std`, `min`, `max` as well as lower, 50 and upper percentiles. By default the lower percentile is 25 and the upper percentile is 75. The 50 percentile is the same as the median.

For object data (e.g. strings or timestamps), the result's index will include `count`, `unique`, `top`, and `freq`. The `top` is the most common value. The `freq` is the most common value's frequency. Timestamps also include the `first` and `last` items.

If multiple object values have the highest count, then the `count` and `top` results will be arbitrarily chosen from among those with the highest count.

For mixed data types provided via a `DataFrame`, the default is to return only an analysis of numeric columns. If the dataframe consists only of object and categorical data without any numeric columns, the default is to return an analysis of both the object and categorical columns. If `include='all'` is provided as an option, the result will include a union of attributes of each type.

The `include` and `exclude` parameters can be used to limit which columns in a `DataFrame` are analyzed for the output. The parameters are ignored when analyzing a `Series`.

Examples

Describing a numeric Series.

```
>>> s = pd.Series([1, 2, 3])
>>> s.describe()
count    3.0
mean     2.0
std      1.0
min     1.0
25%    1.5
50%    2.0
75%    2.5
max     3.0
dtype: float64
```

Describing a categorical Series.

```
>>> s = pd.Series(['a', 'a', 'b', 'c'])
>>> s.describe()
count    4
unique   3
top      a
freq     2
dtype: object
```

Describing a timestamp Series.

```
>>> s = pd.Series([
...     np.datetime64("2000-01-01"),
...     np.datetime64("2010-01-01"),
...     np.datetime64("2010-01-01")])
```

(continues on next page)

(continued from previous page)

```
... ])
>>> s.describe()
count              3
unique             2
top    2010-01-01 00:00:00
freq               2
first   2000-01-01 00:00:00
last    2010-01-01 00:00:00
dtype: object
```

Describing a DataFrame. By default only numeric fields are returned.

```
>>> df = pd.DataFrame({'categorical': pd.Categorical(['d','e','f']),
...                      'numeric': [1, 2, 3],
...                      'object': ['a', 'b', 'c']}
... )
>>> df.describe()
      numeric
count      3.0
mean       2.0
std        1.0
min        1.0
25%       1.5
50%       2.0
75%       2.5
max       3.0
```

Describing all columns of a DataFrame regardless of data type.

```
>>> df.describe(include='all')
      categorical  numeric  object
count          3      3.0      3
unique         3      NaN      3
top            f      NaN      c
freq           1      NaN      1
mean          NaN      2.0      NaN
std            NaN      1.0      NaN
min            NaN      1.0      NaN
25%           NaN      1.5      NaN
50%           NaN      2.0      NaN
75%           NaN      2.5      NaN
max            NaN      3.0      NaN
```

Describing a column from a DataFrame by accessing it as an attribute.

```
>>> df.numeric.describe()
count      3.0
mean       2.0
std        1.0
min        1.0
25%       1.5
50%       2.0
75%       2.5
max       3.0
Name: numeric, dtype: float64
```

Including only numeric columns in a DataFrame description.

```
>>> df.describe(include=[np.number])
      numeric
count      3.0
mean      2.0
std       1.0
min       1.0
25%      1.5
50%      2.0
75%      2.5
max      3.0
```

Including only string columns in a DataFrame description.

```
>>> df.describe(include=[np.object])
      object
count      3
unique     3
top       c
freq      1
```

Including only categorical columns from a DataFrame description.

```
>>> df.describe(include=['category'])
      categorical
count      3
unique     3
top       f
freq      1
```

Excluding numeric columns from a DataFrame description.

```
>>> df.describe(exclude=[np.number])
      categorical  object
count          3      3
unique         3      3
top            f      c
freq           1      1
```

Excluding object columns from a DataFrame description.

```
>>> df.describe(exclude=[np.object])
      categorical  numeric
count          3      3.0
unique         3      NaN
top            f      NaN
freq           1      NaN
mean           NaN     2.0
std            NaN     1.0
min            NaN     1.0
25%           NaN     1.5
50%           NaN     2.0
75%           NaN     2.5
max            NaN     3.0
```

pandas.Series.diff

`Series.diff(self, periods=1)`

First discrete difference of element.

Calculates the difference of a Series element compared with another element in the Series (default is element in previous row).

Parameters

`periods` [int, default 1] Periods to shift for calculating difference, accepts negative values.

Returns

`Series` First differences of the Series.

See also:

`Series.pct_change` Percent change over given number of periods.

`Series.shift` Shift index by desired number of periods with an optional time freq.

`DataFrame.diff` First discrete difference of object.

Notes

For boolean dtypes, this uses `operator.xor()` rather than `operator.sub()`.

Examples

Difference with previous row

```
>>> s = pd.Series([1, 1, 2, 3, 5, 8])
>>> s.diff()
0      NaN
1      0.0
2      1.0
3      1.0
4      2.0
5      3.0
dtype: float64
```

Difference with 3rd previous row

```
>>> s.diff(periods=3)
0      NaN
1      NaN
2      NaN
3      2.0
4      4.0
5      6.0
dtype: float64
```

Difference with following row

```
>>> s.diff(periods=-1)
0      0.0
1     -1.0
2     -1.0
3     -2.0
4     -3.0
5      NaN
dtype: float64
```

pandas.Series.div

`Series.div(self, other, level=None, fill_value=None, axis=0)`

Return Floating division of series and other, element-wise (binary operator *truediv*).

Equivalent to `series / other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

`Series.rtruediv`

Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.divide(b, fill_value=0)
a    1.0
b    inf
c    inf
```

(continues on next page)

(continued from previous page)

```
d    0.0
e    NaN
dtype: float64
```

pandas.Series.divide

`Series.divide(self, other, level=None, fill_value=None, axis=0)`

Return Floating division of series and other, element-wise (binary operator *truediv*).

Equivalent to `series / other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

`other` [Series or scalar value]

`fill_value` [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

`level` [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

`Series` The result of the operation.

See also:

`Series.rtruediv`

Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.divide(b, fill_value=0)
a    1.0
b    inf
c    inf
d    0.0
e    NaN
dtype: float64
```

pandas.Series.divmod

`Series.divmod(self, other, level=None, fill_value=None, axis=0)`

Return Integer division and modulo of series and other, element-wise (binary operator *divmod*).

Equivalent to `series divmod other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

`Series.rdivmod`

pandas.Series.dot

`Series.dot(self, other)`

Compute the dot product between the Series and the columns of other.

This method computes the dot product between the Series and another one, or the Series and each columns of a DataFrame, or the Series and each columns of an array.

It can also be called using `self @ other` in Python >= 3.5.

Parameters

other [Series, DataFrame or array-like] The other object to compute the dot product with its columns.

Returns

scalar, Series or numpy.ndarray Return the dot product of the Series and other if other is a Series, the Series of the dot product of Series and each rows of other if other is a DataFrame or a numpy.ndarray between the Series and each columns of the numpy array.

See also:

`DataFrame.dot` Compute the matrix product with the DataFrame.

`Series.mul` Multiplication of series and other, element-wise.

Notes

The Series and other has to share the same index if other is a Series or a DataFrame.

Examples

```
>>> s = pd.Series([0, 1, 2, 3])
>>> other = pd.Series([-1, 2, -3, 4])
>>> s.dot(other)
8
>>> s @ other
8
>>> df = pd.DataFrame([[0, 1], [-2, 3], [4, -5], [6, 7]])
>>> s.dot(df)
0    24
1    14
dtype: int64
>>> arr = np.array([[0, 1], [-2, 3], [4, -5], [6, 7]])
>>> s.dot(arr)
array([24, 14])
```

`pandas.Series.drop`

`Series.drop(self, labels=None, axis=0, index=None, columns=None, level=None, inplace=False, errors='raise')`

Return Series with specified index labels removed.

Remove elements of a Series based on specifying the index labels. When using a multi-index, labels on different levels can be removed by specifying the level.

Parameters

labels [single label or list-like] Index labels to drop.

axis [0, default 0] Redundant for application on Series.

index [single label or list-like] Redundant for application on Series, but ‘index’ can be used instead of ‘labels’.

New in version 0.21.0.

columns [single label or list-like] No change is made to the Series; use ‘index’ or ‘labels’ instead.

New in version 0.21.0.

level [int or level name, optional] For MultiIndex, level for which the labels will be removed.

inplace [bool, default False] If True, do operation inplace and return None.

errors [{‘ignore’, ‘raise’}, default ‘raise’] If ‘ignore’, suppress error and only existing labels are dropped.

Returns

Series Series with specified index labels removed.

Raises

KeyError If none of the labels are found in the index.

See also:

`Series.reindex` Return only specified index labels of Series.

`Series.dropna` Return series without null values.

`Series.drop_duplicates` Return Series with duplicate values removed.

`DataFrame.drop` Drop specified labels from rows or columns.

Examples

```
>>> s = pd.Series(data=np.arange(3), index=['A', 'B', 'C'])
>>> s
A    0
B    1
C    2
dtype: int64
```

Drop labels B en C

```
>>> s.drop(labels=['B', 'C'])
A    0
dtype: int64
```

Drop 2nd level label in MultiIndex Series

```
>>> midx = pd.MultiIndex(levels=[['lama', 'cow', 'falcon'],
...                           ['speed', 'weight', 'length']],
...                           codes=[[0, 0, 0, 1, 1, 1, 2, 2, 2],
...                                  [0, 1, 2, 0, 1, 2, 0, 1, 2]])
>>> s = pd.Series([45, 200, 1.2, 30, 250, 1.5, 320, 1, 0.3],
...                 index=midx)
>>> s
lama    speed      45.0
        weight     200.0
        length     1.2
cow     speed      30.0
        weight     250.0
        length     1.5
falcon   speed     320.0
        weight      1.0
        length     0.3
dtype: float64
```

```
>>> s.drop(labels='weight', level=1)
lama    speed      45.0
        length     1.2
cow     speed      30.0
        length     1.5
falcon   speed     320.0
        length     0.3
dtype: float64
```

`pandas.Series.drop_duplicates`

`Series.drop_duplicates(self, keep='first', inplace=False)`

Return Series with duplicate values removed.

Parameters

`keep` [{‘first’, ‘last’, False}, default ‘first’] Method to handle dropping duplicates:

- ‘first’ : Drop duplicates except for the first occurrence.
- ‘last’ : Drop duplicates except for the last occurrence.
- False : Drop all duplicates.

`inplace` [bool, default False] If True, performs operation inplace and returns None.

Returns

`Series` Series with duplicates dropped.

See also:

`Index.drop_duplicates` Equivalent method on Index.

`DataFrame.drop_duplicates` Equivalent method on DataFrame.

`Series.duplicated` Related method on Series, indicating duplicate Series values.

Examples

Generate a Series with duplicated entries.

```
>>> s = pd.Series(['lama', 'cow', 'lama', 'beetle', 'lama', 'hippo'],
...                  name='animal')
>>> s
0      lama
1      cow
2      lama
3    beetle
4      lama
5      hippo
Name: animal, dtype: object
```

With the ‘keep’ parameter, the selection behaviour of duplicated values can be changed. The value ‘first’ keeps the first occurrence for each set of duplicated entries. The default value of keep is ‘first’.

```
>>> s.drop_duplicates()
0      lama
1      cow
3    beetle
5      hippo
Name: animal, dtype: object
```

The value ‘last’ for parameter ‘keep’ keeps the last occurrence for each set of duplicated entries.

```
>>> s.drop_duplicates(keep='last')
1      cow
3    beetle
4      lama
```

(continues on next page)

(continued from previous page)

```
5      hippo
Name: animal, dtype: object
```

The value `False` for parameter ‘keep’ discards all sets of duplicated entries. Setting the value of ‘inplace’ to `True` performs the operation inplace and returns `None`.

```
>>> s.drop_duplicates(keep=False, inplace=True)
>>> s
1      cow
3    beetle
5    hippo
Name: animal, dtype: object
```

pandas.Series.droplevel

`Series.droplevel(self: ~FrameOrSeries, level, axis=0) → ~FrameOrSeries`
Return DataFrame with requested index / column level(s) removed.

New in version 0.24.0.

Parameters

`level` [int, str, or list-like] If a string is given, must be the name of a level If list-like, elements must be names or positional indexes of levels.

`axis` [{0 or ‘index’, 1 or ‘columns’}, default 0]

Returns

`DataFrame` DataFrame with requested index / column level(s) removed.

Examples

```
>>> df = pd.DataFrame([
...     [1, 2, 3, 4],
...     [5, 6, 7, 8],
...     [9, 10, 11, 12]
... ]).set_index([0, 1]).rename_axis(['a', 'b'])
```

```
>>> df.columns = pd.MultiIndex.from_tuples([
...     ('c', 'e'), ('d', 'f')
... ], names=['level_1', 'level_2'])
```

```
>>> df
level_1    c    d
level_2    e    f
a b
1 2        3    4
5 6        7    8
9 10       11   12
```

```
>>> df.droplevel('a')
level_1    c    d
level_2    e    f
```

(continues on next page)

(continued from previous page)

```
b  
2      3  4  
6      7  8  
10     11 12
```

```
>>> df.droplevel('level2', axis=1)  
level_1  c  d  
a b  
1 2      3  4  
5 6      7  8  
9 10     11 12
```

pandas.Series.dropna

`Series.dropna(self, axis=0, inplace=False, how=None)`

Return a new Series with missing values removed.

See the [User Guide](#) for more on which values are considered missing, and how to work with missing data.

Parameters

`axis` [{0 or ‘index’}, default 0] There is only one axis to drop values from.

`inplace` [bool, default False] If True, do operation inplace and return None.

`how` [str, optional] Not in use. Kept for compatibility.

Returns

`Series` Series with NA entries dropped from it.

See also:

`Series.isna` Indicate missing values.

`Series.notna` Indicate existing (non-missing) values.

`Series.fillna` Replace missing values.

`DataFrame.dropna` Drop rows or columns which contain NA values.

`Index.dropna` Drop missing indices.

Examples

```
>>> ser = pd.Series([1., 2., np.nan])  
>>> ser  
0    1.0  
1    2.0  
2    NaN  
dtype: float64
```

Drop NA values from a Series.

```
>>> ser.dropna()
0    1.0
1    2.0
dtype: float64
```

Keep the Series with valid entries in the same variable.

```
>>> ser.dropna(inplace=True)
>>> ser
0    1.0
1    2.0
dtype: float64
```

Empty strings are not considered NA values. None is considered an NA value.

```
>>> ser = pd.Series([np.NaN, 2, pd.NaT, '', None, 'I stay'])
>>> ser
0      NaN
1        2
2      NaT
3
4      None
5    I stay
dtype: object
>>> ser.dropna()
1        2
3
5    I stay
dtype: object
```

pandas.Series.dt

`Series.dt()`

Accessor object for datetimelike properties of the Series values.

Examples

```
>>> s.dt.hour
>>> s.dt.second
>>> s.dt.quarter
```

Returns a Series indexed like the original Series. Raises TypeError if the Series does not contain datetimelike values.

pandas.Series.duplicated

`Series.duplicated(self, keep='first')`

Indicate duplicate Series values.

Duplicated values are indicated as `True` values in the resulting Series. Either all duplicates, all except the first or all except the last occurrence of duplicates can be indicated.

Parameters

`keep` [{‘first’, ‘last’, False}, default ‘first’] Method to handle dropping duplicates:

- ‘first’ : Mark duplicates as `True` except for the first occurrence.
- ‘last’ : Mark duplicates as `True` except for the last occurrence.
- `False` : Mark all duplicates as `True`.

Returns

`Series` Series indicating whether each value has occurred in the preceding values.

See also:

[`Index.duplicated`](#) Equivalent method on pandas.Index.

[`DataFrame.duplicated`](#) Equivalent method on pandas.DataFrame.

[`Series.drop_duplicates`](#) Remove duplicate values from Series.

Examples

By default, for each set of duplicated values, the first occurrence is set on `False` and all others on `True`:

```
>>> animals = pd.Series(['lama', 'cow', 'lama', 'beetle', 'lama'])
>>> animals.duplicated()
0    False
1    False
2     True
3    False
4     True
dtype: bool
```

which is equivalent to

```
>>> animals.duplicated(keep='first')
0    False
1    False
2     True
3    False
4     True
dtype: bool
```

By using ‘last’, the last occurrence of each set of duplicated values is set on `False` and all others on `True`:

```
>>> animals.duplicated(keep='last')
0     True
1    False
2     True
3    False
```

(continues on next page)

(continued from previous page)

```
4    False
dtype: bool
```

By setting `keep` on `False`, all duplicates are `True`:

```
>>> animals.duplicated(keep=False)
0    True
1   False
2    True
3   False
4    True
dtype: bool
```

pandas.Series.eq

`Series.eq(self, other, level=None, fill_value=None, axis=0)`

Return Equal to of series and other, element-wise (binary operator `eq`).

Equivalent to `series == other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

`Series.None`

pandas.Series.equals

`Series.equals(self, other)`

Test whether two objects contain the same elements.

This function allows two Series or DataFrames to be compared against each other to see if they have the same shape and elements. NaNs in the same location are considered equal. The column headers do not need to have the same type, but the elements within the columns must be the same dtype.

Parameters

other [Series or DataFrame] The other Series or DataFrame to be compared with the first.

Returns

bool True if all elements are the same in both objects, False otherwise.

See also:

`Series.eq` Compare two Series objects of the same length and return a Series where each element is True if the element in each Series is equal, False otherwise.

`DataFrame.eq` Compare two DataFrame objects of the same shape and return a DataFrame where each element is True if the respective element in each DataFrame is equal, False otherwise.

`testing.assert_series_equal` Raises an AssertionError if left and right are not equal. Provides an easy interface to ignore inequality in dtypes, indexes and precision among others.

`testing.assert_frame_equal` Like assert_series_equal, but targets DataFrames.

`numpy.array_equal` Return True if two arrays have the same shape and elements, False otherwise.

Notes

This function requires that the elements have the same dtype as their respective elements in the other Series or DataFrame. However, the column labels do not need to have the same type, as long as they are still considered equal.

Examples

```
>>> df = pd.DataFrame({1: [10], 2: [20]})  
>>> df  
   1    2  
0  10  20
```

DataFrames df and exactly_equal have the same types and values for their elements and column labels, which will return True.

```
>>> exactly_equal = pd.DataFrame({1: [10], 2: [20]})  
>>> exactly_equal  
   1    2  
0  10  20  
>>> df.equals(exactly_equal)  
True
```

DataFrames df and different_column_type have the same element types and values, but have different types for the column labels, which will still return True.

```
>>> different_column_type = pd.DataFrame({1.0: [10], 2.0: [20]})  
>>> different_column_type  
   1.0  2.0  
0     10    20  
>>> df.equals(different_column_type)  
True
```

DataFrames df and different_data_type have different types for the same values for their elements, and will return False even though their column labels are the same values and types.

```
>>> different_data_type = pd.DataFrame({1: [10.0], 2: [20.0]})  
>>> different_data_type  
   1    2  
0  10.0  20.0  
>>> df.equals(different_data_type)  
False
```

pandas.Series.ewm

`Series.ewm(self, com=None, span=None, halflife=None, alpha=None, min_periods=0, adjust=True, ignore_na=False, axis=0)`

Provide exponential weighted functions.

Parameters

com [float, optional] Specify decay in terms of center of mass, $\alpha = 1/(1+com)$, for $com \geq 0$.

span [float, optional] Specify decay in terms of span, $\alpha = 2/(span + 1)$, for $span \geq 1$.

halflife [float, optional] Specify decay in terms of half-life, $\alpha = 1 - exp(log(0.5)/halflife)$, for $halflife > 0$.

alpha [float, optional] Specify smoothing factor α directly, $0 < \alpha \leq 1$.

min_periods [int, default 0] Minimum number of observations in window required to have a value (otherwise result is NA).

adjust [bool, default True] Divide by decaying adjustment factor in beginning periods to account for imbalance in relative weightings (viewing EWMA as a moving average).

ignore_na [bool, default False] Ignore missing values when calculating weights; specify True to reproduce pre-0.15.0 behavior.

axis [{0 or ‘index’, 1 or ‘columns’}, default 0] The axis to use. The value 0 identifies the rows, and 1 identifies the columns.

Returns

DataFrame A Window sub-classed for the particular operation.

See also:

[**rolling**](#) Provides rolling window calculations.

[**expanding**](#) Provides expanding transformations.

Notes

Exactly one of center of mass, span, half-life, and alpha must be provided. Allowed values and relationship between the parameters are specified in the parameter descriptions above; see the link at the end of this section for a detailed explanation.

When `adjust` is `True` (default), weighted averages are calculated using weights $(1-\alpha)^{n-1}$, $(1-\alpha)^{n-2}$, ..., $1-\alpha$, 1.

When `adjust` is `False`, weighted averages are calculated recursively as: `weighted_average[0] = arg[0]`; `weighted_average[i] = (1-alpha)*weighted_average[i-1] + alpha*arg[i]`.

When `ignore_na` is `False` (default), weights are based on absolute positions. For example, the weights of `x` and `y` used in calculating the final weighted average of [`x`, `None`, `y`] are $(1-\alpha)^2$ and 1 (if `adjust` is `True`), and $(1-\alpha)^2$ and `alpha` (if `adjust` is `False`).

When `ignore_na` is `True` (reproducing pre-0.15.0 behavior), weights are based on relative positions. For example, the weights of `x` and `y` used in calculating the final weighted average of [`x`, `None`, `y`] are `1-alpha` and 1 (if `adjust` is `True`), and `1-alpha` and `alpha` (if `adjust` is `False`).

More details can be found at https://pandas.pydata.org/pandas-docs/stable/user_guide/computation.html#exponentially-weighted-windows

Examples

```
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})  
>>> df  
      B  
0   0.0  
1   1.0  
2   2.0  
3   NaN  
4   4.0
```

```
>>> df.ewm(com=0.5).mean()  
      B  
0   0.000000  
1   0.750000  
2   1.615385  
3   1.615385  
4   3.670213
```

pandas.Series.expanding

`Series.expanding(self, min_periods=1, center=False, axis=0)`

Provide expanding transformations.

Parameters

min_periods [int, default 1] Minimum number of observations in window required to have a value (otherwise result is NA).

center [bool, default False] Set the labels at the center of the window.

axis [int or str, default 0]

Returns

a Window sub-classed for the particular operation

See also:

[`rolling`](#) Provides rolling window calculations.

[`ewm`](#) Provides exponential weighted functions.

Notes

By default, the result is set to the right edge of the window. This can be changed to the center of the window by setting `center=True`.

Examples

```
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})  
      B  
0    0.0  
1    1.0  
2    2.0  
3    NaN  
4    4.0
```

```
>>> df.expanding(2).sum()  
      B  
0    NaN  
1    1.0  
2    3.0  
3    3.0  
4    7.0
```

pandas.Series.explode

`Series.explode(self) → 'Series'`

Transform each element of a list-like to a row, replicating the index values.

New in version 0.25.0.

Returns

`Series` Exploded lists to rows; index will be duplicated for these rows.

See also:

`Series.str.split` Split string values on specified separator.

`Series.unstack` Unstack, a.k.a. pivot, Series with MultiIndex to produce DataFrame.

`DataFrame.melt` Unpivot a DataFrame from wide format to long format.

`DataFrame.explode` Explode a DataFrame from list-like columns to long format.

Notes

This routine will explode list-likes including lists, tuples, Series, and np.ndarray. The result dtype of the subset rows will be object. Scalars will be returned unchanged. Empty list-likes will result in a np.nan for that row.

Examples

```
>>> s = pd.Series([[1, 2, 3], 'foo', [], [3, 4]])  
>>> s  
0    [1, 2, 3]  
1    foo  
2    []  
3    [3, 4]  
dtype: object
```

```
>>> s.explode()
0      1
0      2
0      3
1    foo
2    NaN
3      3
3      4
dtype: object
```

pandas.Series.factorize

`Series.factorize(self, sort=False, na_sentinel=-1)`

Encode the object as an enumerated type or categorical variable.

This method is useful for obtaining a numeric representation of an array when all that matters is identifying distinct values. `factorize` is available as both a top-level function `pandas.factorize()`, and as a method `Series.factorize()` and `Index.factorize()`.

Parameters

`sort` [bool, default False] Sort `uniques` and shuffle `codes` to maintain the relationship.

`na_sentinel` [int, default -1] Value to mark “not found”.

Returns

`codes` [ndarray] An integer ndarray that's an indexer into `uniques`. `uniques.take(codes)` will have the same values as `values`.

`uniques` [ndarray, Index, or Categorical] The unique valid values. When `values` is Categorical, `uniques` is a Categorical. When `values` is some other pandas object, an `Index` is returned. Otherwise, a 1-D ndarray is returned.

Note: Even if there's a missing value in `values`, `uniques` will *not* contain an entry for it.

See also:

`cut` Discretize continuous-valued array.

`unique` Find the unique value in an array.

Examples

These examples all show `factorize` as a top-level method like `pd.factorize(values)`. The results are identical for methods like `Series.factorize()`.

```
>>> codes, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'])
>>> codes
array([0, 0, 1, 2, 0])
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

With `sort=True`, the `uniques` will be sorted, and `codes` will be shuffled so that the relationship is the maintained.

```
>>> codes, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'], sort=True)
>>> codes
array([1, 1, 0, 2, 1])
>>> uniques
array(['a', 'b', 'c'], dtype=object)
```

Missing values are indicated in `codes` with `na_sentinel` (-1 by default). Note that missing values are never included in `uniques`.

```
>>> codes, uniques = pd.factorize(['b', None, 'a', 'c', 'b'])
>>> codes
array([-1, -1, 1, 2, 0])
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

Thus far, we've only factorized lists (which are internally coerced to NumPy arrays). When factorizing pandas objects, the type of `uniques` will differ. For Categoricals, a `Categorical` is returned.

```
>>> cat = pd.Categorical(['a', 'a', 'c'], categories=['a', 'b', 'c'])
>>> codes, uniques = pd.factorize(cat)
>>> codes
array([0, 0, 1])
>>> uniques
[a, c]
Categories (3, object): [a, b, c]
```

Notice that 'b' is in `uniques.categories`, despite not being present in `cat.values`.

For all other pandas objects, an Index of the appropriate type is returned.

```
>>> cat = pd.Series(['a', 'a', 'c'])
>>> codes, uniques = pd.factorize(cat)
>>> codes
array([0, 0, 1])
>>> uniques
Index(['a', 'c'], dtype='object')
```

pandas.Series.ffill

`Series.ffill(self: ~FrameOrSeries, axis=None, inplace: bool = False, limit=None, downcast=None) → Union[~FrameOrSeries, NoneType]`
 Synonym for `DataFrame.fillna()` with `method='ffill'`.

Returns

`%(klass)s or None` Object with missing values filled or None if `inplace=True`.

pandas.Series.fillna

`Series.fillna(self, value=None, method=None, axis=None, inplace=False, limit=None, downcast=None) → Union[ForwardRef('Series'), NoneType]`
Fill NA/NaN values using the specified method.

Parameters

value [scalar, dict, Series, or DataFrame] Value to use to fill holes (e.g. 0), alternately a dict/Series/DataFrame of values specifying which value to use for each index (for a Series) or column (for a DataFrame). Values not in the dict/Series/DataFrame will not be filled. This value cannot be a list.

method [{‘backfill’, ‘bfill’, ‘pad’, ‘ffill’, None}, default None] Method to use for filling holes in reindexed Series pad / ffill: propagate last valid observation forward to next valid backfill / bfill: use next valid observation to fill gap.

axis [{0 or ‘index’}] Axis along which to fill missing values.

inplace [bool, default False] If True, fill in-place. Note: this will modify any other views on this object (e.g., a no-copy slice for a column in a DataFrame).

limit [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

downcast [dict, default is None] A dict of item->dtype of what to downcast if possible, or the string ‘infer’ which will try to downcast to an appropriate equal type (e.g. float64 to int64 if possible).

Returns

Series or None Object with missing values filled or None if `inplace=True`.

See also:

`interpolate` Fill NaN values using interpolation.

`reindex` Conform object to new index.

`asfreq` Convert TimeSeries to specified frequency.

Examples

```
>>> df = pd.DataFrame([[np.nan, 2, np.nan, 0],
...                     [3, 4, np.nan, 1],
...                     [np.nan, np.nan, np.nan, 5],
...                     [np.nan, 3, np.nan, 4]],
...                     columns=list('ABCD'))
>>> df
   A    B    C    D
0  NaN  2.0  NaN  0
1  3.0  4.0  NaN  1
2  NaN  NaN  NaN  5
3  NaN  3.0  NaN  4
```

Replace all NaN elements with 0s.

```
>>> df.fillna(0)
      A    B    C    D
0   0.0  2.0  0.0  0
1   3.0  4.0  0.0  1
2   0.0  0.0  0.0  5
3   0.0  3.0  0.0  4
```

We can also propagate non-null values forward or backward.

```
>>> df.fillna(method='ffill')
      A    B    C    D
0   NaN  2.0  NaN  0
1   3.0  4.0  NaN  1
2   3.0  4.0  NaN  5
3   3.0  3.0  NaN  4
```

Replace all NaN elements in column ‘A’, ‘B’, ‘C’, and ‘D’, with 0, 1, 2, and 3 respectively.

```
>>> values = {'A': 0, 'B': 1, 'C': 2, 'D': 3}
>>> df.fillna(value=values)
      A    B    C    D
0   0.0  2.0  2.0  0
1   3.0  4.0  2.0  1
2   0.0  1.0  2.0  5
3   0.0  3.0  2.0  4
```

Only replace the first NaN element.

```
>>> df.fillna(value=values, limit=1)
      A    B    C    D
0   0.0  2.0  2.0  0
1   3.0  4.0  NaN  1
2   NaN  1.0  NaN  5
3   NaN  3.0  NaN  4
```

pandas.Series.filter

`Series.filter(self: ~FrameOrSeries, items=None, like: Union[str, NoneType] = None, regex: Union[str, NoneType] = None, axis=None) → ~FrameOrSeries`
Subset the dataframe rows or columns according to the specified index labels.

Note that this routine does not filter a dataframe on its contents. The filter is applied to the labels of the index.

Parameters

`items` [list-like] Keep labels from axis which are in items.

`like` [str] Keep labels from axis for which “like in label == True”.

`regex` [str (regular expression)] Keep labels from axis for which `re.search(regex, label) == True`.

`axis` [{0 or ‘index’, 1 or ‘columns’, None}, default None] The axis to filter on, expressed either as an index (int) or axis name (str). By default this is the info axis, ‘index’ for Series, ‘columns’ for DataFrame.

Returns

same type as input object

See also:

`DataFrame.loc`

Notes

The `items`, `like`, and `regex` parameters are enforced to be mutually exclusive.
`axis` defaults to the info axis that is used when indexing with `[]`.

Examples

```
>>> df = pd.DataFrame(np.array(([1, 2, 3], [4, 5, 6])),  
...                      index=['mouse', 'rabbit'],  
...                      columns=['one', 'two', 'three'])
```

```
>>> # select columns by name  
>>> df.filter(items=['one', 'three'])  
      one   three  
mouse     1       3  
rabbit    4       6
```

```
>>> # select columns by regular expression  
>>> df.filter(regex='e$', axis=1)  
      one   three  
mouse     1       3  
rabbit    4       6
```

```
>>> # select rows containing 'bbi'  
>>> df.filter(like='bbi', axis=0)  
      one   two   three  
rabbit    4     5     6
```

pandas.Series.first

`Series.first(self: ~FrameOrSeries, offset) → ~FrameOrSeries`

Method to subset initial periods of time series data based on a date offset.

Parameters

`offset` [str, DateOffset, dateutil.relativedelta]

Returns

`subset` [same type as caller]

Raises

`TypeError` If the index is not a `DatetimeIndex`

See also:

`last` Select final periods of time series based on a date offset.

at_time Select values at a particular time of the day.

between_time Select values between particular times of the day.

Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1,2,3,4]}, index=i)
>>> ts
          A
2018-04-09  1
2018-04-11  2
2018-04-13  3
2018-04-15  4
```

Get the rows for the first 3 days:

```
>>> ts.first('3D')
          A
2018-04-09  1
2018-04-11  2
```

Notice the data for 3 first calendar days were returned, not the first 3 days observed in the dataset, and therefore data for 2018-04-13 was not returned.

pandas.Series.first_valid_index

`Series.first_valid_index(self)`

Return index for first non-NA/null value.

Returns

scalar [type of index]

Notes

If all elements are non-NA/null, returns None. Also returns None for empty Series/DataFrame.

pandas.Series.floordiv

`Series.floordiv(self, other, level=None, fill_value=None, axis=0)`

Return Integer division of series and other, element-wise (binary operator *floordiv*).

Equivalent to `series // other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

`Series.rfloordiv`

Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.floordiv(b, fill_value=0)
a    1.0
b    NaN
c    NaN
d    0.0
e    NaN
dtype: float64
```

`pandas.Series.ge`

`Series.ge (self, other, level=None, fill_value=None, axis=0)`

Return Greater than or equal to of series and other, element-wise (binary operator *ge*).

Equivalent to `series >= other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

`Series.None`

pandas.Series.get

`Series.get(self, key, default=None)`

Get item from object for given key (ex: DataFrame column).

Returns default value if not found.

Parameters

key [object]

Returns

value [same type as items contained in object]

pandas.Series.groupby

`Series.groupby(self, by=None, axis=0, level=None, as_index: bool = True, sort: bool = True, group_keys: bool = True, squeeze: bool = False, observed: bool = False) → 'groupby_generic.SeriesGroupBy'`

Group Series using a mapper or by a Series of columns.

A groupby operation involves some combination of splitting the object, applying a function, and combining the results. This can be used to group large amounts of data and compute operations on these groups.

Parameters

by [mapping, function, label, or list of labels] Used to determine the groups for the groupby.

If `by` is a function, it's called on each value of the object's index. If a dict or Series is passed, the Series or dict VALUES will be used to determine the groups (the Series' values are first aligned; see `.align()` method). If an ndarray is passed, the values are used as-is determine the groups. A label or list of labels may be passed to group by the columns in `self`. Notice that a tuple is interpreted as a (single) key.

axis [{0 or ‘index’, 1 or ‘columns’}, default 0] Split along rows (0) or columns (1).

level [int, level name, or sequence of such, default None] If the axis is a MultiIndex (hierarchical), group by a particular level or levels.

as_index [bool, default True] For aggregated output, return object with group labels as the index. Only relevant for DataFrame input. `as_index=False` is effectively “SQL-style” grouped output.

sort [bool, default True] Sort group keys. Get better performance by turning this off. Note this does not influence the order of observations within each group. Groupby preserves the order of rows within each group.

group_keys [bool, default True] When calling apply, add group keys to index to identify pieces.

squeeze [bool, default False] Reduce the dimensionality of the return type if possible, otherwise return a consistent type.

observed [bool, default False] This only applies if any of the groupers are Categoricals. If True: only show observed values for categorical groupers. If False: show all values for categorical groupers.

New in version 0.23.0.

Returns

SeriesGroupBy Returns a groupby object that contains information about the groups.

See also:

`resample` Convenience method for frequency conversion and resampling of time series.

Notes

See the [user guide](#) for more.

Examples

```
>>> ser = pd.Series([390., 350., 30., 20.],  
...                   index=['Falcon', 'Falcon', 'Parrot', 'Parrot'], name="Max Speed")  
>>> ser  
Falcon    390.0  
Falcon    350.0  
Parrot     30.0  
Parrot     20.0  
Name: Max Speed, dtype: float64  
>>> ser.groupby(["a", "b", "a", "b"]).mean()  
a      210.0  
b      185.0  
Name: Max Speed, dtype: float64  
>>> ser.groupby(level=0).mean()  
Falcon    370.0  
Parrot     25.0  
Name: Max Speed, dtype: float64  
>>> ser.groupby(ser > 100).mean()  
Max Speed  
False     25.0  
True      370.0  
Name: Max Speed, dtype: float64
```

Grouping by Indexes

We can groupby different levels of a hierarchical index using the *level* parameter:

```
>>> arrays = [['Falcon', 'Falcon', 'Parrot', 'Parrot'],  
...             ['Captive', 'Wild', 'Captive', 'Wild']]  
>>> index = pd.MultiIndex.from_arrays(arrays, names=('Animal', 'Type'))  
>>> ser = pd.Series([390., 350., 30., 20.], index=index, name="Max Speed")  
>>> ser  
Animal  Type  
Falcon  Captive    390.0  
        Wild       350.0  
Parrot  Captive    30.0  
        Wild       20.0  
Name: Max Speed, dtype: float64  
>>> ser.groupby(level=0).mean()  
Animal  
Falcon    370.0  
Parrot     25.0  
Name: Max Speed, dtype: float64  
>>> ser.groupby(level="Type").mean()  
Type  
Captive   210.0
```

(continues on next page)

(continued from previous page)

Wild	185.0
Name:	Max Speed, dtype: float64

pandas.Series.gt

`Series.gt(self, other, level=None, fill_value=None, axis=0)`

Return Greater than of series and other, element-wise (binary operator *gt*).

Equivalent to `series > other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

`Series.None`

pandas.Series.head

`Series.head(self: ~FrameOrSeries, n: int = 5) → ~FrameOrSeries`

Return the first *n* rows.

This function returns the first *n* rows for the object based on position. It is useful for quickly testing if your object has the right type of data in it.

For negative values of *n*, this function returns all rows except the last *n* rows, equivalent to `df[: -n]`.

Parameters

n [int, default 5] Number of rows to select.

Returns

same type as caller The first *n* rows of the caller object.

See also:

`DataFrame.tail` Returns the last *n* rows.

Examples

```
>>> df = pd.DataFrame({'animal': ['alligator', 'bee', 'falcon', 'lion',
...                               'monkey', 'parrot', 'shark', 'whale', 'zebra']})
>>> df
      animal
0  alligator
1        bee
2     falcon
3       lion
4     monkey
5    parrot
6     shark
7     whale
8     zebra
```

Viewing the first 5 lines

```
>>> df.head()
      animal
0  alligator
1        bee
2     falcon
3       lion
4     monkey
```

Viewing the first n lines (three in this case)

```
>>> df.head(3)
      animal
0  alligator
1        bee
2     falcon
```

For negative values of n

```
>>> df.head(-3)
      animal
0  alligator
1        bee
2     falcon
3       lion
4     monkey
5    parrot
```

pandas.Series.hist

`Series.hist(self, by=None, ax=None, grid=True, xlabelsize=None, xrot=None, ylabelsize=None, yrot=None, figsize=None, bins=10, backend=None, **kwargs)`
Draw histogram of the input series using matplotlib.

Parameters

`by` [object, optional] If passed, then used to form histograms for separate groups.

`ax` [matplotlib axis object] If not passed, uses `gca()`.

`grid` [bool, default True] Whether to show axis grid lines.

xlabelsize [int, default None] If specified changes the x-axis label size.

xrot [float, default None] Rotation of x axis labels.

ylabelsize [int, default None] If specified changes the y-axis label size.

yrot [float, default None] Rotation of y axis labels.

figsize [tuple, default None] Figure size in inches by default.

bins [int or sequence, default 10] Number of histogram bins to be used. If an integer is given, bins + 1 bin edges are calculated and returned. If bins is a sequence, gives bin edges, including left edge of first bin and right edge of last bin. In this case, bins is returned unmodified.

backend [str, default None] Backend to use instead of the backend specified in the option `plotting.backend`. For instance, ‘matplotlib’. Alternatively, to specify the `plotting.backend` for the whole session, set `pd.options.plotting.backend`.

New in version 1.0.0.

****kwargs** To be passed to the actual plotting function.

Returns

`matplotlib.AxesSubplot` A histogram plot.

See also:

`matplotlib.axes.Axes.hist` Plot a histogram using matplotlib.

pandas.Series.idxmax

`Series.idxmax(self, axis=0, skipna=True, *args, **kwargs)`

Return the row label of the maximum value.

If multiple values equal the maximum, the first row label with that value is returned.

Parameters

axis [int, default 0] For compatibility with DataFrame.idxmax. Redundant for application on Series.

skipna [bool, default True] Exclude NA/null values. If the entire Series is NA, the result will be NA.

***args, **kwargs** Additional arguments and keywords have no effect but might be accepted for compatibility with NumPy.

Returns

`Index` Label of the maximum value.

Raises

`ValueError` If the Series is empty.

See also:

`numpy.argmax` Return indices of the maximum values along the given axis.

`DataFrame.idxmax` Return index of first occurrence of maximum over requested axis.

`Series.idxmin` Return index *label* of the first occurrence of minimum of values.

Notes

This method is the Series version of `ndarray.argmax`. This method returns the label of the maximum, while `ndarray.argmax` returns the position. To get the position, use `series.values.argmax()`.

Examples

```
>>> s = pd.Series(data=[1, None, 4, 3, 4],  
...                  index=['A', 'B', 'C', 'D', 'E'])  
>>> s  
A    1.0  
B    NaN  
C    4.0  
D    3.0  
E    4.0  
dtype: float64
```

```
>>> s.idxmax()  
'C'
```

If `skipna` is False and there is an NA value in the data, the function returns nan.

```
>>> s.idxmax(skipna=False)  
nan
```

pandas.Series.idxmin

`Series.idxmin(self, axis=0, skipna=True, *args, **kwargs)`

Return the row label of the minimum value.

If multiple values equal the minimum, the first row label with that value is returned.

Parameters

`axis` [int, default 0] For compatibility with DataFrame.idxmin. Redundant for application on Series.

`skipna` [bool, default True] Exclude NA/null values. If the entire Series is NA, the result will be NA.

`*args, **kwargs` Additional arguments and keywords have no effect but might be accepted for compatibility with NumPy.

Returns

`Index` Label of the minimum value.

Raises

`ValueError` If the Series is empty.

See also:

`numpy.argmin` Return indices of the minimum values along the given axis.

`DataFrame.idxmin` Return index of first occurrence of minimum over requested axis.

`Series.idxmax` Return index *label* of the first occurrence of maximum of values.

Notes

This method is the Series version of `ndarray.argmin`. This method returns the label of the minimum, while `ndarray.argmin` returns the position. To get the position, use `series.values.argmax()`.

Examples

```
>>> s = pd.Series(data=[1, None, 4, 1],  
...                  index=['A', 'B', 'C', 'D'])  
>>> s  
A    1.0  
B    NaN  
C    4.0  
D    1.0  
dtype: float64
```

```
>>> s.idxmin()  
'A'
```

If `skipna` is False and there is an NA value in the data, the function returns nan.

```
>>> s.idxmin(skipna=False)  
nan
```

pandas.Series.infer_objects

`Series.infer_objects(self: ~FrameOrSeries) → ~FrameOrSeries`

Attempt to infer better dtypes for object columns.

Attempts soft conversion of object-dtyped columns, leaving non-object and unconvertible columns unchanged. The inference rules are the same as during normal Series/DataFrame construction.

New in version 0.21.0.

Returns

`converted` [same type as input object]

See also:

`to_datetime` Convert argument to datetime.

`to_timedelta` Convert argument to timedelta.

`to_numeric` Convert argument to numeric type.

`convert_dtypes` Convert argument to best possible dtype.

Examples

```
>>> df = pd.DataFrame({ "A": [ "a", 1, 2, 3 ] })
>>> df = df.iloc[1:]
>>> df
   A
1  1
2  2
3  3
```

```
>>> df.dtypes
A    object
dtype: object
```

```
>>> df.infer_objects().dtypes
A    int64
dtype: object
```

pandas.Series.interpolate

`Series.interpolate(self, method='linear', axis=0, limit=None, inplace=False, limit_direction='forward', limit_area=None, downcast=None, **kwargs)`
Interpolate values according to different methods.

Please note that only `method='linear'` is supported for DataFrame/Series with a MultiIndex.

Parameters

method [str, default ‘linear’] Interpolation technique to use. One of:

- ‘linear’: Ignore the index and treat the values as equally spaced. This is the only method supported on MultiIndexes.
- ‘time’: Works on daily and higher resolution data to interpolate given length of interval.
- ‘index’, ‘values’: use the actual numerical values of the index.
- ‘pad’: Fill in NaNs using existing values.
- ‘nearest’, ‘zero’, ‘slinear’, ‘quadratic’, ‘cubic’, ‘spline’, ‘barycentric’, ‘polynomial’: Passed to `scipy.interpolate.interp1d`. These methods use the numerical values of the index. Both ‘polynomial’ and ‘spline’ require that you also specify an `order` (int), e.g. `df.interpolate(method='polynomial', order=5)`.
- ‘krogh’, ‘piecewise_polynomial’, ‘spline’, ‘pchip’, ‘akima’: Wrappers around the SciPy interpolation methods of similar names. See *Notes*.
- ‘from_derivatives’: Refers to `scipy.interpolate.BPoly.from_derivatives` which replaces ‘piecewise_polynomial’ interpolation method in scipy 0.18.

axis [{0 or ‘index’, 1 or ‘columns’, None}, default None] Axis to interpolate along.

limit [int, optional] Maximum number of consecutive NaNs to fill. Must be greater than 0.

inplace [bool, default False] Update the data in place if possible.

limit_direction [{‘forward’, ‘backward’, ‘both’}, default ‘forward’] If limit is specified, consecutive NaNs will be filled in this direction.

limit_area [{*None*, ‘inside’, ‘outside’}], default *None* If limit is specified, consecutive NaNs will be filled with this restriction.

- *None*: No fill restriction.
- ‘inside’: Only fill NaNs surrounded by valid values (interpolate).
- ‘outside’: Only fill NaNs outside valid values (extrapolate).

New in version 0.23.0.

downcast [optional, ‘infer’ or *None*, defaults to *None*] Downcast dtypes if possible.

****kwargs** Keyword arguments to pass on to the interpolating function.

Returns

Series or DataFrame Returns the same object type as the caller, interpolated at some or all NaN values.

See also:

[**fillna**](#) Fill missing values using different methods.

[**scipy.interpolate.Akima1DInterpolator**](#) Piecewise cubic polynomials (Akima interpolator).

[**scipy.interpolate.BPoly.from_derivatives**](#) Piecewise polynomial in the Bernstein basis.

[**scipy.interpolate.interp1d**](#) Interpolate a 1-D function.

[**scipy.interpolate.KroghInterpolator**](#) Interpolate polynomial (Krogh interpolator).

[**scipy.interpolate.PchipInterpolator**](#) PCHIP 1-d monotonic cubic interpolation.

[**scipy.interpolate.CubicSpline**](#) Cubic spline data interpolator.

Notes

The ‘krogh’, ‘piecewise_polynomial’, ‘spline’, ‘pchip’ and ‘akima’ methods are wrappers around the respective SciPy implementations of similar names. These use the actual numerical values of the index. For more information on their behavior, see the [SciPy documentation](#) and [SciPy tutorial](#).

Examples

Filling in NaN in a [*Series*](#) via linear interpolation.

```
>>> s = pd.Series([0, 1, np.nan, 3])
>>> s
0    0.0
1    1.0
2    NaN
3    3.0
dtype: float64
>>> s.interpolate()
0    0.0
1    1.0
2    2.0
3    3.0
dtype: float64
```

Filling in NaN in a Series by padding, but filling at most two consecutive NaN at a time.

```
>>> s = pd.Series([np.nan, "single_one", np.nan,
...                  "fill_two_more", np.nan, np.nan, np.nan,
...                  4.71, np.nan])
>>> s
0           NaN
1    single_one
2           NaN
3   fill_two_more
4           NaN
5           NaN
6           NaN
7          4.71
8           NaN
dtype: object
>>> s.interpolate(method='pad', limit=2)
0           NaN
1    single_one
2    single_one
3   fill_two_more
4   fill_two_more
5   fill_two_more
6           NaN
7          4.71
8          4.71
dtype: object
```

Filling in NaN in a Series via polynomial interpolation or splines: Both ‘polynomial’ and ‘spline’ methods require that you also specify an `order` (int).

```
>>> s = pd.Series([0, 2, np.nan, 8])
>>> s.interpolate(method='polynomial', order=2)
0    0.000000
1    2.000000
2    4.666667
3    8.000000
dtype: float64
```

Fill the DataFrame forward (that is, going down) along each column using linear interpolation.

Note how the last entry in column ‘a’ is interpolated differently, because there is no entry after it to use for interpolation. Note how the first entry in column ‘b’ remains NaN, because there is no entry before it to use for interpolation.

```
>>> df = pd.DataFrame([(0.0, np.nan, -1.0, 1.0),
...                      (np.nan, 2.0, np.nan, np.nan),
...                      (2.0, 3.0, np.nan, 9.0),
...                      (np.nan, 4.0, -4.0, 16.0)],
...                      columns=list('abcd'))
>>> df
   a      b      c      d
0  0.0    NaN -1.0    1.0
1  NaN     2.0    NaN    NaN
2  2.0     3.0    NaN    9.0
3  NaN     4.0   -4.0   16.0
>>> df.interpolate(method='linear', limit_direction='forward', axis=0)
   a      b      c      d
```

(continues on next page)

(continued from previous page)

0	0.0	NaN	-1.0	1.0
1	1.0	2.0	-2.0	5.0
2	2.0	3.0	-3.0	9.0
3	2.0	4.0	-4.0	16.0

Using polynomial interpolation.

```
>>> df['d'].interpolate(method='polynomial', order=2)
0      1.0
1      4.0
2      9.0
3     16.0
Name: d, dtype: float64
```

pandas.Series.isin

`Series.isin(self, values)`

Check whether *values* are contained in Series.

Return a boolean Series showing whether each element in the Series matches an element in the passed sequence of *values* exactly.

Parameters

`values` [set or list-like] The sequence of values to test. Passing in a single string will raise a `TypeError`. Instead, turn a single string into a list of one element.

Returns

`Series` Series of booleans indicating if each element is in values.

Raises

`TypeError`

- If *values* is a string

See also:

`DataFrame.isin` Equivalent method on DataFrame.

Examples

```
>>> s = pd.Series(['lama', 'cow', 'lama', 'beetle', 'lama',
...                 'hippo'], name='animal')
>>> s.isin(['cow', 'lama'])
0      True
1      True
2      True
3     False
4      True
5     False
Name: animal, dtype: bool
```

Passing a single string as `s.isin('lama')` will raise an error. Use a list of one element instead:

```
>>> s.isin(['lama'])
0      True
1     False
2      True
3     False
4      True
5     False
Name: animal, dtype: bool
```

pandas.Series.isna

`Series.isna(self)`

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as None or numpy.NaN, gets mapped to True values. Everything else gets mapped to False values. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`).

Returns

`Series` Mask of bool values for each element in Series that indicates whether an element is not an NA value.

See also:

`Series.isnull` Alias of isna.

`Series.notna` Boolean inverse of isna.

`Series.dropna` Omit axes labels with missing values.

`isna` Top-level isna.

Examples

Show which entries in a DataFrame are NA.

```
>>> df = pd.DataFrame({'age': [5, 6, np.nan],
...                     'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                             pd.Timestamp('1940-04-25')],
...                     'name': ['Alfred', 'Batman', ''],
...                     'toy': [None, 'Batmobile', 'Joker']})
>>> df
   age      born     name      toy
0  5.0      NaT    Alfred     None
1  6.0 1939-05-27    Batman  Batmobile
2  NaN 1940-04-25        Joker
```

```
>>> df.isna()
      age      born     name      toy
0  False     True    False     True
1  False    False    False    False
2   True    False    False    False
```

Show which entries in a Series are NA.

```
>>> ser = pd.Series([5, 6, np.nan])
>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64
```

```
>>> ser.isna()
0    False
1    False
2     True
dtype: bool
```

pandas.Series.isnull

Series.isnull(self)
Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as None or numpy.NaN, gets mapped to True values. Everything else gets mapped to False values. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True).

Returns

Series Mask of bool values for each element in Series that indicates whether an element is not an NA value.

See also:

Series.isnull Alias of isna.

Series.notna Boolean inverse of isna.

Series.dropna Omit axes labels with missing values.

isna Top-level isna.

Examples

Show which entries in a DataFrame are NA.

```
>>> df = pd.DataFrame({'age': [5, 6, np.nan],
...                     'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                             pd.Timestamp('1940-04-25')],
...                     'name': ['Alfred', 'Batman', ''],
...                     'toy': [None, 'Batmobile', 'Joker']})
>>> df
   age      born     name       toy
0  5.0      NaT  Alfred      None
1  6.0  1939-05-27  Batman  Batmobile
2  NaN  1940-04-25        ''      Joker
```

```
>>> df.isna()
   age      born     name       toy
```

(continues on next page)

(continued from previous page)

```
0  False   True  False   True
1  False   False  False  False
2   True   False  False  False
```

Show which entries in a Series are NA.

```
>>> ser = pd.Series([5, 6, np.nan])
>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64
```

```
>>> ser.isna()
0    False
1    False
2     True
dtype: bool
```

pandas.Series.item

`Series.item(self)`

Return the first element of the underlying data as a python scalar.

Returns

scalar The first element of %(klass)s.

Raises

ValueError If the data is not length-1.

pandas.Series.items

`Series.items(self)`

Lazily iterate over (index, value) tuples.

This method returns an iterable tuple (index, value). This is convenient if you want to create a lazy iterator.

Returns

iterable Iterable of tuples containing the (index, value) pairs from a Series.

See also:

`DataFrame.items` Iterate over (column name, Series) pairs.

`DataFrame.iterrows` Iterate over DataFrame rows as (index, Series) pairs.

Examples

```
>>> s = pd.Series(['A', 'B', 'C'])
>>> for index, value in s.items():
...     print(f"Index : {index}, Value : {value}")
Index : 0, Value : A
Index : 1, Value : B
Index : 2, Value : C
```

pandas.Series.iteritems

`Series.iteritems (self)`

Lazily iterate over (index, value) tuples.

This method returns an iterable tuple (index, value). This is convenient if you want to create a lazy iterator.

Returns

iterable Iterable of tuples containing the (index, value) pairs from a Series.

See also:

`DataFrame.items` Iterate over (column name, Series) pairs.

`DataFrame.iterrows` Iterate over DataFrame rows as (index, Series) pairs.

Examples

```
>>> s = pd.Series(['A', 'B', 'C'])
>>> for index, value in s.items():
...     print(f"Index : {index}, Value : {value}")
Index : 0, Value : A
Index : 1, Value : B
Index : 2, Value : C
```

pandas.Series.keys

`Series.keys (self)`

Return alias for index.

Returns

Index Index of the Series.

pandas.Series.kurt

`Series.kurt(self, axis=None, skipna=None, level=None, numeric_only=None, **kwargs)`
Return unbiased kurtosis over requested axis.

Kurtosis obtained using Fisher's definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1.

Parameters

axis [{index (0)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)

pandas.Series.kurtosis

`Series.kurtosis(self, axis=None, skipna=None, level=None, numeric_only=None, **kwargs)`
Return unbiased kurtosis over requested axis.

Kurtosis obtained using Fisher's definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1.

Parameters

axis [{index (0)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)

pandas.Series.last

`Series.last(self: ~FrameOrSeries, offset) → ~FrameOrSeries`
Method to subset final periods of time series data based on a date offset.

Parameters

offset [str, DateOffset, dateutil.relativedelta]

Returns

subset [same type as caller]

Raises

TypeError If the index is not a `DatetimeIndex`

See also:

`first` Select initial periods of time series based on a date offset.

`at_time` Select values at a particular time of the day.

`between_time` Select values between particular times of the day.

Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
          A
2018-04-09  1
2018-04-11  2
2018-04-13  3
2018-04-15  4
```

Get the rows for the last 3 days:

```
>>> ts.last('3D')
          A
2018-04-13  3
2018-04-15  4
```

Notice the data for 3 last calendar days were returned, not the last 3 observed days in the dataset, and therefore data for 2018-04-11 was not returned.

pandas.Series.last_valid_index

`Series.last_valid_index(self)`
Return index for last non-NA/null value.

Returns

`scalar` [type of index]

Notes

If all elements are non-NA/null, returns None. Also returns None for empty Series/DataFrame.

pandas.Series.le

`Series.le (self, other, level=None, fill_value=None, axis=0)`

Return Less than or equal to of series and other, element-wise (binary operator *le*).

Equivalent to `series <= other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

`Series.None`

pandas.Series.lt

`Series.lt (self, other, level=None, fill_value=None, axis=0)`

Return Less than of series and other, element-wise (binary operator *lt*).

Equivalent to `series < other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

`Series.None`

pandas.Series.mad

`Series.mad(self, axis=None, skipna=None, level=None)`

Return the mean absolute deviation of the values for the requested axis.

Parameters

axis [{index (0)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)

pandas.Series.map

`Series.map(self, arg, na_action=None)`

Map values of Series according to input correspondence.

Used for substituting each value in a Series with another value, that may be derived from a function, a dict or a `Series`.

Parameters

arg [function, collections.abc.Mapping subclass or Series] Mapping correspondence.

na_action [{None, ‘ignore’}, default None] If ‘ignore’, propagate NaN values, without passing them to the mapping correspondence.

Returns

Series Same index as caller.

See also:

`Series.apply` For applying more complex functions on a Series.

`DataFrame.apply` Apply a function row-/column-wise.

`DataFrame.applymap` Apply a function elementwise on a whole DataFrame.

Notes

When `arg` is a dictionary, values in Series that are not in the dictionary (as keys) are converted to NaN. However, if the dictionary is a dict subclass that defines `__missing__` (i.e. provides a method for default values), then this default is used rather than NaN.

Examples

```
>>> s = pd.Series(['cat', 'dog', np.nan, 'rabbit'])
>>> s
0      cat
1      dog
2      NaN
3    rabbit
dtype: object
```

map accepts a dict or a Series. Values that are not found in the dict are converted to NaN, unless the dict has a default value (e.g. defaultdict):

```
>>> s.map({'cat': 'kitten', 'dog': 'puppy'})
0    kitten
1    puppy
2      NaN
3      NaN
dtype: object
```

It also accepts a function:

```
>>> s.map('I am a {}'.format)
0    I am a cat
1    I am a dog
2    I am a nan
3    I am a rabbit
dtype: object
```

To avoid applying the function to missing values (and keep them as NaN) na_action='ignore' can be used:

```
>>> s.map('I am a {}'.format, na_action='ignore')
0    I am a cat
1    I am a dog
2      NaN
3    I am a rabbit
dtype: object
```

pandas.Series.mask

`Series.mask(self, cond, other=nan, inplace=False, axis=None, level=None, errors='raise', try_cast=False)`

Replace values where the condition is True.

Parameters

cond [bool Series/DataFrame, array-like, or callable] Where *cond* is False, keep the original value. Where True, replace with corresponding value from *other*. If *cond* is callable, it is computed on the Series/DataFrame and should return boolean Series/DataFrame or array. The callable must not change input Series/DataFrame (though pandas doesn't check it).

other [scalar, Series/DataFrame, or callable] Entries where *cond* is True are replaced with corresponding value from *other*. If *other* is callable, it is computed on the Series/DataFrame and should return scalar or Series/DataFrame. The callable must not change input Series/DataFrame (though pandas doesn't check it).

inplace [bool, default False] Whether to perform the operation in place on the data.

axis [int, default None] Alignment axis if needed.

level [int, default None] Alignment level if needed.

errors [str, {'raise', 'ignore'}, default 'raise'] Note that currently this parameter won't affect the results and will always coerce to a suitable dtype.

- 'raise' : allow exceptions to be raised.
- 'ignore' : suppress exceptions. On error return original object.

try_cast [bool, default False] Try to cast the result back to the input type (if possible).

Returns

Same type as caller

See also:

`DataFrame.where()` Return an object of same shape as self.

Notes

The mask method is an application of the if-then idiom. For each element in the calling DataFrame, if cond is `False` the element is used; otherwise the corresponding element from the DataFrame other is used.

The signature for `DataFrame.where()` differs from `numpy.where()`. Roughly `df1.where(m, df2)` is equivalent to `np.where(m, df1, df2)`.

For further details and examples see the mask documentation in [indexing](#).

Examples

```
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0      NaN
1      1.0
2      2.0
3      3.0
4      4.0
dtype: float64
```

```
>>> s.mask(s > 0)
0      0.0
1      NaN
2      NaN
3      NaN
4      NaN
dtype: float64
```

```
>>> s.where(s > 1, 10)
0      10
1      10
2      2
3      3
```

(continues on next page)

(continued from previous page)

```
4      4
dtype: int64

>>> df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=[ 'A', 'B'])
>>> df
   A    B
0  0    1
1  2    3
2  4    5
3  6    7
4  8    9
>>> m = df % 3 == 0
>>> df.where(m, -df)
   A    B
0  0   -1
1 -2    3
2 -4   -5
3  6   -7
4 -8    9
>>> df.where(m, -df) == np.where(m, df, -df)
   A    B
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True
>>> df.where(m, -df) == df.mask(~m, -df)
   A    B
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True
```

pandas.Series.max

Series .**max** (*self, axis=None, skipna=None, level=None, numeric_only=None, **kwargs*)

Return the maximum of the values for the requested axis.

If you want the *index* of the maximum, use `idxmax`. This is the equivalent of the `numpy.ndarray` method `argmax`.

Parameters

axis [{index (0)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)**See also:**`Series.sum` Return the sum.`Series.min` Return the minimum.`Series.max` Return the maximum.`Series.idxmin` Return the index of the minimum.`Series.idxmax` Return the index of the maximum.`DataFrame.sum` Return the sum over the requested axis.`DataFrame.min` Return the minimum over the requested axis.`DataFrame.max` Return the maximum over the requested axis.`DataFrame.idxmin` Return the index of the minimum over the requested axis.`DataFrame.idxmax` Return the index of the maximum over the requested axis.**Examples**

```
>>> idx = pd.MultiIndex.from_arrays([
...     ['warm', 'warm', 'cold', 'cold'],
...     ['dog', 'falcon', 'fish', 'spider']],
...     names=['blooded', 'animal']),
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded    animal
warm        dog      4
              falcon   2
cold        fish      0
              spider    8
Name: legs, dtype: int64
```

```
>>> s.max()
8
```

Max using level names, as well as indices.

```
>>> s.max(level='blooded')
blooded
warm      4
cold      8
Name: legs, dtype: int64
```

```
>>> s.max(level=0)
blooded
warm      4
cold      8
Name: legs, dtype: int64
```

pandas.Series.mean

`Series.mean(self, axis=None, skipna=None, level=None, numeric_only=None, **kwargs)`
Return the mean of the values for the requested axis.

Parameters

axis [{index (0)}] Axis for the function to be applied on.
skipna [bool, default True] Exclude NA/null values when computing the result.
level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
****kwargs** Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)

pandas.Series.median

`Series.median(self, axis=None, skipna=None, level=None, numeric_only=None, **kwargs)`
Return the median of the values for the requested axis.

Parameters

axis [{index (0)}] Axis for the function to be applied on.
skipna [bool, default True] Exclude NA/null values when computing the result.
level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
****kwargs** Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)

pandas.Series.memory_usage

`Series.memory_usage(self, index=True, deep=False)`
Return the memory usage of the Series.

The memory usage can optionally include the contribution of the index and of elements of *object* dtype.

Parameters

index [bool, default True] Specifies whether to include the memory usage of the Series index.
deep [bool, default False] If True, introspect the data deeply by interrogating *object* dtypes for system-level memory consumption, and include it in the returned value.

Returns

`int` Bytes of memory consumed.

See also:

[`numpy.ndarray nbytes`](#) Total bytes consumed by the elements of the array.

[`DataFrame.memory_usage`](#) Bytes consumed by a DataFrame.

Examples

```
>>> s = pd.Series(range(3))
>>> s.memory_usage()
152
```

Not including the index gives the size of the rest of the data, which is necessarily smaller:

```
>>> s.memory_usage(index=False)
24
```

The memory footprint of *object* values is ignored by default:

```
>>> s = pd.Series(["a", "b"])
>>> s.values
array(['a', 'b'], dtype=object)
>>> s.memory_usage()
144
>>> s.memory_usage(deep=True)
260
```

pandas.Series.min

`Series.min(self, axis=None, skipna=None, level=None, numeric_only=None, **kwargs)`

Return the minimum of the values for the requested axis.

If you want the *index* of the minimum, use `idxmin`. This is the equivalent of the `numpy.ndarray` method `argmin`.

Parameters

`axis` [{index (0)}] Axis for the function to be applied on.

`skipna` [bool, default True] Exclude NA/null values when computing the result.

`level` [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

`numeric_only` [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

`**kwargs` Additional keyword arguments to be passed to the function.

Returns

`scalar or Series (if level specified)`

See also:

[`Series.sum`](#) Return the sum.

`Series.min` Return the minimum.

`Series.max` Return the maximum.

`Series.idxmin` Return the index of the minimum.

`Series.idxmax` Return the index of the maximum.

`DataFrame.sum` Return the sum over the requested axis.

`DataFrame.min` Return the minimum over the requested axis.

`DataFrame.max` Return the maximum over the requested axis.

`DataFrame.idxmin` Return the index of the minimum over the requested axis.

`DataFrame.idxmax` Return the index of the maximum over the requested axis.

Examples

```
>>> idx = pd.MultiIndex.from_arrays([
...     ['warm', 'warm', 'cold', 'cold'],
...     ['dog', 'falcon', 'fish', 'spider']],
...     names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded    animal
warm        dog        4
            falcon     2
cold        fish       0
            spider     8
Name: legs, dtype: int64
```

```
>>> s.min()
0
```

Min using level names, as well as indices.

```
>>> s.min(level='blooded')
blooded
warm      2
cold      0
Name: legs, dtype: int64
```

```
>>> s.min(level=0)
blooded
warm      2
cold      0
Name: legs, dtype: int64
```

pandas.Series.mod

`Series.mod(self, other, level=None, fill_value=None, axis=0)`

Return Modulo of series and other, element-wise (binary operator *mod*).

Equivalent to `series % other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

`other` [Series or scalar value]

`fill_value` [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

`level` [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

`Series` The result of the operation.

See also:

`Series.rmod`

Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.mod(b, fill_value=0)
a    0.0
b    NaN
c    NaN
d    0.0
e    NaN
dtype: float64
```

pandas.Series.mode

`Series.mode(self, dropna=True)`
Return the mode(s) of the dataset.

Always returns Series even if only one value is returned.

Parameters

dropna [bool, default True] Don't consider counts of NaN/NaT.

New in version 0.24.0.

Returns

Series Modes of the Series in sorted order.

pandas.Series.mul

`Series.mul(self, other, level=None, fill_value=None, axis=0)`
Return Multiplication of series and other, element-wise (binary operator *mul*).

Equivalent to `series * other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

`Series.rmul`

Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
```

(continues on next page)

(continued from previous page)

```

dtype: float64
>>> a.multiply(b, fill_value=0)
a    1.0
b    0.0
c    0.0
d    0.0
e    NaN
dtype: float64

```

pandas.Series.multiply

Series.multiply(self, other, level=None, fill_value=None, axis=0)

Return Multiplication of series and other, element-wise (binary operator *mul*).

Equivalent to `series * other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

Series.rmul

Examples

```

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.multiply(b, fill_value=0)
a    1.0
b    0.0
c    0.0

```

(continues on next page)

(continued from previous page)

```
d    0.0
e    NaN
dtype: float64
```

pandas.Series.ne

`Series.ne (self, other, level=None, fill_value=None, axis=0)`

Return Not equal to of series and other, element-wise (binary operator *ne*).

Equivalent to `series != other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

`Series.None`

pandas.Series.nlargest

`Series.nlargest (self, n=5, keep='first')`

Return the largest *n* elements.

Parameters

n [int, default 5] Return this many descending sorted values.

keep [{‘first’, ‘last’, ‘all’}, default ‘first’] When there are duplicate values that cannot all fit in a Series of *n* elements:

- **first** [return the first *n* occurrences in order] of appearance.
- **last** [return the last *n* occurrences in reverse] order of appearance.
- **all** [keep all occurrences. This can result in a Series of] size larger than *n*.

Returns

Series The *n* largest values in the Series, sorted in decreasing order.

See also:

`Series.nsmallest` Get the *n* smallest elements.

`Series.sort_values` Sort Series by values.

`Series.head` Return the first *n* rows.

Notes

Faster than `.sort_values(ascending=False).head(n)` for small n relative to the size of the Series object.

Examples

```
>>> countries_population = {"Italy": 59000000, "France": 65000000,
...                               "Malta": 434000, "Maldives": 434000,
...                               "Brunei": 434000, "Iceland": 337000,
...                               "Nauru": 11300, "Tuvalu": 11300,
...                               "Anguilla": 11300, "Monserat": 5200}
>>> s = pd.Series(countries_population)
>>> s
Italy      59000000
France     65000000
Malta      434000
Maldives   434000
Brunei     434000
Iceland    337000
Nauru      11300
Tuvalu     11300
Anguilla   11300
Monserat   5200
dtype: int64
```

The n largest elements where $n=5$ by default.

```
>>> s.nlargest()
France     65000000
Italy      59000000
Malta      434000
Maldives   434000
Brunei     434000
dtype: int64
```

The n largest elements where $n=3$. Default *keep* value is ‘first’ so Malta will be kept.

```
>>> s.nlargest(3)
France     65000000
Italy      59000000
Malta      434000
dtype: int64
```

The n largest elements where $n=3$ and keeping the last duplicates. Brunei will be kept since it is the last with value 434000 based on the index order.

```
>>> s.nlargest(3, keep='last')
France     65000000
Italy      59000000
Brunei    434000
dtype: int64
```

The n largest elements where $n=3$ with all duplicates kept. Note that the returned Series has five elements due to the three duplicates.

```
>>> s.nlargest(3, keep='all')
France      65000000
Italy       59000000
Malta       434000
Maldives    434000
Brunei     434000
dtype: int64
```

pandas.Series.notna

`Series.notna(self)`

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`). NA values, such as None or numpy.NaN, get mapped to False values.

Returns

`Series` Mask of bool values for each element in Series that indicates whether an element is not an NA value.

See also:

`Series.notnull` Alias of notna.

`Series.isna` Boolean inverse of notna.

`Series.dropna` Omit axes labels with missing values.

`notna` Top-level notna.

Examples

Show which entries in a DataFrame are not NA.

```
>>> df = pd.DataFrame({'age': [5, 6, np.nan],
...                     'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                               pd.Timestamp('1940-04-25')],
...                     'name': ['Alfred', 'Batman', ''],
...                     'toy': [None, 'Batmobile', 'Joker']})
>>> df
   age      born     name      toy
0  5.0      NaT  Alfred      None
1  6.0 1939-05-27   Batman  Batmobile
2  NaN 1940-04-25        Joker
```

```
>>> df.notna()
      age      born     name      toy
0  True  False  True  False
1  True   True  True   True
2 False  True  True   True
```

Show which entries in a Series are not NA.

```
>>> ser = pd.Series([5, 6, np.nan])
>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64
```

```
>>> ser.notna()
0     True
1     True
2    False
dtype: bool
```

pandas.Series.notnull

`Series.notnull(self)`

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`). NA values, such as None or numpy.NaN, get mapped to False values.

Returns

`Series` Mask of bool values for each element in Series that indicates whether an element is not an NA value.

See also:

`Series.notnull` Alias of notna.

`Series.isna` Boolean inverse of notna.

`Series.dropna` Omit axes labels with missing values.

`notna` Top-level notna.

Examples

Show which entries in a DataFrame are not NA.

```
>>> df = pd.DataFrame({'age': [5, 6, np.nan],
...                     'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                             pd.Timestamp('1940-04-25')],
...                     'name': ['Alfred', 'Batman', ''],
...                     'toy': [None, 'Batmobile', 'Joker']})
>>> df
   age      born     name       toy
0  5.0      NaT  Alfred      None
1  6.0  1939-05-27  Batman  Batmobile
2  NaN  1940-04-25        ''      Joker
```

```
>>> df.notna()
   age      born     name       toy
```

(continues on next page)

(continued from previous page)

```
0    True   False   True   False
1    True    True   True    True
2   False   True   True    True
```

Show which entries in a Series are not NA.

```
>>> ser = pd.Series([5, 6, np.nan])
>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64
```

```
>>> ser.notna()
0     True
1     True
2    False
dtype: bool
```

pandas.Series.nsmallest

`Series.nsmallest(self, n=5, keep='first')`

Return the smallest *n* elements.

Parameters

n [int, default 5] Return this many ascending sorted values.

keep [{‘first’, ‘last’, ‘all’}, default ‘first’] When there are duplicate values that cannot all fit in a Series of *n* elements:

- **first** [return the first *n* occurrences in order] of appearance.
- **last** [return the last *n* occurrences in reverse] order of appearance.
- **all** [keep all occurrences. This can result in a Series of] size larger than *n*.

Returns

`Series` The *n* smallest values in the Series, sorted in increasing order.

See also:

`Series.nlargest` Get the *n* largest elements.

`Series.sort_values` Sort Series by values.

`Series.head` Return the first *n* rows.

Notes

Faster than `.sort_values().head(n)` for small `n` relative to the size of the `Series` object.

Examples

```
>>> countries_population = {"Italy": 59000000, "France": 65000000,
...                      "Brunei": 434000, "Malta": 434000,
...                      "Maldives": 434000, "Iceland": 337000,
...                      "Nauru": 11300, "Tuvalu": 11300,
...                      "Anguilla": 11300, "Monserat": 5200}
>>> s = pd.Series(countries_population)
>>> s
Italy      59000000
France     65000000
Brunei     434000
Malta      434000
Maldives   434000
Iceland    337000
Nauru      11300
Tuvalu     11300
Anguilla   11300
Monserat   5200
dtype: int64
```

The `n` smallest elements where `n=5` by default.

```
>>> s.nsmallest()
Monserat    5200
Nauru       11300
Tuvalu      11300
Anguilla    11300
Iceland     337000
dtype: int64
```

The `n` smallest elements where `n=3`. Default `keep` value is ‘first’ so Nauru and Tuvalu will be kept.

```
>>> s.nsmallest(3)
Monserat    5200
Nauru       11300
Tuvalu      11300
dtype: int64
```

The `n` smallest elements where `n=3` and keeping the last duplicates. Anguilla and Tuvalu will be kept since they are the last with value 11300 based on the index order.

```
>>> s.nsmallest(3, keep='last')
Monserat    5200
Anguilla    11300
Tuvalu      11300
dtype: int64
```

The `n` smallest elements where `n=3` with all duplicates kept. Note that the returned Series has four elements due to the three duplicates.

```
>>> s.nsmallest(3, keep='all')
Monserat      5200
Nauru        11300
Tuvalu        11300
Anguilla      11300
dtype: int64
```

pandas.Series.nunique

`Series.nunique(self, dropna=True)`

Return number of unique elements in the object.

Excludes NA values by default.

Parameters

`dropna` [bool, default True] Don't include NaN in the count.

Returns

`int`

See also:

`DataFrame.nunique` Method nunique for DataFrame.

`Series.count` Count non-NA/null observations in the Series.

Examples

```
>>> s = pd.Series([1, 3, 5, 7, 7])
>>> s
0    1
1    3
2    5
3    7
4    7
dtype: int64
```

```
>>> s.nunique()
4
```

pandas.Series.pct_change

`Series.pct_change(self: ~FrameOrSeries, periods=1, fill_method='pad', limit=None, freq=None, **kwargs) → ~FrameOrSeries`

Percentage change between the current and a prior element.

Computes the percentage change from the immediately previous row by default. This is useful in comparing the percentage of change in a time series of elements.

Parameters

`periods` [int, default 1] Periods to shift for forming percent change.

`fill_method` [str, default ‘pad’] How to handle NAs before computing percent changes.

limit [int, default None] The number of consecutive NAs to fill before stopping.
freq [DateOffset, timedelta, or str, optional] Increment to use from time series API (e.g. ‘M’ or BDay()).
****kwargs** Additional keyword arguments are passed into *DataFrame.shift* or *Series.shift*.

Returns

chg [Series or DataFrame] The same type as the calling object.

See also:

Series.diff Compute the difference of two elements in a Series.

DataFrame.diff Compute the difference of two elements in a DataFrame.

Series.shift Shift the index by some number of periods.

DataFrame.shift Shift the index by some number of periods.

Examples**Series**

```
>>> s = pd.Series([90, 91, 85])
>>> s
0    90
1    91
2    85
dtype: int64
```

```
>>> s.pct_change()
0        NaN
1    0.011111
2   -0.065934
dtype: float64
```

```
>>> s.pct_change(periods=2)
0        NaN
1        NaN
2   -0.055556
dtype: float64
```

See the percentage change in a Series where filling NAs with last valid observation forward to next valid.

```
>>> s = pd.Series([90, 91, None, 85])
>>> s
0    90.0
1    91.0
2    NaN
3    85.0
dtype: float64
```

```
>>> s.pct_change(fill_method='ffill')
0        NaN
1    0.011111
2    0.000000
```

(continues on next page)

(continued from previous page)

```
3   -0.065934  
dtype: float64
```

DataFrame

Percentage change in French franc, Deutsche Mark, and Italian lira from 1980-01-01 to 1980-03-01.

```
>>> df = pd.DataFrame({  
...     'FR': [4.0405, 4.0963, 4.3149],  
...     'GR': [1.7246, 1.7482, 1.8519],  
...     'IT': [804.74, 810.01, 860.13]},  
...     index=['1980-01-01', '1980-02-01', '1980-03-01'])  
>>> df  
          FR        GR        IT  
1980-01-01  4.0405  1.7246  804.74  
1980-02-01  4.0963  1.7482  810.01  
1980-03-01  4.3149  1.8519  860.13
```

```
>>> df.pct_change()  
          FR        GR        IT  
1980-01-01    NaN      NaN      NaN  
1980-02-01  0.013810  0.013684  0.006549  
1980-03-01  0.053365  0.059318  0.061876
```

Percentage of change in GOOG and APPL stock volume. Shows computing the percentage change between columns.

```
>>> df = pd.DataFrame({  
...     '2016': [1769950, 30586265],  
...     '2015': [1500923, 40912316],  
...     '2014': [1371819, 41403351]},  
...     index=['GOOG', 'APPL'])  
>>> df  
          2016        2015        2014  
GOOG  1769950  1500923  1371819  
APPL  30586265  40912316  41403351
```

```
>>> df.pct_change(axis='columns')  
          2016        2015        2014  
GOOG    NaN  -0.151997  -0.086016  
APPL    NaN   0.337604   0.012002
```

pandas.Series.pipe

`Series.pipe(self, func, *args, **kwargs)`

Apply `func(self, *args, **kwargs)`.

Parameters

func [function] Function to apply to the Series/DataFrame. `args`, and `kwargs` are passed into `func`. Alternatively a (`callable`, `data_keyword`) tuple where `data_keyword` is a string indicating the keyword of `callable` that expects the Series/DataFrame.

args [iterable, optional] Positional arguments passed into `func`.

kwargs [mapping, optional] A dictionary of keyword arguments passed into `func`.

Returns

object [the return type of `func`.]

See also:

`DataFrame.apply`

`DataFrame.applymap`

`Series.map`

Notes

Use `.pipe` when chaining together functions that expect Series, DataFrames or GroupBy objects. Instead of writing

```
>>> f(g(h(df), arg1=a), arg2=b, arg3=c)
```

You can write

```
>>> (df.pipe(h)
...     .pipe(g, arg1=a)
...     .pipe(f, arg2=b, arg3=c)
... )
```

If you have a function that takes the data as (say) the second argument, pass a tuple indicating which keyword expects the data. For example, suppose `f` takes its data as `arg2`:

```
>>> (df.pipe(h)
...     .pipe(g, arg1=a)
...     .pipe((f, 'arg2'), arg1=a, arg3=c)
... )
```

pandas.Series.plot

`Series.plot(self, *args, **kwargs)`

Make plots of Series or DataFrame.

Uses the backend specified by the option `plotting.backend`. By default, matplotlib is used.

Parameters

data [Series or DataFrame] The object for which the method is called.

x [label or position, default None] Only used if data is a DataFrame.

y [label, position or list of label, positions, default None] Allows plotting of one column versus another. Only used if data is a DataFrame.

kind [str] The kind of plot to produce:

- ‘line’ : line plot (default)
- ‘bar’ : vertical bar plot
- ‘barh’ : horizontal bar plot
- ‘hist’ : histogram

- ‘box’ : boxplot
- ‘kde’ : Kernel Density Estimation plot
- ‘density’ : same as ‘kde’
- ‘area’ : area plot
- ‘pie’ : pie plot
- ‘scatter’ : scatter plot
- ‘hexbin’ : hexbin plot.

figsize [a tuple (width, height) in inches]

use_index [bool, default True] Use index as ticks for x axis.

title [str or list] Title to use for the plot. If a string is passed, print the string at the top of the figure. If a list is passed and *subplots* is True, print each item in the list above the corresponding subplot.

grid [bool, default None (matlab style default)] Axis grid lines.

legend [bool or {‘reverse’}] Place legend on axis subplots.

style [list or dict] The matplotlib line style per column.

logx [bool or ‘sym’, default False] Use log scaling or symlog scaling on x axis. ... versionchanged:: 0.25.0

logy [bool or ‘sym’ default False] Use log scaling or symlog scaling on y axis. ... versionchanged:: 0.25.0

loglog [bool or ‘sym’, default False] Use log scaling or symlog scaling on both x and y axes. ... versionchanged:: 0.25.0

xticks [sequence] Values to use for the xticks.

yticks [sequence] Values to use for the yticks.

xlim [2-tuple/list]

ylim [2-tuple/list]

rot [int, default None] Rotation for ticks (xticks for vertical, yticks for horizontal plots).

fontsize [int, default None] Font size for xticks and yticks.

colormap [str or matplotlib colormap object, default None] Colormap to select colors from. If string, load colormap with that name from matplotlib.

colorbar [bool, optional] If True, plot colorbar (only relevant for ‘scatter’ and ‘hexbin’ plots).

position [float] Specify relative alignments for bar plot layout. From 0 (left/bottom-end) to 1 (right/top-end). Default is 0.5 (center).

table [bool, Series or DataFrame, default False] If True, draw a table using the data in the DataFrame and the data will be transposed to meet matplotlib’s default layout. If a Series or DataFrame is passed, use passed data to draw a table.

yerr [DataFrame, Series, array-like, dict and str] See [Plotting with Error Bars](#) for detail.

xerr [DataFrame, Series, array-like, dict and str] Equivalent to yerr.

mark_right [bool, default True] When using a secondary_y axis, automatically mark the column labels with “(right)” in the legend.

include_bool [bool, default is False] If True, boolean values can be plotted.

backend [str, default None] Backend to use instead of the backend specified in the option `plotting.backend`. For instance, ‘matplotlib’. Alternatively, to specify the `plotting.backend` for the whole session, set `pd.options.plotting.backend`.

New in version 1.0.0.

****kwargs** Options to pass to matplotlib plotting method.

Returns

matplotlib.axes.Axes or numpy.ndarray of them If the backend is not the default matplotlib one, the return value will be the object returned by the backend.

Notes

- See matplotlib documentation online for more on this subject
- If `kind = ‘bar’` or `‘barh’`, you can specify relative alignments for bar plot layout by `position` keyword. From 0 (left/bottom-end) to 1 (right/top-end). Default is 0.5 (center)

pandas.Series.pop

`Series.pop(self: ~FrameOrSeries, item) → ~FrameOrSeries`

Return item and drop from frame. Raise KeyError if not found.

Parameters

item [str] Label of column to be popped.

Returns

`Series`

Examples

```
>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
...                     ('parrot', 'bird', 24.0),
...                     ('lion', 'mammal', 80.5),
...                     ('monkey', 'mammal', np.nan)],
...                     columns=('name', 'class', 'max_speed'))
>>> df
   name    class  max_speed
0  falcon     bird      389.0
1  parrot     bird       24.0
2    lion  mammal       80.5
3  monkey  mammal        NaN
```

```
>>> df.pop('class')
0      bird
1      bird
2  mammal
3  mammal
Name: class, dtype: object
```

```
>>> df
      name  max_speed
0  falcon      389.0
1  parrot       24.0
2    lion        80.5
3  monkey       NaN
```

pandas.Series.pow

`Series.pow(self, other, level=None, fill_value=None, axis=0)`

Return Exponential power of series and other, element-wise (binary operator *pow*).

Equivalent to `series ** other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

Returns

Series The result of the operation.

See also:

`Series.rpow`

Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.pow(b, fill_value=0)
a    1.0
b    1.0
c    1.0
d    0.0
```

(continues on next page)

(continued from previous page)

```
e      NaN
dtype: float64
```

pandas.Series.prod

`Series.prod(self, axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs)`

Return the product of the values for the requested axis.

Parameters

axis [{index (0)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

min_count [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

New in version 0.22.0: Added with the default being 0. This means the sum of an all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)

Examples

By default, the product of an empty or all-NA Series is 1

```
>>> pd.Series([]).prod()
1.0
```

This can be controlled with the `min_count` parameter

```
>>> pd.Series([]).prod(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```
>>> pd.Series([np.nan]).prod()
1.0
```

```
>>> pd.Series([np.nan]).prod(min_count=1)
nan
```

pandas.Series.product

```
Series .product (self, axis=None, skipna=None, level=None, numeric_only=None, min_count=0,  
                 **kwargs)
```

Return the product of the values for the requested axis.

Parameters

axis [{index (0)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

min_count [int, default 0] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

New in version 0.22.0: Added with the default being 0. This means the sum of an all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)

Examples

By default, the product of an empty or all-NA Series is 1

```
>>> pd.Series([]).prod()  
1.0
```

This can be controlled with the min_count parameter

```
>>> pd.Series([]).prod(min_count=1)  
nan
```

Thanks to the skipna parameter, min_count handles all-NA and empty series identically.

```
>>> pd.Series([np.nan]).prod()  
1.0
```

```
>>> pd.Series([np.nan]).prod(min_count=1)  
nan
```

pandas.Series.quantile

`Series.quantile(self, q=0.5, interpolation='linear')`

Return value at the given quantile.

Parameters

q [float or array-like, default 0.5 (50% quantile)] The quantile(s) to compute, which can lie in range: $0 \leq q \leq 1$.

interpolation [{‘linear’, ‘lower’, ‘higher’, ‘midpoint’, ‘nearest’}] This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points i and j :

- linear: $i + (j - i) * fraction$, where $fraction$ is the fractional part of the index surrounded by i and j .
- lower: i .
- higher: j .
- nearest: i or j whichever is nearest.
- midpoint: $(i + j) / 2$.

Returns

float or Series If q is an array, a Series will be returned where the index is q and the values are the quantiles, otherwise a float will be returned.

See also:

`core.window.Rolling.quantile`

`numpy.percentile`

Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s.quantile(.5)
2.5
>>> s.quantile([.25, .5, .75])
0.25    1.75
0.50    2.50
0.75    3.25
dtype: float64
```

pandas.Series.radd

`Series.radd(self, other, level=None, fill_value=None, axis=0)`

Return Addition of series and other, element-wise (binary operator `radd`).

Equivalent to `other + series`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

[`Series.add`](#)

Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64
```

[`pandas.Series.rank`](#)

`Series.rank(self: ~FrameOrSeries, axis=0, method: str = 'average', numeric_only: Union[bool, NoneType] = None, na_option: str = 'keep', ascending: bool = True, pct: bool = False) → ~FrameOrSeries`

Compute numerical data ranks (1 through n) along axis.

By default, equal values are assigned a rank that is the average of the ranks of those values.

Parameters

axis [{0 or ‘index’, 1 or ‘columns’}, default 0] Index to direct ranking.

method [{‘average’, ‘min’, ‘max’, ‘first’, ‘dense’}, default ‘average’] How to rank the group of records that have the same value (i.e. ties):

- average: average rank of the group

- min: lowest rank in the group
- max: highest rank in the group
- first: ranks assigned in order they appear in the array
- dense: like ‘min’, but rank always increases by 1 between groups.

numeric_only [bool, optional] For DataFrame objects, rank only numeric columns if set to True.

na_option [{‘keep’, ‘top’, ‘bottom’}, default ‘keep’] How to rank NaN values:

- keep: assign NaN rank to NaN values
- top: assign smallest rank to NaN values if ascending
- bottom: assign highest rank to NaN values if ascending.

ascending [bool, default True] Whether or not the elements should be ranked in ascending order.

pct [bool, default False] Whether or not to display the returned rankings in percentile form.

Returns

same type as caller Return a Series or DataFrame with data ranks as values.

See also:

[core.groupby.GroupBy.rank](#) Rank of values within each group.

Examples

```
>>> df = pd.DataFrame(data={'Animal': ['cat', 'penguin', 'dog',
...                                     'spider', 'snake'],
...                         'Number_legs': [4, 2, 4, 8, np.nan]})

>>> df
   Animal  Number_legs
0      cat         4.0
1  penguin         2.0
2      dog         4.0
3     spider         8.0
4     snake        NaN
```

The following example shows how the method behaves with the above parameters:

- default_rank: this is the default behaviour obtained without using any parameter.
- max_rank: setting `method = ‘max’` the records that have the same values are ranked using the highest rank (e.g.: since ‘cat’ and ‘dog’ are both in the 2nd and 3rd position, rank 3 is assigned.)
- NA_bottom: choosing `na_option = ‘bottom’`, if there are records with NaN values they are placed at the bottom of the ranking.
- pct_rank: when setting `pct = True`, the ranking is expressed as percentile rank.

```
>>> df['default_rank'] = df['Number_legs'].rank()
>>> df['max_rank'] = df['Number_legs'].rank(method='max')
>>> df['NA_bottom'] = df['Number_legs'].rank(na_option='bottom')
>>> df['pct_rank'] = df['Number_legs'].rank(pct=True)
```

(continues on next page)

(continued from previous page)

	Animal	Number_legs	default_rank	max_rank	NA_bottom	pct_rank
0	cat	4.0	2.5	3.0	2.5	0.625
1	penguin	2.0	1.0	1.0	1.0	0.250
2	dog	4.0	2.5	3.0	2.5	0.625
3	spider	8.0	4.0	4.0	4.0	1.000
4	snake	NaN	NaN	NaN	5.0	NaN

pandas.Series.ravel

`Series.ravel (self, order='C')`

Return the flattened underlying data as an ndarray.

Returns

`numpy.ndarray or ndarray-like` Flattened data of the Series.

See also:

`numpy.ndarray.ravel`

pandas.Series.rdiv

`Series.rdiv (self, other, level=None, fill_value=None, axis=0)`

Return Floating division of series and other, element-wise (binary operator *rtruediv*).

Equivalent to `other / series`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

`other` [Series or scalar value]

`fill_value` [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

`level` [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

Returns

`Series` The result of the operation.

See also:

`Series.truediv`

Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.divide(b, fill_value=0)
a    1.0
b    inf
c    inf
d    0.0
e    NaN
dtype: float64
```

pandas.Series.rdivmod

`Series.rdivmod(self, other, level=None, fill_value=None, axis=0)`

Return Integer division and modulo of series and other, element-wise (binary operator `rdivmod`).

Equivalent to `other.divmod` series, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

Returns

Series The result of the operation.

See also:

`Series.divmod`

`pandas.Series.reindex`

`Series.reindex(self, index=None, **kwargs)`

Conform Series to new index with optional filling logic.

Places NA/NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and `copy=False`.

Parameters

index [array-like, optional] New labels / index to conform to, should be specified using keywords. Preferably an Index object to avoid duplicating data.

method [{None, ‘backfill’/‘bfill’, ‘pad’/‘ffill’, ‘nearest’}] Method to use for filling holes in reindexed DataFrame. Please note: this is only applicable to DataFrames/Series with a monotonically increasing/decreasing index.

- None (default): don’t fill gaps
- pad / ffill: Propagate last valid observation forward to next valid.
- backfill / bfill: Use next valid observation to fill gap.
- nearest: Use nearest valid observations to fill gap.

copy [bool, default True] Return a new object, even if the passed indexes are the same.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [scalar, default np.NaN] Value to use for missing values. Defaults to NaN, but can be any “compatible” value.

limit [int, default None] Maximum number of consecutive elements to forward or backward fill.

tolerance [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations must satisfy the equation `abs(index[indexer] - target) <= tolerance`.

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index’s type.

New in version 0.21.0: (list-like tolerance)

Returns

Series with changed index.

See also:

`DataFrame.set_index` Set row labels.

`DataFrame.reset_index` Remove row labels or move them to new columns.

`DataFrame.reindex_like` Change to same indices as other DataFrame.

Examples

`DataFrame.reindex` supports two calling conventions

- `(index=index_labels, columns=column_labels, ...)`
- `(labels, axis={'index', 'columns'}, ...)`

We *highly* recommend using keyword arguments to clarify your intent.

Create a dataframe with some fictional data.

```
>>> index = ['Firefox', 'Chrome', 'Safari', 'IE10', 'Konqueror']
>>> df = pd.DataFrame({'http_status': [200, 200, 404, 404, 301],
...                     'response_time': [0.04, 0.02, 0.07, 0.08, 1.0]},
...                     index=index)
>>> df
      http_status  response_time
Firefox          200           0.04
Chrome           200           0.02
Safari            404           0.07
IE10              404           0.08
Konqueror         301           1.00
```

Create a new index and reindex the dataframe. By default values in the new index that do not have corresponding records in the dataframe are assigned NaN.

```
>>> new_index = ['Safari', 'Iceweasel', 'Comodo Dragon', 'IE10',
...               'Chrome']
>>> df.reindex(new_index)
      http_status  response_time
Safari           404.0           0.07
Iceweasel         NaN             NaN
Comodo Dragon    NaN             NaN
IE10              404.0           0.08
Chrome            200.0           0.02
```

We can fill in the missing values by passing a value to the keyword `fill_value`. Because the index is not monotonically increasing or decreasing, we cannot use arguments to the keyword method to fill the NaN values.

```
>>> df.reindex(new_index, fill_value=0)
      http_status  response_time
Safari           404           0.07
Iceweasel         0             0.00
Comodo Dragon    0             0.00
IE10              404           0.08
Chrome            200           0.02
```

```
>>> df.reindex(new_index, fill_value='missing')
      http_status  response_time
Safari           404           0.07
Iceweasel        missing        missing
Comodo Dragon    missing        missing
IE10              404           0.08
Chrome            200           0.02
```

We can also reindex the columns.

```
>>> df.reindex(columns=['http_status', 'user_agent'])
      http_status  user_agent
Firefox          200        NaN
Chrome           200        NaN
Safari            404        NaN
IE10              404        NaN
Konqueror         301        NaN
```

Or we can use “axis-style” keyword arguments

```
>>> df.reindex(['http_status', 'user_agent'], axis="columns")
      http_status  user_agent
Firefox          200        NaN
Chrome           200        NaN
Safari            404        NaN
IE10              404        NaN
Konqueror         301        NaN
```

To further illustrate the filling functionality in `reindex`, we will create a dataframe with a monotonically increasing index (for example, a sequence of dates).

```
>>> date_index = pd.date_range('1/1/2010', periods=6, freq='D')
>>> df2 = pd.DataFrame({"prices": [100, 101, np.nan, 100, 89, 88]}, index=date_index)
...
>>> df2
      prices
2010-01-01    100.0
2010-01-02    101.0
2010-01-03     NaN
2010-01-04    100.0
2010-01-05     89.0
2010-01-06     88.0
```

Suppose we decide to expand the dataframe to cover a wider date range.

```
>>> date_index2 = pd.date_range('12/29/2009', periods=10, freq='D')
>>> df2.reindex(date_index2)
      prices
2009-12-29     NaN
2009-12-30     NaN
2009-12-31     NaN
2010-01-01    100.0
2010-01-02    101.0
2010-01-03     NaN
2010-01-04    100.0
2010-01-05     89.0
2010-01-06     88.0
2010-01-07     NaN
```

The index entries that did not have a value in the original data frame (for example, ‘2009-12-29’) are by default filled with `NaN`. If desired, we can fill in the missing values using one of several options.

For example, to back-propagate the last valid value to fill the `NaN` values, pass `bfill` as an argument to the `method` keyword.

```
>>> df2.reindex(date_index2, method='bfill')
      prices
```

(continues on next page)

(continued from previous page)

2009-12-29	100.0
2009-12-30	100.0
2009-12-31	100.0
2010-01-01	100.0
2010-01-02	101.0
2010-01-03	NaN
2010-01-04	100.0
2010-01-05	89.0
2010-01-06	88.0
2010-01-07	NaN

Please note that the NaN value present in the original dataframe (at index value 2010-01-03) will not be filled by any of the value propagation schemes. This is because filling while reindexing does not look at dataframe values, but only compares the original and desired indexes. If you do want to fill in the NaN values present in the original dataframe, use the `fillna()` method.

See the [user guide](#) for more.

pandas.Series.reindex_like

`Series.reindex_like(self: ~FrameOrSeries, other, method: Union[str, NoneType] = None, copy: bool = True, limit=None, tolerance=None) → ~FrameOrSeries`

Return an object with matching indices as other object.

Conform the object to the same index on all axes. Optional filling logic, placing NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and `copy=False`.

Parameters

other [Object of the same data type] Its row and column indices are used to define the new indices of this object.

method [{None, ‘backfill’/‘bfill’, ‘pad’/‘ffill’, ‘nearest’}] Method to use for filling holes in reindexed DataFrame. Please note: this is only applicable to DataFrames/Series with a monotonically increasing/decreasing index.

- None (default): don’t fill gaps
- pad / ffill: propagate last valid observation forward to next valid
- backfill / bfill: use next valid observation to fill gap
- nearest: use nearest valid observations to fill gap.

copy [bool, default True] Return a new object, even if the passed indexes are the same.

limit [int, default None] Maximum number of consecutive labels to fill for inexact matches.

tolerance [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations must satisfy the equation `abs(index[indexer] - target) <= tolerance`.

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its `dtype` must exactly match the index’s type.

New in version 0.21.0: (list-like tolerance)

Returns

Series or DataFrame Same type as caller, but with changed indices on each axis.

See also:

`DataFrame.set_index` Set row labels.

`DataFrame.reset_index` Remove row labels or move them to new columns.

`DataFrame.reindex` Change to new indices or expand indices.

Notes

Same as calling `.reindex(index=other.index, columns=other.columns, ...)`.

Examples

```
>>> df1 = pd.DataFrame([[24.3, 75.7, 'high'],
...                      [31, 87.8, 'high'],
...                      [22, 71.6, 'medium'],
...                      [35, 95, 'medium']],
...                     columns=['temp_celsius', 'temp_fahrenheit',
...                               'windspeed'],
...                     index=pd.date_range(start='2014-02-12',
...                                         end='2014-02-15', freq='D'))
```

```
>>> df1
      temp_celsius  temp_fahrenheit windspeed
2014-02-12        24.3            75.7     high
2014-02-13        31.0            87.8     high
2014-02-14        22.0            71.6   medium
2014-02-15        35.0            95.0   medium
```

```
>>> df2 = pd.DataFrame([[28, 'low'],
...                      [30, 'low'],
...                      [35.1, 'medium']],
...                     columns=['temp_celsius', 'windspeed'],
...                     index=pd.DatetimeIndex(['2014-02-12', '2014-02-13',
...                                         '2014-02-15']))
```

```
>>> df2
      temp_celsius windspeed
2014-02-12        28.0       low
2014-02-13        30.0       low
2014-02-15        35.1   medium
```

```
>>> df2.reindex_like(df1)
      temp_celsius  temp_fahrenheit windspeed
2014-02-12        28.0            NaN     low
2014-02-13        30.0            NaN     low
2014-02-14         NaN            NaN    NaN
2014-02-15        35.1            NaN   medium
```

pandas.Series.rename

```
Series.rename(self, index=None, *, axis=None, copy=True, inplace=False, level=None, errors='ignore')
```

Alter Series index labels or name.

Function / dict values must be unique (1-to-1). Labels not contained in a dict / Series will be left as-is. Extra labels listed don't throw an error.

Alternatively, change `Series.name` with a scalar value.

See the [user guide](#) for more.

Parameters

`axis` [{0 or “index”}] Unused. Accepted for compatibility with DataFrame method only.

`index` [scalar, hashable sequence, dict-like or function, optional] Functions or dict-like are transformations to apply to the index. Scalar or hashable sequence-like will alter the `Series.name` attribute.

`**kwargs` Additional keyword arguments passed to the function. Only the “`inplace`” keyword is used.

Returns

`Series` Series with index labels or name altered.

See also:

`DataFrame.rename` Corresponding DataFrame method.

`Series.rename_axis` Set the name of the axis.

Examples

```
>>> s = pd.Series([1, 2, 3])
>>> s
0    1
1    2
2    3
dtype: int64
>>> s.rename("my_name")    # scalar, changes Series.name
0    1
1    2
2    3
Name: my_name, dtype: int64
>>> s.rename(lambda x: x ** 2)    # function, changes labels
0    1
1    4
2    9
dtype: int64
>>> s.rename({1: 3, 2: 5})    # mapping, changes labels
0    1
3    2
5    3
dtype: int64
```

`pandas.Series.rename_axis`

```
Series.rename_axis(self, mapper=None, index=None, columns=None, axis=None, copy=True,  
                  inplace=False)
```

Set the name of the axis for the index or columns.

Parameters

mapper [scalar, list-like, optional] Value to set the axis name attribute.

index, columns [scalar, list-like, dict-like or function, optional] A scalar, list-like, dict-like or functions transformations to apply to that axis' values.

Use either `mapper` and `axis` to specify the axis to target with `mapper`, or `index` and/or `columns`.

Changed in version 0.24.0.

axis [{0 or ‘index’, 1 or ‘columns’}, default 0] The axis to rename.

copy [bool, default True] Also copy underlying data.

inplace [bool, default False] Modifies the object directly, instead of creating a new Series or DataFrame.

Returns

Series, DataFrame, or None The same type as the caller or None if `inplace` is True.

See also:

[`Series.rename`](#) Alter Series index labels or name.

[`DataFrame.rename`](#) Alter DataFrame index labels or name.

[`Index.rename`](#) Set new names on index.

Notes

`DataFrame.rename_axis` supports two calling conventions

- (`index=index_mapper, columns=columns_mapper, ...`)
- (`mapper, axis={'index', 'columns'}, ...`)

The first calling convention will only modify the names of the index and/or the names of the Index object that is the columns. In this case, the parameter `copy` is ignored.

The second calling convention will modify the names of the the corresponding index if `mapper` is a list or a scalar. However, if `mapper` is dict-like or a function, it will use the deprecated behavior of modifying the axis *labels*.

We *highly* recommend using keyword arguments to clarify your intent.

Examples

Series

```
>>> s = pd.Series(["dog", "cat", "monkey"])
>>> s
0      dog
1      cat
2    monkey
dtype: object
>>> s.rename_axis("animal")
animal
0      dog
1      cat
2    monkey
dtype: object
```

DataFrame

```
>>> df = pd.DataFrame({ "num_legs": [4, 4, 2],
...                      "num_arms": [0, 0, 2]},
...                      ["dog", "cat", "monkey"])
>>> df
   num_legs  num_arms
dog         4          0
cat         4          0
monkey      2          2
>>> df = df.rename_axis("animal")
>>> df
   num_legs  num_arms
animal
dog         4          0
cat         4          0
monkey      2          2
>>> df = df.rename_axis("limbs", axis="columns")
>>> df
limbs  num_legs  num_arms
animal
dog         4          0
cat         4          0
monkey      2          2
```

MultiIndex

```
>>> df.index = pd.MultiIndex.from_product(([['mammal'],
...                                         ['dog', 'cat', 'monkey']],
...                                         names=['type', 'name']))
>>> df
limbs      num_legs  num_arms
type  name
mammal  dog         4          0
        cat         4          0
        monkey      2          2
```

```
>>> df.rename_axis(index={'type': 'class'})
limbs      num_legs  num_arms
class  name
```

(continues on next page)

(continued from previous page)

mammal	dog	4	0
	cat	4	0
	monkey	2	2

```
>>> df.rename_axis(columns=str.upper)
LIMBS      num_legs  num_arms
type    name
mammal  dog        4          0
        cat        4          0
        monkey     2          2
```

pandas.Series.reorder_levels

`Series.reorder_levels(self, order)`

Rearrange index levels using input order.

May not drop or duplicate levels.

Parameters

`order` [list of int representing new level order] Reference level by number or key.

Returns

`type of caller (new object)`

pandas.Series.repeat

`Series.repeat(self, repeats, axis=None)`

Repeat elements of a Series.

Returns a new Series where each element of the current Series is repeated consecutively a given number of times.

Parameters

`repeats` [int or array of ints] The number of repetitions for each element. This should be a non-negative integer. Repeating 0 times will return an empty Series.

`axis` [None] Must be None. Has no effect but is accepted for compatibility with numpy.

Returns

`Series` Newly created Series with repeated elements.

See also:

[`Index.repeat`](#) Equivalent function for Index.

[`numpy.repeat`](#) Similar method for `numpy.ndarray`.

Examples

```
>>> s = pd.Series(['a', 'b', 'c'])
>>> s
0    a
1    b
2    c
dtype: object
>>> s.repeat(2)
0    a
0    a
1    b
1    b
2    c
2    c
dtype: object
>>> s.repeat([1, 2, 3])
0    a
1    b
1    b
2    c
2    c
2    c
dtype: object
```

pandas.Series.replace

`Series.replace(self, to_replace=None, value=None, inplace=False, limit=None, regex=False, method='pad')`

Replace values given in `to_replace` with `value`.

Values of the Series are replaced with other values dynamically. This differs from updating with `.loc` or `.iloc`, which require you to specify a location to update with some value.

Parameters

`to_replace` [str, regex, list, dict, Series, int, float, or None] How to find the values that will be replaced.

- numeric, str or regex:
 - numeric: numeric values equal to `to_replace` will be replaced with `value`
 - str: string exactly matching `to_replace` will be replaced with `value`
 - regex: regexes matching `to_replace` will be replaced with `value`
- list of str, regex, or numeric:
 - First, if `to_replace` and `value` are both lists, they **must** be the same length.
 - Second, if `regex=True` then all of the strings in **both** lists will be interpreted as regexes otherwise they will match directly. This doesn't matter much for `value` since there are only a few possible substitution regexes you can use.
 - str, regex and numeric rules apply as above.
- dict:
 - Dicts can be used to specify different replacement values for different existing values. For example, `{'a': 'b', 'y': 'z'}` replaces the value 'a' with

‘b’ and ‘y’ with ‘z’. To use a dict in this way the *value* parameter should be *None*.

- For a DataFrame a dict can specify that different values should be replaced in different columns. For example, `{'a': 1, 'b': 'z'}` looks for the value 1 in column ‘a’ and the value ‘z’ in column ‘b’ and replaces these values with whatever is specified in *value*. The *value* parameter should not be *None* in this case. You can treat this as a special case of passing two lists except that you are specifying the column to search in.
 - For a DataFrame nested dictionaries, e.g., `{'a': {'b': np.nan}}`, are read as follows: look in column ‘a’ for the value ‘b’ and replace it with NaN. The *value* parameter should be *None* to use a nested dict in this way. You can nest regular expressions as well. Note that column names (the top-level dictionary keys in a nested dictionary) **cannot** be regular expressions.
- *None*:
 - This means that the *regex* argument must be a string, compiled regular expression, or list, dict, ndarray or Series of such elements. If *value* is also *None* then this **must** be a nested dictionary or Series.

See the examples section for examples of each of these.

value [scalar, dict, list, str, regex, default *None*] Value to replace any values matching *to_replace* with. For a DataFrame a dict of values can be used to specify which value to use for each column (columns not in the dict will not be filled). Regular expressions, strings and lists or dicts of such objects are also allowed.

inplace [bool, default *False*] If True, in place. Note: this will modify any other views on this object (e.g. a column from a DataFrame). Returns the caller if this is True.

limit [int, default *None*] Maximum size gap to forward or backward fill.

regex [bool or same types as *to_replace*, default *False*] Whether to interpret *to_replace* and/or *value* as regular expressions. If this is *True* then *to_replace* **must** be a string. Alternatively, this could be a regular expression or a list, dict, or array of regular expressions in which case *to_replace* must be *None*.

method [{‘pad’, ‘ffill’, ‘bfill’, *None*}] The method to use when for replacement, when *to_replace* is a scalar, list or tuple and *value* is *None*.

Changed in version 0.23.0: Added to DataFrame.

Returns

Series Object after replacement.

Raises

AssertionError

- If *regex* is not a `bool` and *to_replace* is not `None`.

TypeError

- If *to_replace* is a dict and *value* is not a list, dict, ndarray, or Series
- If *to_replace* is *None* and *regex* is not compilable into a regular expression or is a list, dict, ndarray, or Series.
- When replacing multiple `bool` or `datetime64` objects and the arguments to *to_replace* does not match the type of the value being replaced

ValueError

- If a list or an ndarray is passed to `to_replace` and `value` but they are not the same length.

See also:

`Series.fillna` Fill NA values.

`Series.where` Replace values based on boolean condition.

`Series.str.replace` Simple string replacement.

Notes

- Regex substitution is performed under the hood with `re.sub`. The rules for substitution for `re.sub` are the same.
- Regular expressions will only substitute on strings, meaning you cannot provide, for example, a regular expression matching floating point numbers and expect the columns in your frame that have a numeric dtype to be matched. However, if those floating point numbers *are* strings, then you can do this.
- This method has *a lot* of options. You are encouraged to experiment and play with this method to gain intuition about how it works.
- When dict is used as the `to_replace` value, it is like key(s) in the dict are the `to_replace` part and value(s) in the dict are the `value` parameter.

Examples**Scalar `to_replace` and `value`**

```
>>> s = pd.Series([0, 1, 2, 3, 4])
>>> s.replace(0, 5)
0    5
1    1
2    2
3    3
4    4
dtype: int64
```

```
>>> df = pd.DataFrame({'A': [0, 1, 2, 3, 4],
...                     'B': [5, 6, 7, 8, 9],
...                     'C': ['a', 'b', 'c', 'd', 'e']})
>>> df.replace(0, 5)
   A   B   C
0  5   5   a
1  1   6   b
2  2   7   c
3  3   8   d
4  4   9   e
```

List-like `to_replace`

```
>>> df.replace([0, 1, 2, 3], 4)
   A   B   C
0  4   5   a
1  4   6   b
2  4   7   c
3  4   8   d
4  4   9   e
```

```
>>> df.replace([0, 1, 2, 3], [4, 3, 2, 1])
   A   B   C
0  4   5   a
1  3   6   b
2  2   7   c
3  1   8   d
4  4   9   e
```

```
>>> s.replace([1, 2], method='bfill')
0      0
1      3
2      3
3      3
4      4
dtype: int64
```

dict-like `to_replace`

```
>>> df.replace({0: 10, 1: 100})
   A   B   C
0  10  5   a
1  100 6   b
2    2   7   c
3    3   8   d
4    4   9   e
```

```
>>> df.replace({'A': 0, 'B': 5}, 100)
   A   B   C
0  100 100  a
1    1   6   b
2    2   7   c
3    3   8   d
4    4   9   e
```

```
>>> df.replace({'A': {0: 100, 4: 400}})
   A   B   C
0  100  5   a
1    1   6   b
2    2   7   c
3    3   8   d
4  400   9   e
```

Regular expression `to_replace`

```
>>> df = pd.DataFrame({'A': ['bat', 'foo', 'bait'],
...                      'B': ['abc', 'bar', 'xyz']})
>>> df.replace(to_replace=r'^ba.*', value='new', regex=True)
   A     B
```

(continues on next page)

(continued from previous page)

```
0    new    abc
1    foo    new
2   bait    xyz
```

```
>>> df.replace({'A': r'^ba.$'}, {'A': 'new'}, regex=True)
      A      B
0    new    abc
1    foo    bar
2   bait    xyz
```

```
>>> df.replace(regex=r'^ba.$', value='new')
      A      B
0    new    abc
1    foo    new
2   bait    xyz
```

```
>>> df.replace(regex={r'^ba.$': 'new', 'foo': 'xyz'})
      A      B
0    new    abc
1    xyz    new
2   bait    xyz
```

```
>>> df.replace(regex=[r'^ba.$', 'foo'], value='new')
      A      B
0    new    abc
1    new    new
2   bait    xyz
```

Note that when replacing multiple `bool` or `datetime64` objects, the data types in the `to_replace` parameter must match the data type of the value being replaced:

```
>>> df = pd.DataFrame({'A': [True, False, True],
...                      'B': [False, True, False]})
>>> df.replace({'a string': 'new value', True: False}) # raises
Traceback (most recent call last):
...
TypeError: Cannot compare types 'ndarray(dtype=bool)' and 'str'
```

This raises a `TypeError` because one of the dict keys is not of the correct type for replacement.

Compare the behavior of `s.replace({'a': None})` and `s.replace('a', None)` to understand the peculiarities of the `to_replace` parameter:

```
>>> s = pd.Series([10, 'a', 'a', 'b', 'a'])
```

When one uses a dict as the `to_replace` value, it is like the value(s) in the dict are equal to the `value` parameter. `s.replace({'a': None})` is equivalent to `s.replace(to_replace={'a': None}, value=None, method=None)`:

```
>>> s.replace({'a': None})
0      10
1     None
2     None
3       b
```

(continues on next page)

(continued from previous page)

```
4    None
dtype: object
```

When `value=None` and `to_replace` is a scalar, list or tuple, `replace` uses the method parameter (default ‘pad’) to do the replacement. So this is why the ‘a’ values are being replaced by 10 in rows 1 and 2 and ‘b’ in row 4 in this case. The command `s.replace('a', None)` is actually equivalent to `s.replace(to_replace='a', value=None, method='pad')`:

```
>>> s.replace('a', None)
0    10
1    10
2    10
3    b
4    b
dtype: object
```

pandas.Series.resample

`Series.resample(self, rule, axis=0, closed: Union[str, NoneType] = None, label: Union[str, NoneType] = None, convention: str = 'start', kind: Union[str, NoneType] = None, loffset=None, base: int = 0, on=None, level=None)`

Resample time-series data.

Convenience method for frequency conversion and resampling of time series. Object must have a datetime-like index (`DatetimeIndex`, `PeriodIndex`, or `TimedeltaIndex`), or pass datetime-like values to the `on` or `level` keyword.

Parameters

rule [DateOffset, Timedelta or str] The offset string or object representing target conversion.

axis [{0 or ‘index’, 1 or ‘columns’}, default 0] Which axis to use for up- or down-sampling. For `Series` this will default to 0, i.e. along the rows. Must be `DatetimeIndex`, `TimedeltaIndex` or `PeriodIndex`.

closed [{‘right’, ‘left’}, default None] Which side of bin interval is closed. The default is ‘left’ for all frequency offsets except for ‘M’, ‘A’, ‘Q’, ‘BM’, ‘BA’, ‘BQ’, and ‘W’ which all have a default of ‘right’.

label [{‘right’, ‘left’}, default None] Which bin edge label to label bucket with. The default is ‘left’ for all frequency offsets except for ‘M’, ‘A’, ‘Q’, ‘BM’, ‘BA’, ‘BQ’, and ‘W’ which all have a default of ‘right’.

convention [{‘start’, ‘end’, ‘s’, ‘e’}, default ‘start’] For `PeriodIndex` only, controls whether to use the start or end of `rule`.

kind [{‘timestamp’, ‘period’}, optional, default None] Pass ‘timestamp’ to convert the resulting index to a `DatetimeIndex` or ‘period’ to convert it to a `PeriodIndex`. By default the input representation is retained.

loffset [timedelta, default None] Adjust the resampled time labels.

base [int, default 0] For frequencies that evenly subdivide 1 day, the “origin” of the aggregated intervals. For example, for ‘5min’ frequency, base could range from 0 through 4. Defaults to 0.

on [str, optional] For a DataFrame, column to use instead of index for resampling. Column must be datetime-like.

level [str or int, optional] For a MultiIndex, level (name or number) to use for resampling. *level* must be datetime-like.

Returns

Resampler object

See also:

`groupby` Group by mapping, function, label, or list of labels.

`Series.resample` Resample a Series.

`DataFrame.resample` Resample a DataFrame.

Notes

See the [user guide](#) for more.

To learn more about the offset strings, please see [this link](#).

Examples

Start by creating a series with 9 one minute timestamps.

```
>>> index = pd.date_range('1/1/2000', periods=9, freq='T')
>>> series = pd.Series(range(9), index=index)
>>> series
2000-01-01 00:00:00    0
2000-01-01 00:01:00    1
2000-01-01 00:02:00    2
2000-01-01 00:03:00    3
2000-01-01 00:04:00    4
2000-01-01 00:05:00    5
2000-01-01 00:06:00    6
2000-01-01 00:07:00    7
2000-01-01 00:08:00    8
Freq: T, dtype: int64
```

Downsample the series into 3 minute bins and sum the values of the timestamps falling into a bin.

```
>>> series.resample('3T').sum()
2000-01-01 00:00:00     3
2000-01-01 00:03:00    12
2000-01-01 00:06:00    21
Freq: 3T, dtype: int64
```

Downsample the series into 3 minute bins as above, but label each bin using the right edge instead of the left. Please note that the value in the bucket used as the label is not included in the bucket, which it labels. For example, in the original series the bucket 2000-01-01 00:03:00 contains the value 3, but the summed value in the resampled bucket with the label 2000-01-01 00:03:00 does not include 3 (if it did, the summed value would be 6, not 3). To include this value close the right side of the bin interval as illustrated in the example below this one.

```
>>> series.resample('3T', label='right').sum()
2000-01-01 00:03:00    3
2000-01-01 00:06:00   12
2000-01-01 00:09:00   21
Freq: 3T, dtype: int64
```

Downsample the series into 3 minute bins as above, but close the right side of the bin interval.

```
>>> series.resample('3T', label='right', closed='right').sum()
2000-01-01 00:00:00    0
2000-01-01 00:03:00    6
2000-01-01 00:06:00   15
2000-01-01 00:09:00   15
Freq: 3T, dtype: int64
```

Upsample the series into 30 second bins.

```
>>> series.resample('30S').asfreq()[0:5]    # Select first 5 rows
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30    NaN
2000-01-01 00:01:00    1.0
2000-01-01 00:01:30    NaN
2000-01-01 00:02:00    2.0
Freq: 30S, dtype: float64
```

Upsample the series into 30 second bins and fill the NaN values using the `pad` method.

```
>>> series.resample('30S').pad()[0:5]
2000-01-01 00:00:00    0
2000-01-01 00:00:30    0
2000-01-01 00:01:00    1
2000-01-01 00:01:30    1
2000-01-01 00:02:00    2
Freq: 30S, dtype: int64
```

Upsample the series into 30 second bins and fill the NaN values using the `bfill` method.

```
>>> series.resample('30S').bfill()[0:5]
2000-01-01 00:00:00    0
2000-01-01 00:00:30    1
2000-01-01 00:01:00    1
2000-01-01 00:01:30    2
2000-01-01 00:02:00    2
Freq: 30S, dtype: int64
```

Pass a custom function via `apply`

```
>>> def custom_resampler(array_like):
...     return np.sum(array_like) + 5
...
>>> series.resample('3T').apply(custom_resampler)
2000-01-01 00:00:00    8
2000-01-01 00:03:00   17
2000-01-01 00:06:00   26
Freq: 3T, dtype: int64
```

For a Series with a PeriodIndex, the keyword `convention` can be used to control whether to use the start or end of *rule*.

Resample a year by quarter using ‘start’ *convention*. Values are assigned to the first quarter of the period.

```
>>> s = pd.Series([1, 2], index=pd.period_range('2012-01-01',
...                                         freq='A',
...                                         periods=2))
>>> s
2012    1
2013    2
Freq: A-DEC, dtype: int64
>>> s.resample('Q', convention='start').asfreq()
2012Q1    1.0
2012Q2    NaN
2012Q3    NaN
2012Q4    NaN
2013Q1    2.0
2013Q2    NaN
2013Q3    NaN
2013Q4    NaN
Freq: Q-DEC, dtype: float64
```

Resample quarters by month using ‘end’ *convention*. Values are assigned to the last month of the period.

```
>>> q = pd.Series([1, 2, 3, 4], index=pd.period_range('2018-01-01',
...                                         freq='Q',
...                                         periods=4))
>>> q
2018Q1    1
2018Q2    2
2018Q3    3
2018Q4    4
Freq: Q-DEC, dtype: int64
>>> q.resample('M', convention='end').asfreq()
2018-03    1.0
2018-04    NaN
2018-05    NaN
2018-06    2.0
2018-07    NaN
2018-08    NaN
2018-09    3.0
2018-10    NaN
2018-11    NaN
2018-12    4.0
Freq: M, dtype: float64
```

For DataFrame objects, the keyword *on* can be used to specify the column instead of the index for resampling.

```
>>> d = dict({'price': [10, 11, 9, 13, 14, 18, 17, 19],
...             'volume': [50, 60, 40, 100, 50, 100, 40, 50]})
>>> df = pd.DataFrame(d)
>>> df['week_starting'] = pd.date_range('01/01/2018',
...                                         periods=8,
...                                         freq='W')
>>> df
   price  volume week_starting
0      10      50  2018-01-07
1      11      60  2018-01-14
2       9      40  2018-01-21
```

(continues on next page)

(continued from previous page)

```

3      13     100    2018-01-28
4      14      50    2018-02-04
5      18     100    2018-02-11
6      17      40    2018-02-18
7      19      50    2018-02-25
>>> df.resample('M', on='week_starting').mean()
               price   volume
week_starting
2018-01-31      10.75     62.5
2018-02-28      17.00     60.0

```

For a DataFrame with MultiIndex, the keyword *level* can be used to specify on which level the resampling needs to take place.

```

>>> days = pd.date_range('1/1/2000', periods=4, freq='D')
>>> d2 = dict({'price': [10, 11, 9, 13, 14, 18, 17, 19],
...             'volume': [50, 60, 40, 100, 50, 100, 40, 50]})
>>> df2 = pd.DataFrame(d2,
...                      index=pd.MultiIndex.from_product([days,
...                                               ['morning',
...                                                'afternoon']]))

>>> df2
               price   volume
2000-01-01 morning      10      50
                  afternoon    11      60
2000-01-02 morning      9       40
                  afternoon    13     100
2000-01-03 morning     14       50
                  afternoon    18     100
2000-01-04 morning     17       40
                  afternoon    19      50
>>> df2.resample('D', level=0).sum()
               price   volume
2000-01-01      21     110
2000-01-02      22     140
2000-01-03      32     150
2000-01-04      36      90

```

pandas.Series.reset_index

`Series.reset_index(self, level=None, drop=False, name=None, inplace=False)`

Generate a new DataFrame or Series with the index reset.

This is useful when the index needs to be treated as a column, or when the index is meaningless and needs to be reset to the default before another operation.

Parameters

level [int, str, tuple, or list, default optional] For a Series with a MultiIndex, only remove the specified levels from the index. Removes all levels by default.

drop [bool, default False] Just reset the index, without inserting it as a column in the new DataFrame.

name [object, optional] The name to use for the column containing the original Series values. Uses `self.name` by default. This argument is ignored when `drop` is True.

`inplace` [bool, default False] Modify the Series in place (do not create a new object).

Returns

Series or DataFrame When `drop` is False (the default), a DataFrame is returned. The newly created columns will come first in the DataFrame, followed by the original Series values. When `drop` is True, a `Series` is returned. In either case, if `inplace=True`, no value is returned.

See also:

`DataFrame.reset_index` Analogous function for DataFrame.

Examples

```
>>> s = pd.Series([1, 2, 3, 4], name='foo',
...                 index=pd.Index(['a', 'b', 'c', 'd'], name='idx'))
```

Generate a DataFrame with default index.

```
>>> s.reset_index()
   idx    foo
0     a    1
1     b    2
2     c    3
3     d    4
```

To specify the name of the new column use `name`.

```
>>> s.reset_index(name='values')
   idx  values
0     a      1
1     b      2
2     c      3
3     d      4
```

To generate a new Series with the default set `drop` to True.

```
>>> s.reset_index(drop=True)
0     1
1     2
2     3
3     4
Name: foo, dtype: int64
```

To update the Series in place, without generating a new one set `inplace` to True. Note that it also requires `drop=True`.

```
>>> s.reset_index(inplace=True, drop=True)
>>> s
0     1
1     2
2     3
3     4
Name: foo, dtype: int64
```

The `level` parameter is interesting for Series with a multi-level index.

```
>>> arrays = [np.array(['bar', 'bar', 'baz', 'baz']),
...             np.array(['one', 'two', 'one', 'two'])]
>>> s2 = pd.Series(
...     range(4), name='foo',
...     index=pd.MultiIndex.from_arrays(arrays,
...                                     names=['a', 'b']))
```

To remove a specific level from the Index, use *level*.

```
>>> s2.reset_index(level='a')
      a    foo
b
one  bar    0
two  bar    1
one  baz    2
two  baz    3
```

If *level* is not set, all levels are removed from the Index.

```
>>> s2.reset_index()
      a    b    foo
0  bar  one    0
1  bar  two    1
2  baz  one    2
3  baz  two    3
```

pandas.Series.rfloordiv

`Series.rfloordiv(self, other, level=None, fill_value=None, axis=0)`

Return Integer division of series and other, element-wise (binary operator *rfloordiv*).

Equivalent to `other // series`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

Returns

Series The result of the operation.

See also:

`Series.floordiv`

Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.floordiv(b, fill_value=0)
a    1.0
b    NaN
c    NaN
d    0.0
e    NaN
dtype: float64
```

pandas.Series.rmod

`Series.rmod(self, other, level=None, fill_value=None, axis=0)`

Return Modulo of series and other, element-wise (binary operator *rmod*).

Equivalent to `other % series`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

Returns

Series The result of the operation.

See also:

`Series.mod`

Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.mod(b, fill_value=0)
a    0.0
b    NaN
c    NaN
d    0.0
e    NaN
dtype: float64
```

pandas.Series.rmul

`Series.rmul` (*self, other, level=None, fill_value=None, axis=0*)

Return Multiplication of series and other, element-wise (binary operator `rmul`).

Equivalent to `other * series`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

Returns

Series The result of the operation.

See also:

`Series.mul`

Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.multiply(b, fill_value=0)
a    1.0
b    0.0
c    0.0
d    0.0
e    NaN
dtype: float64
```

pandas.Series.rolling

`Series.rolling(self, window, min_periods=None, center=False, win_type=None, on=None, axis=0, closed=None)`

Provide rolling window calculations.

Parameters

window [int, offset, or BaseIndexer subclass] Size of the moving window. This is the number of observations used for calculating the statistic. Each window will be a fixed size.

If its an offset then this will be the time period of each window. Each window will be a variable sized based on the observations included in the time-period. This is only valid for datetimelike indexes.

If a BaseIndexer subclass is passed, calculates the window boundaries based on the defined `get_window_bounds` method. Additional rolling keyword arguments, namely `min_periods`, `center`, and `closed` will be passed to `get_window_bounds`.

min_periods [int, default None] Minimum number of observations in window required to have a value (otherwise result is NA). For a window that is specified by an offset, `min_periods` will default to 1. Otherwise, `min_periods` will default to the size of the window.

center [bool, default False] Set the labels at the center of the window.

win_type [str, default None] Provide a window type. If `None`, all points are evenly weighted. See the notes below for further information.

on [str, optional] For a DataFrame, a datetime-like column or MultiIndex level on which to calculate the rolling window, rather than the DataFrame's index. Provided integer column is ignored and excluded from result since an integer index is not used to calculate the rolling window.

axis [int or str, default 0]

closed [str, default None] Make the interval closed on the ‘right’, ‘left’, ‘both’ or ‘neither’ endpoints. For offset-based windows, it defaults to ‘right’. For fixed windows, defaults to ‘both’. Remaining cases not implemented for fixed windows.

Returns

a Window or Rolling sub-classed for the particular operation

See also:

[**expanding**](#) Provides expanding transformations.

[**ewm**](#) Provides exponential weighted functions.

Notes

By default, the result is set to the right edge of the window. This can be changed to the center of the window by setting `center=True`.

To learn more about the offsets & frequency strings, please see [this link](#).

The recognized win_types are:

- boxcar
- triang
- blackman
- hamming
- bartlett
- parzen
- bohman
- blackmanharris
- nuttall
- barthann
- kaiser (needs beta)
- gaussian (needs std)
- general_gaussian (needs power, width)
- slepian (needs width)
- exponential (needs tau), center is set to None.

If `win_type=None` all points are evenly weighted. To learn more about different window types see [scipy.signal window functions](#).

Examples

```
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})  
>>> df  
      B  
0   0.0  
1   1.0  
2   2.0  
3   NaN  
4   4.0
```

Rolling sum with a window length of 2, using the ‘triang’ window type.

```
>>> df.rolling(2, win_type='triang').sum()  
      B  
0   NaN  
1   0.5  
2   1.5  
3   NaN  
4   NaN
```

Rolling sum with a window length of 2, using the ‘gaussian’ window type (note how we need to specify std).

```
>>> df.rolling(2, win_type='gaussian').sum(std=3)  
      B  
0   NaN  
1   0.986207  
2   2.958621  
3   NaN  
4   NaN
```

Rolling sum with a window length of 2, min_periods defaults to the window length.

```
>>> df.rolling(2).sum()  
      B  
0   NaN  
1   1.0  
2   3.0  
3   NaN  
4   NaN
```

Same as above, but explicitly set the min_periods

```
>>> df.rolling(2, min_periods=1).sum()  
      B  
0   0.0  
1   1.0  
2   3.0  
3   2.0  
4   4.0
```

A ragged (meaning not-a-regular frequency), time-indexed DataFrame

```
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]},  
...                     index = [pd.Timestamp('20130101 09:00:00'),  
...                     pd.Timestamp('20130101 09:00:02')],  
...                     )
```

(continues on next page)

(continued from previous page)

```
... pd.Timestamp('20130101 09:00:03'),  
... pd.Timestamp('20130101 09:00:05'),  
... pd.Timestamp('20130101 09:00:06')])
```

```
>>> df  
          B  
2013-01-01 09:00:00  0.0  
2013-01-01 09:00:02  1.0  
2013-01-01 09:00:03  2.0  
2013-01-01 09:00:05  NaN  
2013-01-01 09:00:06  4.0
```

Contrasting to an integer rolling window, this will roll a variable length window corresponding to the time period. The default for min_periods is 1.

```
>>> df.rolling('2s').sum()  
          B  
2013-01-01 09:00:00  0.0  
2013-01-01 09:00:02  1.0  
2013-01-01 09:00:03  3.0  
2013-01-01 09:00:05  NaN  
2013-01-01 09:00:06  4.0
```

pandas.Series.round

`Series.round(self, decimals=0, *args, **kwargs)`

Round each value in a Series to the given number of decimals.

Parameters

decimals [int, default 0] Number of decimal places to round to. If decimals is negative, it specifies the number of positions to the left of the decimal point.

Returns

Series Rounded values of the Series.

See also:

[numpy.around](#) Round values of an np.array.

[DataFrame.round](#) Round values of a DataFrame.

Examples

```
>>> s = pd.Series([0.1, 1.3, 2.7])  
>>> s.round()  
0    0.0  
1    1.0  
2    3.0  
dtype: float64
```

pandas.Series.rpow

`Series.rpow(self, other, level=None, fill_value=None, axis=0)`

Return Exponential power of series and other, element-wise (binary operator *rpow*).

Equivalent to `other ** series`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

`other` [Series or scalar value]

`fill_value` [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

`level` [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

`Series` The result of the operation.

See also:

`Series.pow`

Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.pow(b, fill_value=0)
a    1.0
b    1.0
c    1.0
d    0.0
e    NaN
dtype: float64
```

pandas.Series.rsub

`Series.rsub(self, other, level=None, fill_value=None, axis=0)`

Return Subtraction of series and other, element-wise (binary operator `rsub`).

Equivalent to `other - series`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

`other` [Series or scalar value]

`fill_value` [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

`level` [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

`Series` The result of the operation.

See also:

`Series.sub`

Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.subtract(b, fill_value=0)
a    0.0
b    1.0
c    1.0
d   -1.0
e    NaN
dtype: float64
```

pandas.Series.rtruediv

`Series.rtruediv(self, other, level=None, fill_value=None, axis=0)`

Return Floating division of series and other, element-wise (binary operator `rtruediv`).

Equivalent to `other / series`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

`Series.truediv`

Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.divide(b, fill_value=0)
a    1.0
b    inf
c    inf
d    0.0
e    NaN
dtype: float64
```

pandas.Series.sample

`Series.sample(self: ~FrameOrSeries, n=None, frac=None, replace=False, weights=None, random_state=None, axis=None) → ~FrameOrSeries`
Return a random sample of items from an axis of object.

You can use `random_state` for reproducibility.

Parameters

`n` [int, optional] Number of items from axis to return. Cannot be used with `frac`. Default = 1 if `frac` = None.

`frac` [float, optional] Fraction of axis items to return. Cannot be used with `n`.

`replace` [bool, default False] Allow or disallow sampling of the same row more than once.

`weights` [str or ndarray-like, optional] Default ‘None’ results in equal probability weighting. If passed a Series, will align with target object on index. Index values in weights not found in sampled object will be ignored and index values in sampled object not in weights will be assigned weights of zero. If called on a DataFrame, will accept the name of a column when `axis` = 0. Unless weights are a Series, weights must be same length as axis being sampled. If weights do not sum to 1, they will be normalized to sum to 1. Missing values in the weights column will be treated as zero. Infinite values not allowed.

`random_state` [int or numpy.random.RandomState, optional] Seed for the random number generator (if int), or numpy RandomState object.

`axis` [{0 or ‘index’, 1 or ‘columns’, None}, default None] Axis to sample. Accepts axis number or name. Default is stat axis for given data type (0 for Series and DataFrames).

Returns

Series or DataFrame A new object of same type as caller containing `n` items randomly sampled from the caller object.

See also:

`numpy.random.choice` Generates a random sample from a given 1-D numpy array.

Notes

If `frac > 1`, `replacement` should be set to `True`.

Examples

```
>>> df = pd.DataFrame({'num_legs': [2, 4, 8, 0],
...                     'num_wings': [2, 0, 0, 0],
...                     'num_specimen_seen': [10, 2, 1, 8]},
...                     index=['falcon', 'dog', 'spider', 'fish'])
>>> df
   num_legs  num_wings  num_specimen_seen
falcon        2          2                  10
dog           4          0                   2
spider        8          0                   1
fish          0          0                   8
```

Extract 3 random elements from the Series `df['num_legs']`: Note that we use `random_state` to ensure the reproducibility of the examples.

```
>>> df['num_legs'].sample(n=3, random_state=1)
fish      0
spider    8
falcon    2
Name: num_legs, dtype: int64
```

A random 50% sample of the DataFrame with replacement:

```
>>> df.sample(frac=0.5, replace=True, random_state=1)
   num_legs  num_wings  num_specimen_seen
dog          4          0                  2
fish         0          0                  8
```

An upsample sample of the DataFrame with replacement: Note that `replace` parameter has to be `True` for `frac` parameter > 1 .

```
>>> df.sample(frac=2, replace=True, random_state=1)
   num_legs  num_wings  num_specimen_seen
dog          4          0                  2
fish         0          0                  8
falcon       2          2                 10
falcon       2          2                 10
fish         0          0                  8
dog          4          0                  2
fish         0          0                  8
dog          4          0                  2
```

Using a DataFrame column as weights. Rows with larger value in the `num_specimen_seen` column are more likely to be sampled.

```
>>> df.sample(n=2, weights='num_specimen_seen', random_state=1)
   num_legs  num_wings  num_specimen_seen
falcon       2          2                 10
fish         0          0                  8
```

pandas.Series.searchsorted

`Series.searchsorted(self, value, side='left', sorter=None)`

Find indices where elements should be inserted to maintain order.

Find the indices into a sorted Series `self` such that, if the corresponding elements in `value` were inserted before the indices, the order of `self` would be preserved.

Note: The Series *must* be monotonically sorted, otherwise wrong locations will likely be returned. Pandas does *not* check this for you.

Parameters

`value` [array_like] Values to insert into `self`.

`side` [{‘left’, ‘right’}, optional] If ‘left’, the index of the first suitable location found is given. If ‘right’, return the last such index. If there is no suitable index, return either

0 or N (where N is the length of *self*).

sorter [1-D array_like, optional] Optional array of integer indices that sort *self* into ascending order. They are typically the result of np.argsort.

Returns

int or array of int A scalar or array of insertion points with the same shape as *value*.

Changed in version 0.24.0: If *value* is a scalar, an int is now always returned. Previously, scalar inputs returned an 1-item array for *Series* and *Categorical*.

See also:

[sort_values](#)

[numpy.searchsorted](#)

Notes

Binary search is used to find the required insertion points.

Examples

```
>>> x = pd.Series([1, 2, 3])
>>> x
0    1
1    2
2    3
dtype: int64
```

```
>>> x.searchsorted(4)
3
```

```
>>> x.searchsorted([0, 4])
array([0, 3])
```

```
>>> x.searchsorted([1, 3], side='left')
array([0, 2])
```

```
>>> x.searchsorted([1, 3], side='right')
array([1, 3])
```

```
>>> x = pd.Categorical(['apple', 'bread', 'bread',
                           'cheese', 'milk'], ordered=True)
[apple, bread, bread, cheese, milk]
Categories (4, object): [apple < bread < cheese < milk]
```

```
>>> x.searchsorted('bread')
1
```

```
>>> x.searchsorted(['bread'], side='right')
array([3])
```

If the values are not monotonically sorted, wrong locations may be returned:

```
>>> x = pd.Series([2, 1, 3])
>>> x.searchsorted(1)
0 # wrong result, correct would be 1
```

pandas.Series.sem

`Series.sem(self, axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs)`

Return unbiased standard error of the mean over requested axis.

Normalized by N-1 by default. This can be changed using the ddof argument

Parameters

axis [{index (0)}]

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is $N - ddof$, where N represents the number of elements.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns

scalar or Series (if level specified)

pandas.Series.set_axis

`Series.set_axis(self, labels, axis=0, inplace=False)`

Assign desired index to given axis.

Indexes for column or row labels can be changed by assigning a list-like or Index.

Changed in version 0.21.0: The signature is now *labels* and *axis*, consistent with the rest of pandas API. Previously, the *axis* and *labels* arguments were respectively the first and second positional arguments.

Parameters

labels [list-like, Index] The values for the new index.

axis [{0 or ‘index’, 1 or ‘columns’}, default 0] The axis to update. The value 0 identifies the rows, and 1 identifies the columns.

inplace [bool, default False] Whether to return a new %(klass)s instance.

Returns

renamed [%(klass)s or None] An object of same type as caller if *inplace=False*, None otherwise.

See also:

`DataFrame.rename_axis` Alter the name of the index or columns.

Examples

Series

```
>>> s = pd.Series([1, 2, 3])
>>> s
0    1
1    2
2    3
dtype: int64
```

```
>>> s.set_axis(['a', 'b', 'c'], axis=0)
a    1
b    2
c    3
dtype: int64
```

DataFrame

```
>>> df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6]})
```

Change the row labels.

```
>>> df.set_axis(['a', 'b', 'c'], axis='index')
      A    B
a    1    4
b    2    5
c    3    6
```

Change the column labels.

```
>>> df.set_axis(['I', 'II'], axis='columns')
      I    II
0    1    4
1    2    5
2    3    6
```

Now, update the labels inplace.

```
>>> df.set_axis(['i', 'ii'], axis='columns', inplace=True)
>>> df
      i    ii
0    1    4
1    2    5
2    3    6
```

pandas.Series.shift

`Series.shift(self, periods=1, freq=None, axis=0, fill_value=None)`
Shift index by desired number of periods with an optional time `freq`.

When `freq` is not passed, shift the index without realigning the data. If `freq` is passed (in this case, the index must be date or datetime, or it will raise a `NotImplementedError`), the index will be increased using the periods and the `freq`.

Parameters

periods [int] Number of periods to shift. Can be positive or negative.

freq [DateOffset, tseries.offsets, timedelta, or str, optional] Offset to use from the tseries module or time rule (e.g. ‘EOM’). If *freq* is specified then the index values are shifted but the data is not realigned. That is, use *freq* if you would like to extend the index when shifting and preserve the original data.

axis [{0 or ‘index’, 1 or ‘columns’, None}, default None] Shift direction.

fill_value [object, optional] The scalar value to use for newly introduced missing values. the default depends on the dtype of *self*. For numeric data, np.nan is used. For datetime, timedelta, or period data, etc. NaT is used. For extension dtypes, *self.dtype*.na_value is used.

Changed in version 0.24.0.

Returns

Series Copy of input object, shifted.

See also:

[**Index.shift**](#) Shift values of Index.

[**DatetimeIndex.shift**](#) Shift values of DatetimeIndex.

[**PeriodIndex.shift**](#) Shift values of PeriodIndex.

[**tshift**](#) Shift the time index, using the index’s frequency if available.

Examples

```
>>> df = pd.DataFrame({'Col1': [10, 20, 15, 30, 45],
...                      'Col2': [13, 23, 18, 33, 48],
...                      'Col3': [17, 27, 22, 37, 52]})
```

```
>>> df.shift(periods=3)
   Col1  Col2  Col3
0    NaN    NaN    NaN
1    NaN    NaN    NaN
2    NaN    NaN    NaN
3   10.0   13.0   17.0
4   20.0   23.0   27.0
```

```
>>> df.shift(periods=1, axis='columns')
   Col1  Col2  Col3
0   10.0  13.0
1   20.0  23.0
2   15.0  18.0
3   30.0  33.0
4   45.0  48.0
```

```
>>> df.shift(periods=3, fill_value=0)
   Col1  Col2  Col3
0     0     0     0
1     0     0     0
2     0     0     0
3    10    13    17
4    20    23    27
```

pandas.Series.skew

`Series.skew(self, axis=None, skipna=None, level=None, numeric_only=None, **kwargs)`

Return unbiased skew over requested axis.

Normalized by N-1.

Parameters

axis [{index (0)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

****kwargs** Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)

pandas.Series.slice_shift

`Series.slice_shift(self: ~FrameOrSeries, periods: int = 1, axis=0) → ~FrameOrSeries`

Equivalent to `shift` without copying data.

The shifted data will not include the dropped periods and the shifted axis will be smaller than the original.

Parameters

periods [int] Number of periods to move, can be positive or negative.

Returns

shifted [same type as caller]

Notes

While the `slice_shift` is faster than `shift`, you may pay for it later during alignment.

pandas.Series.sort_index

`Series.sort_index(self, axis=0, level=None, ascending=True, inplace=False, kind='quicksort', na_position='last', sort_remaining=True, ignore_index: bool = False)`

Sort Series by index labels.

Returns a new Series sorted by label if `inplace` argument is `False`, otherwise updates the original series and returns None.

Parameters

axis [int, default 0] Axis to direct sorting. This can only be 0 for Series.

level [int, optional] If not None, sort on values in specified index level(s).

ascending [bool, default true] Sort ascending vs. descending.

inplace [bool, default False] If True, perform operation in-place.

kind [{‘quicksort’, ‘mergesort’, ‘heapsort’}, default ‘quicksort’] Choice of sorting algorithm. See also `numpy.sort()` for more information. ‘mergesort’ is the only stable algorithm. For DataFrames, this option is only applied when sorting on a single column or label.

na_position [{‘first’, ‘last’}, default ‘last’] If ‘first’ puts NaNs at the beginning, ‘last’ puts NaNs at the end. Not implemented for MultiIndex.

sort_remaining [bool, default True] If True and sorting by level and index is multilevel, sort by other levels too (in order) after sorting by specified level.

ignore_index [bool, default False] If True, the resulting axis will be labeled 0, 1, …, n - 1.

New in version 1.0.0.

Returns

Series The original Series sorted by the labels.

See also:

`DataFrame.sort_index` Sort DataFrame by the index.

`DataFrame.sort_values` Sort DataFrame by the value.

`Series.sort_values` Sort Series by the value.

Examples

```
>>> s = pd.Series(['a', 'b', 'c', 'd'], index=[3, 2, 1, 4])
>>> s.sort_index()
1    c
2    b
3    a
4    d
dtype: object
```

Sort Descending

```
>>> s.sort_index(ascending=False)
4    d
3    a
2    b
1    c
dtype: object
```

Sort Inplace

```
>>> s.sort_index(inplace=True)
>>> s
1    c
2    b
3    a
4    d
dtype: object
```

By default NaNs are put at the end, but use `na_position` to place them at the beginning

```
>>> s = pd.Series(['a', 'b', 'c', 'd'], index=[3, 2, 1, np.nan])
>>> s.sort_index(na_position='first')
NaN      d
1.0      c
2.0      b
3.0      a
dtype: object
```

Specify index level to sort

```
>>> arrays = [np.array(['qux', 'qux', 'foo', 'foo',
...                     'baz', 'baz', 'bar', 'bar']),
...            np.array(['two', 'one', 'two', 'one',
...                     'two', 'one', 'two', 'one'])]
>>> s = pd.Series([1, 2, 3, 4, 5, 6, 7, 8], index=arrays)
>>> s.sort_index(level=1)
bar  one    8
baz  one    6
foo  one    4
qux  one    2
bar  two    7
baz  two    5
foo  two    3
qux  two    1
dtype: int64
```

Does not sort by remaining levels when sorting by levels

```
>>> s.sort_index(level=1, sort_remaining=False)
qux  one    2
foo  one    4
baz  one    6
bar  one    8
qux  two    1
foo  two    3
baz  two    5
bar  two    7
dtype: int64
```

pandas.Series.sort_values

`Series.sort_values(self, axis=0, ascending=True, inplace=False, kind='quicksort', na_position='last', ignore_index=False)`

Sort by the values.

Sort a Series in ascending or descending order by some criterion.

Parameters

axis [{0 or ‘index’}, default 0] Axis to direct sorting. The value ‘index’ is accepted for compatibility with DataFrame.sort_values.

ascending [bool, default True] If True, sort values in ascending order, otherwise descending.

inplace [bool, default False] If True, perform operation in-place.

kind [{‘quicksort’, ‘mergesort’ or ‘heapsort’}], default ‘quicksort’] Choice of sorting algorithm. See also `numpy.sort()` for more information. ‘mergesort’ is the only stable algorithm.

na_position [{‘first’ or ‘last’}], default ‘last’] Argument ‘first’ puts NaNs at the beginning, ‘last’ puts NaNs at the end.

ignore_index [bool, default False] If True, the resulting axis will be labeled 0, 1, …, n - 1.

New in version 1.0.0.

Returns

Series Series ordered by values.

See also:

`Series.sort_index` Sort by the Series indices.

`DataFrame.sort_values` Sort DataFrame by the values along either axis.

`DataFrame.sort_index` Sort DataFrame by indices.

Examples

```
>>> s = pd.Series([np.nan, 1, 3, 10, 5])
>>> s
0      NaN
1      1.0
2      3.0
3     10.0
4      5.0
dtype: float64
```

Sort values ascending order (default behaviour)

```
>>> s.sort_values(ascending=True)
1      1.0
2      3.0
4      5.0
3     10.0
0      NaN
dtype: float64
```

Sort values descending order

```
>>> s.sort_values(ascending=False)
3     10.0
4      5.0
2      3.0
1      1.0
0      NaN
dtype: float64
```

Sort values inplace

```
>>> s.sort_values(ascending=False, inplace=True)
>>> s
3      10.0
4      5.0
2      3.0
1      1.0
0      NaN
dtype: float64
```

Sort values putting NAs first

```
>>> s.sort_values(na_position='first')
0      NaN
1      1.0
2      3.0
4      5.0
3     10.0
dtype: float64
```

Sort a series of strings

```
>>> s = pd.Series(['z', 'b', 'd', 'a', 'c'])
>>> s
0    z
1    b
2    d
3    a
4    c
dtype: object
```

```
>>> s.sort_values()
3    a
1    b
4    c
2    d
0    z
dtype: object
```

pandas.Series.sparse

`Series.sparse()`

Accessor for SparseSparse from other sparse matrix data types.

pandas.Series.squeeze

`Series.squeeze(self, axis=None)`

Squeeze 1 dimensional axis objects into scalars.

Series or DataFrames with a single element are squeezed to a scalar. DataFrames with a single column or a single row are squeezed to a Series. Otherwise the object is unchanged.

This method is most useful when you don't know if your object is a Series or DataFrame, but you do know it has just a single column. In that case you can safely call `squeeze` to ensure you have a Series.

Parameters

axis [{0 or ‘index’, 1 or ‘columns’, None}, default None] A specific axis to squeeze. By default, all length-1 axes are squeezed.

Returns

DataFrame, Series, or scalar The projection after squeezing *axis* or all the axes.

See also:

Series.iloc Integer-location based indexing for selecting scalars.

DataFrame.iloc Integer-location based indexing for selecting Series.

Series.to_frame Inverse of DataFrame.squeeze for a single-column DataFrame.

Examples

```
>>> primes = pd.Series([2, 3, 5, 7])
```

Slicing might produce a Series with a single value:

```
>>> even_primes = primes[primes % 2 == 0]
>>> even_primes
0    2
dtype: int64
```

```
>>> even_primes.squeeze()
2
```

Squeezing objects with more than one value in every axis does nothing:

```
>>> odd_primes = primes[primes % 2 == 1]
>>> odd_primes
1    3
2    5
3    7
dtype: int64
```

```
>>> odd_primes.squeeze()
1    3
2    5
3    7
dtype: int64
```

Squeezing is even more effective when used with DataFrames.

```
>>> df = pd.DataFrame([[1, 2], [3, 4]], columns=['a', 'b'])
>>> df
   a   b
0  1  2
1  3  4
```

Slicing a single column will produce a DataFrame with the columns having only one value:

```
>>> df_a = df[['a']]
>>> df_a
a
```

(continues on next page)

(continued from previous page)

0	1
1	3

So the columns can be squeezed down, resulting in a Series:

```
>>> df_a.squeeze('columns')
0    1
1    3
Name: a, dtype: int64
```

Slicing a single row from a single column will produce a single scalar DataFrame:

```
>>> df_0a = df.loc[df.index < 1, ['a']]
>>> df_0a
   a
0  1
```

Squeezing the rows produces a single scalar Series:

```
>>> df_0a.squeeze('rows')
a    1
Name: 0, dtype: int64
```

Squeezing all axes will project directly into a scalar:

```
>>> df_0a.squeeze()
1
```

pandas.Series.std

`Series.std(self, axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs)`
Return sample standard deviation over requested axis.

Normalized by N-1 by default. This can be changed using the ddof argument

Parameters

`axis` [{index (0)}]

`skipna` [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

`level` [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

`ddof` [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.

`numeric_only` [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns

`scalar or Series (if level specified)`

pandas.Series.str

`Series.str()`

Vectorized string functions for Series and Index. NAs stay NA unless handled otherwise by a particular method. Patterned after Python's string methods, with some inspiration from R's stringr package.

Examples

```
>>> s.str.split('_')
>>> s.str.replace('_', '')
```

pandas.Series.sub

`Series.sub(self, other, level=None, fill_value=None, axis=0)`

Return Subtraction of series and other, element-wise (binary operator *sub*).

Equivalent to `series - other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

`other` [Series or scalar value]

`fill_value` [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

`level` [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

Returns

`Series` The result of the operation.

See also:

`Series.rsub`

Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
```

(continues on next page)

(continued from previous page)

```
>>> a.subtract(b, fill_value=0)
a    0.0
b    1.0
c    1.0
d   -1.0
e    NaN
dtype: float64
```

pandas.Series.subtract

`Series.subtract(self, other, level=None, fill_value=None, axis=0)`

Return Subtraction of series and other, element-wise (binary operator `sub`).

Equivalent to `series - other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

`Series.rsub`

Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.subtract(b, fill_value=0)
a    0.0
b    1.0
```

(continues on next page)

(continued from previous page)

```
c    1.0
d   -1.0
e    NaN
dtype: float64
```

pandas.Series.sum

`Series.sum(self, axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs)`

Return the sum of the values for the requested axis.

This is equivalent to the method `numpy.sum`.

Parameters

`axis` [{index (0)}] Axis for the function to be applied on.

`skipna` [bool, default True] Exclude NA/null values when computing the result.

`level` [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

`numeric_only` [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

`min_count` [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

New in version 0.22.0: Added with the default being 0. This means the sum of an all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.

`**kwargs` Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)

See also:

`Series.sum` Return the sum.

`Series.min` Return the minimum.

`Series.max` Return the maximum.

`Series.idxmin` Return the index of the minimum.

`Series.idxmax` Return the index of the maximum.

`DataFrame.sum` Return the sum over the requested axis.

`DataFrame.min` Return the minimum over the requested axis.

`DataFrame.max` Return the maximum over the requested axis.

`DataFrame.idxmin` Return the index of the minimum over the requested axis.

`DataFrame.idxmax` Return the index of the maximum over the requested axis.

Examples

```
>>> idx = pd.MultiIndex.from_arrays([
...     ['warm', 'warm', 'cold', 'cold'],
...     ['dog', 'falcon', 'fish', 'spider']],
...     names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded    animal
warm        dog        4
            falcon     2
cold        fish       0
            spider     8
Name: legs, dtype: int64
```

```
>>> s.sum()
14
```

Sum using level names, as well as indices.

```
>>> s.sum(level='blooded')
blooded
warm      6
cold      8
Name: legs, dtype: int64
```

```
>>> s.sum(level=0)
blooded
warm      6
cold      8
Name: legs, dtype: int64
```

By default, the sum of an empty or all-NA Series is 0.

```
>>> pd.Series([]).sum()  # min_count=0 is the default
0.0
```

This can be controlled with the `min_count` parameter. For example, if you'd like the sum of an empty series to be NaN, pass `min_count=1`.

```
>>> pd.Series([]).sum(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```
>>> pd.Series([np.nan]).sum()
0.0
```

```
>>> pd.Series([np.nan]).sum(min_count=1)
nan
```

pandas.Series.swapaxes

`Series.swapaxes(self: ~FrameOrSeries, axis1, axis2, copy=True) → ~FrameOrSeries`
 Interchange axes and swap values axes appropriately.

Returns

`y` [same as input]

pandas.Series.swaplevel

`Series.swaplevel(self, i=-2, j=-1, copy=True)`
 Swap levels `i` and `j` in a `MultiIndex`.

Default is to swap the two innermost levels of the index.

Parameters

`i, j` [int, str] Level of the indices to be swapped. Can pass level name as string.
`copy` [bool, default True] Whether to copy underlying data.

Returns

`Series` Series with levels swapped in MultiIndex.

pandas.Series.tail

`Series.tail(self: ~FrameOrSeries, n: int = 5) → ~FrameOrSeries`
 Return the last `n` rows.

This function returns last `n` rows from the object based on position. It is useful for quickly verifying data, for example, after sorting or appending rows.

For negative values of `n`, this function returns all rows except the first `n` rows, equivalent to `df[n:]`.

Parameters

`n` [int, default 5] Number of rows to select.

Returns

type of caller The last `n` rows of the caller object.

See also:

`DataFrame.head` The first `n` rows of the caller object.

Examples

```
>>> df = pd.DataFrame({'animal': ['alligator', 'bee', 'falcon', 'lion',
...                               'monkey', 'parrot', 'shark', 'whale', 'zebra']})
>>> df
      animal
0  alligator
1        bee
2      falcon
3        lion
```

(continues on next page)

(continued from previous page)

```
4     monkey
5     parrot
6     shark
7     whale
8     zebra
```

Viewing the last 5 lines

```
>>> df.tail()
      animal
4    monkey
5   parrot
6   shark
7   whale
8   zebra
```

Viewing the last n lines (three in this case)

```
>>> df.tail(3)
      animal
6   shark
7   whale
8   zebra
```

For negative values of n

```
>>> df.tail(-3)
      animal
3   lion
4   monkey
5   parrot
6   shark
7   whale
8   zebra
```

pandas.Series.take

`Series.take(self, indices, axis=0, is_copy=None, **kwargs) → 'Series'`

Return the elements in the given *positional* indices along an axis.

This means that we are not indexing according to actual values in the index attribute of the object. We are indexing according to the actual position of the element in the object.

Parameters

indices [array-like] An array of ints indicating which positions to take.

axis [{0 or ‘index’, 1 or ‘columns’, None}, default 0] The axis on which to select elements. 0 means that we are selecting rows, 1 means that we are selecting columns.

is_copy [bool] Before pandas 1.0, `is_copy=False` can be specified to ensure that the return value is an actual copy. Starting with pandas 1.0, `take` always returns a copy, and the keyword is therefore deprecated.

Deprecated since version 1.0.0.

****kwargs** For compatibility with `numpy.take()`. Has no effect on the output.

Returns

taken [same type as caller] An array-like containing the elements taken from the object.

See also:

[**DataFrame.loc**](#) Select a subset of a DataFrame by labels.

[**DataFrame.iloc**](#) Select a subset of a DataFrame by positions.

[**numpy.take**](#) Take elements from an array along an axis.

Examples

```
>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
...                     ('parrot', 'bird', 24.0),
...                     ('lion', 'mammal', 80.5),
...                     ('monkey', 'mammal', np.nan)],
...                     columns=['name', 'class', 'max_speed'],
...                     index=[0, 2, 3, 1])
>>> df
   name    class  max_speed
0  falcon     bird      389.0
2  parrot     bird       24.0
3    lion  mammal       80.5
1  monkey  mammal        NaN
```

Take elements at positions 0 and 3 along the axis 0 (default).

Note how the actual indices selected (0 and 1) do not correspond to our selected indices 0 and 3. That's because we are selecting the 0th and 3rd rows, not rows whose indices equal 0 and 3.

```
>>> df.take([0, 3])
   name    class  max_speed
0  falcon     bird      389.0
1  monkey  mammal        NaN
```

Take elements at indices 1 and 2 along the axis 1 (column selection).

```
>>> df.take([1, 2], axis=1)
      class  max_speed
0    bird      389.0
2    bird       24.0
3  mammal       80.5
1  mammal        NaN
```

We may take elements using negative integers for positive indices, starting from the end of the object, just like with Python lists.

```
>>> df.take([-1, -2])
      name    class  max_speed
1  monkey  mammal        NaN
3    lion  mammal       80.5
```

`pandas.Series.to_clipboard`

`Series.to_clipboard(self, excel: bool = True, sep: Union[str, NoneType] = None, **kwargs) → None`
Copy object to the system clipboard.

Write a text representation of object to the system clipboard. This can be pasted into Excel, for example.

Parameters

`excel` [bool, default True] Produce output in a csv format for easy pasting into excel.

- True, use the provided separator for csv pasting.
- False, write a string representation of the object to the clipboard.

`sep` [str, default '\t'] Field delimiter.

`**kwargs` These parameters will be passed to DataFrame.to_csv.

See also:

`DataFrame.to_csv` Write a DataFrame to a comma-separated values (csv) file.

`read_clipboard` Read text from clipboard and pass to read_table.

Notes

Requirements for your platform.

- Linux : `xclip`, or `xsel` (with `PyQt4` modules)
- Windows : none
- OS X : none

Examples

Copy the contents of a DataFrame to the clipboard.

```
>>> df = pd.DataFrame([[1, 2, 3], [4, 5, 6]], columns=['A', 'B', 'C'])
>>> df.to_clipboard(sep=',')
... # Wrote the following to the system clipboard:
... # ,A,B,C
... # 0,1,2,3
... # 1,4,5,6
```

We can omit the the index by passing the keyword `index` and setting it to false.

```
>>> df.to_clipboard(sep=',', index=False)
... # Wrote the following to the system clipboard:
... # A,B,C
... # 1,2,3
... # 4,5,6
```

pandas.Series.to_csv

```
Series.to_csv(self, path_or_buf: Union[str, pathlib.Path, IO[~AnyStr], NoneType] = None,
              sep: str = ',', na_rep: str = "", float_format: Union[str, NoneType] = None,
              columns: Union[Sequence[Union[Hashable, NoneType]], NoneType] = None,
              header: Union[bool, List[str]] = True, index: bool = True, index_label:
              Union[bool, str, Sequence[Union[Hashable, NoneType]], NoneType] = None, mode:
              str = 'w', encoding: Union[str, NoneType] = None, compression: Union[str,
              Mapping[str, str], NoneType] = 'infer', quoting: Union[int, NoneType] = None,
              quotechar: str = "", line_terminator: Union[str, NoneType] = None, chunksize:
              Union[int, NoneType] = None, date_format: Union[str, NoneType] = None, double-
              quote: bool = True, escapechar: Union[str, NoneType] = None, decimal: Union[str,
              NoneType] = '.') → Union[str, NoneType]
```

Write object to a comma-separated values (csv) file.

Changed in version 0.24.0: The order of arguments for Series was changed.

Parameters

path_or_buf [str or file handle, default None] File path or object, if None is provided the result is returned as a string. If a file object is passed it should be opened with `newline=`, disabling universal newlines.

Changed in version 0.24.0: Was previously named “path” for Series.

sep [str, default ‘,’] String of length 1. Field delimiter for the output file.

na_rep [str, default ‘’] Missing data representation.

float_format [str, default None] Format string for floating point numbers.

columns [sequence, optional] Columns to write.

header [bool or list of str, default True] Write out the column names. If a list of strings is given it is assumed to be aliases for the column names.

Changed in version 0.24.0: Previously defaulted to False for Series.

index [bool, default True] Write row names (index).

index_label [str or sequence, or False, default None] Column label for index column(s) if desired. If None is given, and `header` and `index` are True, then the index names are used. A sequence should be given if the object uses MultiIndex. If False do not print fields for index names. Use `index_label=False` for easier importing in R.

mode [str] Python write mode, default ‘w’.

encoding [str, optional] A string representing the encoding to use in the output file, defaults to ‘utf-8’.

compression [str or dict, default ‘infer’] If str, represents compression mode. If dict, value at ‘method’ is the compression mode. Compression mode may be any of the following possible values: {‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}. If compression mode is ‘infer’ and `path_or_buf` is path-like, then detect compression mode from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’ or ‘.xz’. (otherwise no compression). If dict given and mode is ‘zip’ or inferred as ‘zip’, other entries passed as additional compression options.

Changed in version 1.0.0: May now be a dict with key ‘method’ as compression mode and other entries as additional compression options if compression mode is ‘zip’.

quoting [optional constant from csv module] Defaults to csv.QUOTE_MINIMAL.
If you have set a *float_format* then floats are converted to strings and thus
csv.QUOTE_NONNUMERIC will treat them as non-numeric.

quotechar [str, default ""] String of length 1. Character used to quote fields.

line_terminator [str, optional] The newline character or character sequence to use in the
output file. Defaults to *os.linesep*, which depends on the OS in which this method is
called ('n' for linux, 'rn' for Windows, i.e.).

Changed in version 0.24.0.

chunksize [int or None] Rows to write at a time.

date_format [str, default None] Format string for datetime objects.

doublequote [bool, default True] Control quoting of *quotechar* inside a field.

escapechar [str, default None] String of length 1. Character used to escape *sep* and
quotechar when appropriate.

decimal [str, default '.'] Character recognized as decimal separator. E.g. use ',' for
European data.

Returns

None or str If path_or_buf is None, returns the resulting csv format as a string. Otherwise returns None.

See also:

[**read_csv**](#) Load a CSV file into a DataFrame.

[**to_excel**](#) Write DataFrame to an Excel file.

Examples

```
>>> df = pd.DataFrame({'name': ['Raphael', 'Donatello'],
...                     'mask': ['red', 'purple'],
...                     'weapon': ['sai', 'bo staff']})
>>> df.to_csv(index=False)
'name,mask,weapon\nRaphael,red,sai\nDonatello,purple,bo staff\n'
```

Create 'out.zip' containing 'out.csv'

```
>>> compression_opts = dict(method='zip',
...                           archive_name='out.csv')
>>> df.to_csv('out.zip', index=False,
...            compression=compression_opts)
```

pandas.Series.to_dict

`Series.to_dict(self, into=<class 'dict'>)`

Convert Series to {label -> value} dict or dict-like object.

Parameters

`into` [class, default dict] The collections.abc.Mapping subclass to use as the return object.

Can be the actual class or an empty instance of the mapping type you want. If you want a collections.defaultdict, you must pass it initialized.

New in version 0.21.0.

Returns

`collections.abc.Mapping` Key-value representation of Series.

Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s.to_dict()
{0: 1, 1: 2, 2: 3, 3: 4}
>>> from collections import OrderedDict, defaultdict
>>> s.to_dict(OrderedDict)
OrderedDict([(0, 1), (1, 2), (2, 3), (3, 4)])
>>> dd = defaultdict(list)
>>> s.to_dict(dd)
defaultdict(<class 'list'>, {0: 1, 1: 2, 2: 3, 3: 4})
```

pandas.Series.to_excel

`Series.to_excel(self, excel_writer, sheet_name='Sheet1', na_rep='', float_format=None, columns=None, header=True, index=True, index_label=None, startrow=0, startcol=0, engine=None, merge_cells=True, encoding=None, inf_rep='inf', verbose=True, freeze_panes=None) → None`

Write object to an Excel sheet.

To write a single object to an Excel .xlsx file it is only necessary to specify a target file name. To write to multiple sheets it is necessary to create an *ExcelWriter* object with a target file name, and specify a sheet in the file to write to.

Multiple sheets may be written to by specifying unique *sheet_name*. With all data written to the file it is necessary to save the changes. Note that creating an *ExcelWriter* object with a file name that already exists will result in the contents of the existing file being erased.

Parameters

`excel_writer` [str or ExcelWriter object] File path or existing ExcelWriter.

`sheet_name` [str, default ‘Sheet1’] Name of sheet which will contain DataFrame.

`na_rep` [str, default ‘’] Missing data representation.

`float_format` [str, optional] Format string for floating point numbers. For example `float_format=".2f"` will format 0.1234 to 0.12.

`columns` [sequence or list of str, optional] Columns to write.

header [bool or list of str, default True] Write out the column names. If a list of string is given it is assumed to be aliases for the column names.

index [bool, default True] Write row names (index).

index_label [str or sequence, optional] Column label for index column(s) if desired. If not specified, and *header* and *index* are True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.

startrow [int, default 0] Upper left cell row to dump data frame.

startcol [int, default 0] Upper left cell column to dump data frame.

engine [str, optional] Write engine to use, ‘openpyxl’ or ‘xlsxwriter’. You can also set this via the options `io.excel.xlsx.writer`, `io.excel.xls.writer`, and `io.excel.xlsb.writer`.

merge_cells [bool, default True] Write MultiIndex and Hierarchical Rows as merged cells.

encoding [str, optional] Encoding of the resulting excel file. Only necessary for xlwt, other writers support unicode natively.

inf_rep [str, default ‘inf’] Representation for infinity (there is no native representation for infinity in Excel).

verbose [bool, default True] Display more information in the error logs.

freeze_panes [tuple of int (length 2), optional] Specifies the one-based bottommost row and rightmost column that is to be frozen.

See also:

[`to_csv`](#) Write DataFrame to a comma-separated values (csv) file.

[`ExcelWriter`](#) Class for writing DataFrame objects into excel sheets.

[`read_excel`](#) Read an Excel file into a pandas DataFrame.

[`read_csv`](#) Read a comma-separated values (csv) file into DataFrame.

Notes

For compatibility with `to_csv()`, `to_excel` serializes lists and dicts to strings before writing.

Once a workbook has been saved it is not possible write further data without rewriting the whole workbook.

Examples

Create, write to and save a workbook:

```
>>> df1 = pd.DataFrame([['a', 'b'], ['c', 'd']],
...                      index=['row 1', 'row 2'],
...                      columns=['col 1', 'col 2'])
>>> df1.to_excel("output.xlsx")
```

To specify the sheet name:

```
>>> df1.to_excel("output.xlsx",
...                 sheet_name='Sheet_name_1')
```

If you wish to write to more than one sheet in the workbook, it is necessary to specify an ExcelWriter object:

```
>>> df2 = df1.copy()
>>> with pd.ExcelWriter('output.xlsx') as writer:
...     df1.to_excel(writer, sheet_name='Sheet_name_1')
...     df2.to_excel(writer, sheet_name='Sheet_name_2')
```

ExcelWriter can also be used to append to an existing Excel file:

```
>>> with pd.ExcelWriter('output.xlsx',
...                      mode='a') as writer:
...     df.to_excel(writer, sheet_name='Sheet_name_3')
```

To set the library that is used to write the Excel file, you can pass the *engine* keyword (the default engine is automatically chosen depending on the file extension):

```
>>> df1.to_excel('output1.xlsx', engine='xlsxwriter')
```

pandas.Series.to_frame

`Series.to_frame(self, name=None)`

Convert Series to DataFrame.

Parameters

`name` [object, default None] The passed name should substitute for the series name (if it has one).

Returns

`DataFrame` DataFrame representation of Series.

Examples

```
>>> s = pd.Series(["a", "b", "c"],
...                 name="vals")
>>> s.to_frame()
   vals
0    a
1    b
2    c
```

pandas.Series.to_hdf

`Series.to_hdf(self, path_or_buf, key: str, mode: str = 'a', complevel: Union[int, NoneType] = None, complib: Union[str, NoneType] = None, append: bool = False, format: Union[str, NoneType] = None, index: bool = True, min_itemsize: Union[int, Dict[str, int], NoneType] = None, nan_rep=None, dropna: Union[bool, NoneType] = None, data_columns: Union[List[str], NoneType] = None, errors: str = 'strict', encoding: str = 'UTF-8') → None`

Write the contained data to an HDF5 file using HDFStore.

Hierarchical Data Format (HDF) is self-describing, allowing an application to interpret the structure and contents of a file with no outside information. One HDF file can hold a mix of related objects which can be accessed as a group or as individual objects.

In order to add another DataFrame or Series to an existing HDF file please use append mode and a different a key.

For more information see the [user guide](#).

Parameters

path_or_buf [str or pandas.HDFStore] File path or HDFStore object.

key [str] Identifier for the group in the store.

mode [{‘a’, ‘w’, ‘r+’}, default ‘a’] Mode to open file:

- ‘w’: write, a new file is created (an existing file with the same name would be deleted).
- ‘a’: append, an existing file is opened for reading and writing, and if the file does not exist it is created.
- ‘r+’: similar to ‘a’, but the file must already exist.

complevel [{0-9}, optional] Specifies a compression level for data. A value of 0 disables compression.

complib [{‘zlib’, ‘lzo’, ‘bzip2’, ‘blosc’}, default ‘zlib’] Specifies the compression library to be used. As of v0.20.2 these additional compressors for Blosc are supported (default if no compressor specified: ‘blosc:blosclz’): {‘blosc:blosclz’, ‘blosc:lz4’, ‘blosc:lz4hc’, ‘blosc:snappy’, ‘blosc:zlib’, ‘blosc:zstd’}. Specifying a compression library which is not available issues a ValueError.

append [bool, default False] For Table formats, append the input data to the existing.

format [{‘fixed’, ‘table’, None}, default ‘fixed’] Possible values:

- ‘fixed’: Fixed format. Fast writing/reading. Not-appendable, nor searchable.
- ‘table’: Table format. Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data.
- If None, pd.get_option(‘io.hdf.default_format’) is checked, followed by fallback to “fixed”

errors [str, default ‘strict’] Specifies how encoding and decoding errors are to be handled.

See the errors argument for [open\(\)](#) for a full list of options.

encoding [str, default “UTF-8”]

min_itemsize [dict or int, optional] Map column names to minimum string sizes for columns.

nan_rep [Any, optional] How to represent null values as str. Not allowed with append=True.

data_columns [list of columns or True, optional] List of columns to create as indexed data columns for on-disk queries, or True to use all columns. By default only the axes of the object are indexed. See [Query via data columns](#). Applicable only to format=’table’.

See also:

`DataFrame.read_hdf` Read from HDF file.

`DataFrame.to_parquet` Write a DataFrame to the binary parquet format.

`DataFrame.to_sql` Write to a sql table.

`DataFrame.to_feather` Write out feather-format for DataFrames.

`DataFrame.to_csv` Write out to a csv file.

Examples

```
>>> df = pd.DataFrame({'A': [1, 2, 3], 'B': [4, 5, 6]},  
...                 index=['a', 'b', 'c'])  
>>> df.to_hdf('data.h5', key='df', mode='w')
```

We can add another object to the same file:

```
>>> s = pd.Series([1, 2, 3, 4])  
>>> s.to_hdf('data.h5', key='s')
```

Reading from HDF file:

```
>>> pd.read_hdf('data.h5', 'df')  
A   B  
a   1   4  
b   2   5  
c   3   6  
>>> pd.read_hdf('data.h5', 's')  
0    1  
1    2  
2    3  
3    4  
dtype: int64
```

Deleting file with data:

```
>>> import os  
>>> os.remove('data.h5')
```

pandas.Series.to_json

`Series.to_json(self, path_or_buf: Union[str, pathlib.Path, IO[~AnyStr], NoneType] = None, orient: Union[str, NoneType] = None, date_format: Union[str, NoneType] = None, double_precision: int = 10, force_ascii: bool = True, date_unit: str = 'ms', default_handler: Union[Callable[[Any], Union[str, int, float, bool, List, Dict]], NoneType] = None, lines: bool = False, compression: Union[str, NoneType] = 'infer', index: bool = True, indent: Union[int, NoneType] = None) → Union[str, NoneType]`

Convert the object to a JSON string.

Note NaN's and None will be converted to null and datetime objects will be converted to UNIX timestamps.

Parameters

path_or_buf [str or file handle, optional] File path or object. If not specified, the result is returned as a string.

orient [str] Indication of expected JSON string format.

- Series:

- default is ‘index’
- allowed values are: {‘split’,‘records’,‘index’,‘table’}.

- DataFrame:

- default is ‘columns’
- allowed values are: {‘split’,‘records’,‘index’,‘columns’,‘values’,‘table’}.

- The format of the JSON string:

- ‘split’ : dict like {‘index’ -> [index], ‘columns’ -> [columns], ‘data’ -> [values]}
- ‘records’ : list like [{column -> value}, … , {column -> value}]
- ‘index’ : dict like {index -> {column -> value}}
- ‘columns’ : dict like {column -> {index -> value}}
- ‘values’ : just the values array
- ‘table’ : dict like {‘schema’: {schema}, ‘data’: {data}}

Describing the data, where data component is like `orient='records'`.

Changed in version 0.20.0.

date_format [{None, ‘epoch’, ‘iso’}] Type of date conversion. ‘epoch’ = epoch milliseconds, ‘iso’ = ISO8601. The default depends on the `orient`. For `orient='table'`, the default is ‘iso’. For all other orients, the default is ‘epoch’.

double_precision [int, default 10] The number of decimal places to use when encoding floating point values.

force_ascii [bool, default True] Force encoded string to be ASCII.

date_unit [str, default ‘ms’ (milliseconds)] The time unit to encode to, governs timestamp and ISO8601 precision. One of ‘s’, ‘ms’, ‘us’, ‘ns’ for second, millisecond, microsecond, and nanosecond respectively.

default_handler [callable, default None] Handler to call if object cannot otherwise be converted to a suitable format for JSON. Should receive a single argument which is the object to convert and return a serialisable object.

lines [bool, default False] If ‘orient’ is ‘records’ write out line delimited json format. Will throw ValueError if incorrect ‘orient’ since others are not list like.

compression [{‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}] A string representing the compression to use in the output file, only used when the first argument is a filename. By default, the compression is inferred from the filename.

New in version 0.21.0.

Changed in version 0.24.0: ‘infer’ option added and set to default

index [bool, default True] Whether to include the index values in the JSON string. Not including the index (`index=False`) is only supported when orient is ‘split’ or ‘table’.

New in version 0.23.0.

indent [int, optional] Length of whitespace used to indent each record.

New in version 1.0.0.

Returns

None or str If path_or_buf is None, returns the resulting json format as a string. Otherwise returns None.

See also:

[read_json](#)

Notes

The behavior of `indent=0` varies from the stdlib, which does not indent the output but does insert newlines. Currently, `indent=0` and the default `indent=None` are equivalent in pandas, though this may change in a future release.

Examples

```
>>> df = pd.DataFrame([['a', 'b'], ['c', 'd']],
...                     index=['row 1', 'row 2'],
...                     columns=['col 1', 'col 2'])
>>> df.to_json(orient='split')
'{"columns": ["col 1", "col 2"],
 "index": ["row 1", "row 2"],
 "data": [[{"a": "a", "b": "b"}, {"c": "d"}]]}'
```

Encoding/decoding a Dataframe using '`records`' formatted JSON. Note that index labels are not preserved with this encoding.

```
>>> df.to_json(orient='records')
'[{"col 1": "a", "col 2": "b"}, {"col 1": "c", "col 2": "d"}]'
```

Encoding/decoding a Dataframe using '`index`' formatted JSON:

```
>>> df.to_json(orient='index')
'{"row 1": {"col 1": "a", "col 2": "b"}, "row 2": {"col 1": "c", "col 2": "d"}}'
```

Encoding/decoding a Dataframe using '`columns`' formatted JSON:

```
>>> df.to_json(orient='columns')
'{"col 1": {"row 1": "a", "row 2": "c"}, "col 2": {"row 1": "b", "row 2": "d"}}'
```

Encoding/decoding a Dataframe using '`values`' formatted JSON:

```
>>> df.to_json(orient='values')
'[["a", "b"], ["c", "d"]]'
```

Encoding with Table Schema

```
>>> df.to_json(orient='table')
'{"schema": {"fields": [{"name": "index", "type": "string"}, {"name": "col 1", "type": "string"}, {"name": "col 2", "type": "string"}], "primaryKey": "index", "pandas_version": "0.20.0"}, "data": [{"index": "row 1", "col 1": "a", "col 2": "b"}, {"index": "row 2", "col 1": "c", "col 2": "d"}]}'
```

pandas.Series.to_latex

`Series.to_latex(self, buf=None, columns=None, col_space=None, header=True, index=True, na_rep='NaN', formatters=None, float_format=None, sparsify=None, index_names=True, bold_rows=False, column_format=None, longtable=None, escape=None, encoding=None, decimal=',', multicolumn=None, multicolumn_format=None, multirow=None, caption=None, label=None)`

Render object to a LaTeX tabular, longtable, or nested table/tabular.

Requires `\usepackage{booktabs}`. The output can be copy/pasted into a main LaTeX document or read from an external file with `\input{table.tex}`.

Changed in version 0.20.2: Added to Series.

Changed in version 1.0.0: Added caption and label arguments.

Parameters

buf [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.

columns [list of label, optional] The subset of columns to write. Writes all columns by default.

col_space [int, optional] The minimum width of each column.

header [bool or list of str, default True] Write out the column names. If a list of strings is given, it is assumed to be aliases for the column names.

index [bool, default True] Write row names (index).

na_rep [str, default 'NaN'] Missing data representation.

formatters [list of functions or dict of {str: function}, optional] Formatter functions to apply to columns' elements by position or name. The result of each function must be a unicode string. List must be of length equal to the number of columns.

float_format [one-parameter function or str, optional, default None] Formatter for floating point numbers. For example `float_format=".2f"` and `float_format="{:0.2f}"`.format will both result in 0.1234 being formatted as 0.12.

sparsify [bool, optional] Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row. By default, the value will be read from the config module.

index_names [bool, default True] Prints the names of the indexes.

bold_rows [bool, default False] Make the row labels bold in the output.

column_format [str, optional] The columns format as specified in [LaTeX](#) table format e.g. ‘rcl’ for 3 columns. By default, ‘l’ will be used for all columns except columns of numbers, which default to ‘r’.

longtable [bool, optional] By default, the value will be read from the pandas config module. Use a longtable environment instead of tabular. Requires adding a usepackage{longtable} to your [LaTeX](#) preamble.

escape [bool, optional] By default, the value will be read from the pandas config module. When set to False prevents from escaping latex special characters in column names.

encoding [str, optional] A string representing the encoding to use in the output file, defaults to ‘utf-8’.

decimal [str, default ‘.’] Character recognized as decimal separator, e.g. ‘,’ in Europe.

multicolumn [bool, default True] Use multicolumn to enhance MultiIndex columns. The default will be read from the config module.

multicolumn_format [str, default ‘l’] The alignment for multicolumns, similar to *column_format*. The default will be read from the config module.

multirow [bool, default False] Use multirow to enhance MultiIndex rows. Requires adding a usepackage{multirow} to your [LaTeX](#) preamble. Will print centered labels (instead of top-aligned) across the contained rows, separating groups via clines. The default will be read from the pandas config module.

caption [str, optional] The [LaTeX](#) caption to be placed inside \caption{} in the output.

New in version 1.0.0.

label [str, optional] The [LaTeX](#) label to be placed inside \label{} in the output. This is used with \ref{} in the main .tex file.

New in version 1.0.0.

Returns

str or None If buf is None, returns the result as a string. Otherwise returns None.

See also:

[`DataFrame.to_string`](#) Render a DataFrame to a console-friendly tabular output.

[`DataFrame.to_html`](#) Render a DataFrame as an HTML table.

Examples

```
>>> df = pd.DataFrame({'name': ['Raphael', 'Donatello'],
...                      'mask': ['red', 'purple'],
...                      'weapon': ['sai', 'bo staff']})
>>> print(df.to_latex(index=False))
\begin{tabular}{lll}
\toprule
& name & mask & weapon \\
\midrule
Raphael & red & sai \\
Donatello & purple & bo staff \\
\bottomrule

```

(continues on next page)

(continued from previous page)

```
\bottomrule
\end{tabular}
```

pandas.Series.to_list

`Series.to_list(self)`

Return a list of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Times-tamp/Timedelta/Interval/Period)

Returns

`list`

See also:

[numpy.ndarray.tolist](#)

pandas.Series.to_markdown

`Series.to_markdown(self, buf: Union[IO[str], NoneType] = None, mode: Union[str, NoneType] = None, **kwargs) → Union[str, NoneType]`

Print Series in Markdown-friendly format.

New in version 1.0.0.

Parameters

buf [writable buffer, defaults to sys.stdout] Where to send the output. By default, the output is printed to sys.stdout. Pass a writable buffer if you need to further process the output.

mode [str, optional] Mode in which file is opened.

****kwargs** These parameters will be passed to *tabulate*.

Returns

`str` Series in Markdown-friendly format.

Examples

```
>>> s = pd.Series(["elk", "pig", "dog", "quetzal"], name="animal")
>>> print(s.to_markdown())
|   | animal   |
|---:|:-----|
| 0 | elk     |
| 1 | pig     |
| 2 | dog     |
| 3 | quetzal |
```

pandas.Series.to_numpy

```
Series.to_numpy(self, dtype=None, copy=False, na_value=<object object at 0x7f6abd2f350>,  
                **kwargs)
```

A NumPy ndarray representing the values in this Series or Index.

New in version 0.24.0.

Parameters

dtype [str or numpy.dtype, optional] The dtype to pass to `numpy.asarray()`.

copy [bool, default False] Whether to ensure that the returned value is a not a view on another array. Note that `copy=False` does not *ensure* that `to_numpy()` is no-copy. Rather, `copy=True` ensure that a copy is made, even if not strictly necessary.

na_value [Any, optional] The value to use for missing values. The default value depends on `dtype` and the type of the array.

New in version 1.0.0.

****kwargs** Additional keywords passed through to the `to_numpy` method of the underlying array (for extension arrays).

New in version 1.0.0.

Returns

`numpy.ndarray`

See also:

`Series.array` Get the actual data stored within.

`Index.array` Get the actual data stored within.

`DataFrame.to_numpy` Similar method for DataFrame.

Notes

The returned array will be the same up to equality (values equal in `self` will be equal in the returned array; likewise for values that are not equal). When `self` contains an ExtensionArray, the dtype may be different. For example, for a category-dtype Series, `to_numpy()` will return a NumPy array and the categorical dtype will be lost.

For NumPy dtypes, this will be a reference to the actual data stored in this Series or Index (assuming `copy=False`). Modifying the result in place will modify the data stored in the Series or Index (not that we recommend doing that).

For extension types, `to_numpy()` *may* require copying data and coercing the result to a NumPy type (possibly object), which may be expensive. When you need a no-copy reference to the underlying data, `Series.array` should be used instead.

This table lays out the different dtypes and default return types of `to_numpy()` for various dtypes within pandas.

dtype	array type
category[T]	ndarray[T] (same dtype as input)
period	ndarray[object] (Periods)
interval	ndarray[object] (Intervals)
IntegerNA	ndarray[object]
datetime64[ns]	datetime64[ns]
datetime64[ns, tz]	ndarray[object] (Timestamps)

Examples

```
>>> ser = pd.Series(pd.Categorical(['a', 'b', 'a']))
>>> ser.to_numpy()
array(['a', 'b', 'a'], dtype=object)
```

Specify the `dtype` to control how datetime-aware data is represented. Use `dtype=object` to return an ndarray of pandas `Timestamp` objects, each with the correct `tz`.

```
>>> ser = pd.Series(pd.date_range('2000', periods=2, tz="CET"))
>>> ser.to_numpy(dtype=object)
array([Timestamp('2000-01-01 00:00:00+0100', tz='CET', freq='D'),
       Timestamp('2000-01-02 00:00:00+0100', tz='CET', freq='D')],
     dtype=object)
```

Or `dtype='datetime64[ns]'` to return an ndarray of native datetime64 values. The values are converted to UTC and the timezone info is dropped.

```
>>> ser.to_numpy(dtype="datetime64[ns]")
...
array(['1999-12-31T23:00:00.000000000', '2000-01-01T23:00:00...'],
      dtype='datetime64[ns]')
```

pandas.Series.to_period

`Series.to_period(self, freq=None, copy=True)`

Convert Series from DatetimeIndex to PeriodIndex with desired frequency (inferred from index if not passed).

Parameters

`freq` [str, default None] Frequency associated with the PeriodIndex.

`copy` [bool, default True] Whether or not to return a copy.

Returns

`Series` Series with index converted to PeriodIndex.

pandas.Series.to_pickle

`Series.to_pickle(self, path, compression: Union[str, NoneType] = 'infer', protocol: int = 4) → None`
Pickle (serialize) object to file.

Parameters

path [str] File path where the pickled object will be stored.

compression [{‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}, default ‘infer’] A string representing the compression to use in the output file. By default, infers from the file extension in specified path.

protocol [int] Int which indicates which protocol should be used by the pickler, default HIGHEST_PROTOCOL (see [1] paragraph 12.1.2). The possible values are 0, 1, 2, 3, 4. A negative value for the protocol parameter is equivalent to setting its value to HIGHEST_PROTOCOL.

New in version 0.21.0..

See also:

[read_pickle](#) Load pickled pandas object (or any object) from file.

[DataFrame.to_hdf](#) Write DataFrame to an HDF5 file.

[DataFrame.to_sql](#) Write DataFrame to a SQL database.

[DataFrame.to_parquet](#) Write a DataFrame to the binary parquet format.

Examples

```
>>> original_df = pd.DataFrame({ "foo": range(5), "bar": range(5, 10) })
>>> original_df
   foo  bar
0    0    5
1    1    6
2    2    7
3    3    8
4    4    9
>>> original_df.to_pickle("./dummy.pkl")
```

```
>>> unpickled_df = pd.read_pickle("./dummy.pkl")
>>> unpickled_df
   foo  bar
0    0    5
1    1    6
2    2    7
3    3    8
4    4    9
```

```
>>> import os
>>> os.remove("./dummy.pkl")
```

`pandas.Series.to_sql`

`Series.to_sql(self, name: str, con, schema=None, if_exists: str = 'fail', index: bool = True, index_label=None, chunksize=None, dtype=None, method=None) → None`

Write records stored in a DataFrame to a SQL database.

Databases supported by SQLAlchemy [1] are supported. Tables can be newly created, appended to, or overwritten.

Parameters

name [str] Name of SQL table.

con [sqlalchemy.engine.Engine or sqlite3.Connection] Using SQLAlchemy makes it possible to use any DB supported by that library. Legacy support is provided for sqlite3.Connection objects. The user is responsible for engine disposal and connection closure for the SQLAlchemy connectable See [here](#)

schema [str, optional] Specify the schema (if database flavor supports this). If None, use default schema.

if_exists [{‘fail’, ‘replace’, ‘append’}, default ‘fail’] How to behave if the table already exists.

- fail: Raise a ValueError.
- replace: Drop the table before inserting new values.
- append: Insert new values to the existing table.

index [bool, default True] Write DataFrame index as a column. Uses *index_label* as the column name in the table.

index_label [str or sequence, default None] Column label for index column(s). If None is given (default) and *index* is True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.

chunksize [int, optional] Specify the number of rows in each batch to be written at a time. By default, all rows will be written at once.

dtype [dict or scalar, optional] Specifying the datatype for columns. If a dictionary is used, the keys should be the column names and the values should be the SQLAlchemy types or strings for the sqlite3 legacy mode. If a scalar is provided, it will be applied to all columns.

method [{None, ‘multi’, callable}, optional] Controls the SQL insertion clause used:

- None : Uses standard SQL `INSERT` clause (one per row).
- ‘multi’: Pass multiple values in a single `INSERT` clause.
- callable with signature (`pd_table`, `conn`, `keys`, `data_iter`).

Details and a sample callable implementation can be found in the section [insert method](#).

New in version 0.24.0.

Raises

ValueError When the table already exists and *if_exists* is ‘fail’ (the default).

See also:

`read_sql` Read a DataFrame from a table.

Notes

Timezone aware datetime columns will be written as `Timestamp` with `timezone` type with SQLAlchemy if supported by the database. Otherwise, the datetimes will be stored as timezone unaware timestamps local to the original timezone.

New in version 0.24.0.

References

[1], [2]

Examples

Create an in-memory SQLite database.

```
>>> from sqlalchemy import create_engine
>>> engine = create_engine('sqlite://', echo=False)
```

Create a table from scratch with 3 rows.

```
>>> df = pd.DataFrame({'name' : ['User 1', 'User 2', 'User 3']})
>>> df
   name
0  User 1
1  User 2
2  User 3
```

```
>>> df.to_sql('users', con=engine)
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 1'), (1, 'User 2'), (2, 'User 3')]
```

```
>>> df1 = pd.DataFrame({'name' : ['User 4', 'User 5']})
>>> df1.to_sql('users', con=engine, if_exists='append')
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 1'), (1, 'User 2'), (2, 'User 3'),
 (0, 'User 4'), (1, 'User 5')]
```

Overwrite the table with just `df1`.

```
>>> df1.to_sql('users', con=engine, if_exists='replace',
...             index_label='id')
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 4'), (1, 'User 5')]
```

Specify the `dtype` (especially useful for integers with missing values). Notice that while pandas is forced to store the data as floating point, the database supports nullable integers. When fetching the data with Python, we get back integer scalars.

```
>>> df = pd.DataFrame({'A': [1, None, 2]})
>>> df
   A
0  1.0
1  NaN
2  2.0
```

```
>>> from sqlalchemy.types import Integer
>>> df.to_sql('integers', con=engine, index=False,
...             dtype={"A": Integer()})
```

```
>>> engine.execute("SELECT * FROM integers").fetchall()
[(1,), (None,), (2,)]
```

pandas.Series.to_string

`Series.to_string(self, buf=None, na_rep='NaN', float_format=None, header=True, index=True, length=False, dtype=False, name=False, max_rows=None, min_rows=None)`
Render a string representation of the Series.

Parameters

buf [StringIO-like, optional] Buffer to write to.
na_rep [str, optional] String representation of NaN to use, default ‘NaN’.
float_format [one-parameter function, optional] Formatter function to apply to columns’ elements if they are floats, default None.
header [bool, default True] Add the Series header (index name).
index [bool, optional] Add index (row) labels, default True.
length [bool, default False] Add the Series length.
dtype [bool, default False] Add the Series dtype.
name [bool, default False] Add the Series name if not None.
max_rows [int, optional] Maximum number of rows to show before truncating. If None, show all.
min_rows [int, optional] The number of rows to display in a truncated repr (when number of rows is above *max_rows*).

Returns

str or None String representation of Series if `buf=None`, otherwise None.

pandas.Series.to_timestamp

`Series.to_timestamp(self, freq=None, how='start', copy=True)`
Cast to DatetimeIndex of Timestamps, at *beginning* of period.

Parameters

freq [str, default frequency of PeriodIndex] Desired frequency.
how [{‘s’, ‘e’, ‘start’, ‘end’}] Convention for converting period to timestamp; start of period vs. end.
copy [bool, default True] Whether or not to return a copy.

Returns

Series with DatetimeIndex

pandas.Series.to_xarray

`Series.to_xarray(self)`

Return an xarray object from the pandas object.

Returns

xarray.DataArray or xarray.Dataset Data in the pandas structure converted to Dataset if the object is a DataFrame, or a DataArray if the object is a Series.

See also:

`DataFrame.to_hdf` Write DataFrame to an HDF5 file.

`DataFrame.to_parquet` Write a DataFrame to the binary parquet format.

Notes

See the [xarray docs](#)

Examples

```
>>> df = pd.DataFrame([{'falcon': 'bird', 389.0, 2},
...                     ('parrot', 'bird', 24.0, 2),
...                     ('lion', 'mammal', 80.5, 4),
...                     ('monkey', 'mammal', np.nan, 4)],
...                     columns=['name', 'class', 'max_speed',
...                               'num_legs'])
>>> df
   name    class  max_speed  num_legs
0  falcon     bird      389.0        2
1  parrot     bird       24.0        2
2    lion  mammal       80.5        4
3  monkey  mammal        NaN        4
```

```
>>> df.to_xarray()
<xarray.Dataset>
Dimensions:  (index: 4)
Coordinates:

    speed      (date, animal) int64 350 18 361 15
```

pandas.Series.tolist

Series.tolist(self)

Return a list of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

Returns

list

See also:

[numpy.ndarray.tolist](#)

pandas.Series.transform

Series.transform(self, func, axis=0, *args, **kwargs)

Call func on self producing a Series with transformed values.

Produced Series will have same axis length as self.

Parameters

func [function, str, list or dict] Function to use for transforming the data. If a function, must either work when passed a Series or when passed to Series.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. [np.exp, 'sqrt']

- dict of axis labels -> functions, function names or list of such.

axis [{0 or ‘index’}] Parameter needed for compatibility with DataFrame.

***args** Positional arguments to pass to *func*.

****kwargs** Keyword arguments to pass to *func*.

Returns

Series A Series that must have the same length as self.

Raises

ValueError [If the returned Series has a different length than self.]

See also:

[**Series.agg**](#) Only perform aggregating type operations.

[**Series.apply**](#) Invoke function on a Series.

Examples

```
>>> df = pd.DataFrame({ 'A': range(3), 'B': range(1, 4) })
>>> df
   A  B
0  0  1
1  1  2
2  2  3
>>> df.transform(lambda x: x + 1)
   A  B
0  1  2
1  2  3
2  3  4
```

Even though the resulting Series must have the same length as the input Series, it is possible to provide several input functions:

```
>>> s = pd.Series(range(3))
>>> s
0    0
1    1
2    2
dtype: int64
>>> s.transform([np.sqrt, np.exp])
      sqrt        exp
0  0.000000  1.000000
1  1.000000  2.718282
2  1.414214  7.389056
```

pandas.Series.transpose

`Series.transpose(self, *args, **kwargs)`

Return the transpose, which is by definition self.

Returns

`%(klass)s`

pandas.Series.truediv

`Series.truediv(self, other, level=None, fill_value=None, axis=0)`

Return Floating division of series and other, element-wise (binary operator *truediv*).

Equivalent to `series / other`, but with support to substitute a `fill_value` for missing data in one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

`Series.rtruediv`

Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.divide(b, fill_value=0)
a    1.0
b    inf
c    inf
```

(continues on next page)

(continued from previous page)

```
d    0.0
e    NaN
dtype: float64
```

pandas.Series.truncate

`Series.truncate(self: ~FrameOrSeries, before=None, after=None, axis=None, copy: bool = True) → ~FrameOrSeries`

Truncate a Series or DataFrame before and after some index value.

This is a useful shorthand for boolean indexing based on index values above or below certain thresholds.

Parameters

`before` [date, str, int] Truncate all rows before this index value.

`after` [date, str, int] Truncate all rows after this index value.

`axis` [{0 or ‘index’, 1 or ‘columns’}, optional] Axis to truncate. Truncates the index (rows) by default.

`copy` [bool, default is True,] Return a copy of the truncated section.

Returns

`type of caller` The truncated Series or DataFrame.

See also:

`DataFrame.loc` Select a subset of a DataFrame by label.

`DataFrame.iloc` Select a subset of a DataFrame by position.

Notes

If the index being truncated contains only datetime values, `before` and `after` may be specified as strings instead of Timestamps.

Examples

```
>>> df = pd.DataFrame({'A': ['a', 'b', 'c', 'd', 'e'],
...                     'B': ['f', 'g', 'h', 'i', 'j'],
...                     'C': ['k', 'l', 'm', 'n', 'o']},
...                     index=[1, 2, 3, 4, 5])
>>> df
   A  B  C
1  a  f  k
2  b  g  l
3  c  h  m
4  d  i  n
5  e  j  o
```

```
>>> df.truncate(before=2, after=4)
   A  B  C
2  b  g  l
```

(continues on next page)

(continued from previous page)

```
3   c   h   m  
4   d   i   n
```

The columns of a DataFrame can be truncated.

```
>>> df.truncate(before="A", after="B", axis="columns")  
      A   B  
1   a   f  
2   b   g  
3   c   h  
4   d   i  
5   e   j
```

For Series, only rows can be truncated.

```
>>> df['A'].truncate(before=2, after=4)  
2   b  
3   c  
4   d  
Name: A, dtype: object
```

The index values in truncate can be datetimes or string dates.

```
>>> dates = pd.date_range('2016-01-01', '2016-02-01', freq='s')  
>>> df = pd.DataFrame(index=dates, data={'A': 1})  
>>> df.tail()  
              A  
2016-01-31 23:59:56  1  
2016-01-31 23:59:57  1  
2016-01-31 23:59:58  1  
2016-01-31 23:59:59  1  
2016-02-01 00:00:00  1
```

```
>>> df.truncate(before=pd.Timestamp('2016-01-05'),  
...                 after=pd.Timestamp('2016-01-10')).tail()  
              A  
2016-01-09 23:59:56  1  
2016-01-09 23:59:57  1  
2016-01-09 23:59:58  1  
2016-01-09 23:59:59  1  
2016-01-10 00:00:00  1
```

Because the index is a DatetimeIndex containing only dates, we can specify *before* and *after* as strings. They will be coerced to Timestamps before truncation.

```
>>> df.truncate('2016-01-05', '2016-01-10').tail()  
              A  
2016-01-09 23:59:56  1  
2016-01-09 23:59:57  1  
2016-01-09 23:59:58  1  
2016-01-09 23:59:59  1  
2016-01-10 00:00:00  1
```

Note that truncate assumes a 0 value for any unspecified time component (midnight). This differs from partial string slicing, which returns any partially matching dates.

```
>>> df.loc['2016-01-05':'2016-01-10', :].tail()
   A
2016-01-10 23:59:55    1
2016-01-10 23:59:56    1
2016-01-10 23:59:57    1
2016-01-10 23:59:58    1
2016-01-10 23:59:59    1
```

pandas.Series.tshift

`Series.tshift(self: ~FrameOrSeries, periods: int = 1, freq=None, axis=0) → ~FrameOrSeries`
Shift the time index, using the index's frequency if available.

Parameters

periods [int] Number of periods to move, can be positive or negative.
freq [DateOffset, timedelta, or str, default None] Increment to use from the tseries module or time rule expressed as a string (e.g. 'EOM').
axis [{0 or 'index', 1 or 'columns', None}, default 0] Corresponds to the axis that contains the Index.

Returns

shifted [Series/DataFrame]

Notes

If freq is not specified then tries to use the freq or inferred_freq attributes of the index. If neither of those attributes exist, a ValueError is thrown

pandas.Series.tz_convert

`Series.tz_convert(self: ~FrameOrSeries, tz, axis=0, level=None, copy: bool = True) → ~FrameOrSeries`
Convert tz-aware axis to target time zone.

Parameters

tz [str or tzinfo object]
axis [the axis to convert]
level [int, str, default None] If axis is a MultiIndex, convert a specific level. Otherwise must be None.
copy [bool, default True] Also make a copy of the underlying data.

Returns

%(klass)s Object with time zone converted axis.

Raises

TypeError If the axis is tz-naive.

`pandas.Series.tz_localize`

```
Series.tz_localize(self: ~FrameOrSeries, tz, axis=0, level=None, copy: bool = True, ambiguous='raise', nonexistent: str = 'raise') → ~FrameOrSeries  
Localize tz-naive index of a Series or DataFrame to target time zone.
```

This operation localizes the Index. To localize the values in a timezone-naive Series, use `Series.dt.tz_localize()`.

Parameters

tz [str or tzinfo]

axis [the axis to localize]

level [int, str, default None] If axis ia a MultiIndex, localize a specific level. Otherwise must be None.

copy [bool, default True] Also make a copy of the underlying data.

ambiguous ['infer', bool-ndarray, 'NaT', default 'raise'] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the *ambiguous* parameter dictates how ambiguous times should be handled.

- 'infer' will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- 'NaT' will return NaT where there are ambiguous times
- 'raise' will raise an AmbiguousTimeError if there are ambiguous times.

nonexistent [str, default 'raise'] A nonexistent time does not exist in a particular time-zone where clocks moved forward due to DST. Valid values are:

- 'shift_forward' will shift the nonexistent time forward to the closest existing time
- 'shift_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

Returns

Series or DataFrame Same type as the input.

Raises

TypeError If the TimeSeries is tz-aware and tz is not None.

Examples

Localize local times:

```
>>> s = pd.Series([1],
...                 index=pd.DatetimeIndex(['2018-09-15 01:30:00']))
>>> s.tz_localize('CET')
2018-09-15 01:30:00+02:00    1
dtype: int64
```

Be careful with DST changes. When there is sequential data, pandas can infer the DST time:

```
>>> s = pd.Series(range(7),
...                 index=pd.DatetimeIndex(['2018-10-28 01:30:00',
...                                         '2018-10-28 02:00:00',
...                                         '2018-10-28 02:30:00',
...                                         '2018-10-28 02:00:00',
...                                         '2018-10-28 02:30:00',
...                                         '2018-10-28 03:00:00',
...                                         '2018-10-28 03:30:00']))
>>> s.tz_localize('CET', ambiguous='infer')
2018-10-28 01:30:00+02:00    0
2018-10-28 02:00:00+02:00    1
2018-10-28 02:30:00+02:00    2
2018-10-28 02:00:00+01:00    3
2018-10-28 02:30:00+01:00    4
2018-10-28 03:00:00+01:00    5
2018-10-28 03:30:00+01:00    6
dtype: int64
```

In some cases, inferring the DST is impossible. In such cases, you can pass an ndarray to the `ambiguous` parameter to set the DST explicitly

```
>>> s = pd.Series(range(3),
...                 index=pd.DatetimeIndex(['2018-10-28 01:20:00',
...                                         '2018-10-28 02:36:00',
...                                         '2018-10-28 03:46:00']))
>>> s.tz_localize('CET', ambiguous=np.array([True, True, False]))
2018-10-28 01:20:00+02:00    0
2018-10-28 02:36:00+02:00    1
2018-10-28 03:46:00+01:00    2
dtype: int64
```

If the DST transition causes nonexistent times, you can shift these dates forward or backwards with a `timedelta` object or '`shift_forward`' or '`shift_backward`'. >>> s = pd.Series(range(2), ... index=pd.DatetimeIndex(['2015-03-29 02:30:00', ... '2015-03-29 03:30:00'])) >>> s.tz_localize('Europe/Warsaw', nonexistent='shift_forward') 2015-03-29 03:00:00+02:00 0 2015-03-29 03:30:00+02:00 1 dtype: int64 >>> s.tz_localize('Europe/Warsaw', nonexistent='shift_backward') 2015-03-29 01:59:59.999999999+01:00 0 2015-03-29 03:30:00+02:00 1 dtype: int64 >>> s.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta('1H')) 2015-03-29 03:30:00+02:00 0 2015-03-29 03:30:00+02:00 1 dtype: int64

pandas.Series.unique

`Series.unique(self)`

Return unique values of Series object.

Uniques are returned in order of appearance. Hash table-based unique, therefore does NOT sort.

Returns

ndarray or ExtensionArray The unique values returned as a NumPy array. See Notes.

See also:

[`unique`](#) Top-level unique method for any 1-d array-like object.

[`Index.unique`](#) Return Index with unique values from an Index object.

Notes

Returns the unique values as a NumPy array. In case of an extension-array backed Series, a new `ExtensionArray` of that type with just the unique values is returned. This includes

- Categorical
- Period
- Datetime with Timezone
- Interval
- Sparse
- IntegerNA

See Examples section.

Examples

```
>>> pd.Series([2, 1, 3, 3], name='A').unique()
array([2, 1, 3])
```

```
>>> pd.Series([pd.Timestamp('2016-01-01') for _ in range(3)]).unique()
array(['2016-01-01T00:00:00.000000000'], dtype='datetime64[ns]')
```

```
>>> pd.Series([pd.Timestamp('2016-01-01', tz='US/Eastern')
...             for _ in range(3)]).unique()
<DatetimeArray>
['2016-01-01 00:00:00-05:00']
Length: 1, dtype: datetime64[ns, US/Eastern]
```

An unordered Categorical will return categories in the order of appearance.

```
>>> pd.Series(pd.Categorical(list('baabc'))).unique()
[b, a, c]
Categories (3, object): [b, a, c]
```

An ordered Categorical preserves the category ordering.

```
>>> pd.Series(pd.Categorical(list('baabc'), categories=list('abc'),
...                               ordered=True)).unique()
[b, a, c]
Categories (3, object): [a < b < c]
```

pandas.Series.unstack

`Series.unstack (self, level=-1, fill_value=None)`

Unstack, a.k.a. pivot, Series with MultiIndex to produce DataFrame. The level involved will automatically get sorted.

Parameters

level [int, str, or list of these, default last level] Level(s) to unstack, can pass level name.

fill_value [scalar value, default None] Value to use when replacing NaN values.

Returns

DataFrame Unstacked Series.

Examples

```
>>> s = pd.Series([1, 2, 3, 4],
...                 index=pd.MultiIndex.from_product([('one', 'two'),
...                                         ['a', 'b']]))
>>> s
one   a    1
      b    2
two   a    3
      b    4
dtype: int64
```

```
>>> s.unstack(level=-1)
      a   b
one  1   2
two  3   4
```

```
>>> s.unstack(level=0)
      one   two
a     1     3
b     2     4
```

pandas.Series.update

`Series.update (self, other)`

Modify Series in place using non-NA values from passed Series. Aligns on index.

Parameters

other [Series]

Examples

```
>>> s = pd.Series([1, 2, 3])
>>> s.update(pd.Series([4, 5, 6]))
>>> s
0    4
1    5
2    6
dtype: int64
```

```
>>> s = pd.Series(['a', 'b', 'c'])
>>> s.update(pd.Series(['d', 'e'], index=[0, 2]))
>>> s
0    d
1    b
2    e
dtype: object
```

```
>>> s = pd.Series([1, 2, 3])
>>> s.update(pd.Series([4, 5, 6, 7, 8]))
>>> s
0    4
1    5
2    6
dtype: int64
```

If `other` contains NaNs the corresponding values are not updated in the original Series.

```
>>> s = pd.Series([1, 2, 3])
>>> s.update(pd.Series([4, np.nan, 6]))
>>> s
0    4
1    2
2    6
dtype: int64
```

pandas.Series.value_counts

`Series.value_counts(self, normalize=False, sort=True, ascending=False, bins=None, dropna=True)`

Return a Series containing counts of unique values.

The resulting object will be in descending order so that the first element is the most frequently-occurring element. Excludes NA values by default.

Parameters

normalize [bool, default False] If True then the object returned will contain the relative frequencies of the unique values.

sort [bool, default True] Sort by frequencies.

ascending [bool, default False] Sort in ascending order.

bins [int, optional] Rather than count values, group them into half-open bins, a convenience for `pd.cut`, only works with numeric data.

dropna [bool, default True] Don't include counts of NaN.

Returns**Series****See also:*****Series.count*** Number of non-NA elements in a Series.***DataFrame.count*** Number of non-NA elements in a DataFrame.**Examples**

```
>>> index = pd.Index([3, 1, 2, 3, 4, np.nan])
>>> index.value_counts()
3.0      2
4.0      1
2.0      1
1.0      1
dtype: int64
```

With *normalize* set to *True*, returns the relative frequency by dividing all values by the sum of values.

```
>>> s = pd.Series([3, 1, 2, 3, 4, np.nan])
>>> s.value_counts(normalize=True)
3.0      0.4
4.0      0.2
2.0      0.2
1.0      0.2
dtype: float64
```

bins

Bins can be useful for going from a continuous variable to a categorical variable; instead of counting unique apparitions of values, divide the index in the specified number of half-open bins.

```
>>> s.value_counts(bins=3)
(2.0, 3.0]      2
(0.996, 2.0]    2
(3.0, 4.0]      1
dtype: int64
```

dropna

With *dropna* set to *False* we can also see NaN index values.

```
>>> s.value_counts(dropna=False)
3.0      2
NaN      1
4.0      1
2.0      1
1.0      1
dtype: int64
```

pandas.Series.var

`Series.var(self, axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs)`
Return unbiased variance over requested axis.

Normalized by N-1 by default. This can be changed using the ddof argument

Parameters

axis [{index (0)}]

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns

scalar or Series (if level specified)

pandas.Series.view

`Series.view(self, dtype=None)`
Create a new view of the Series.

This function will return a new Series with a view of the same underlying values in memory, optionally reinterpreted with a new data type. The new data type must preserve the same size in bytes as to not cause index misalignment.

Parameters

dtype [data type] Data type object or one of their string representations.

Returns

Series A new Series object as a view of the same data in memory.

See also:

[numpy.ndarray.view](#) Equivalent numpy function to create a new view of the same data in memory.

Notes

Series are instantiated with `dtype=float64` by default. While `numpy.ndarray.view()` will return a view with the same data type as the original array, `Series.view()` (without specified `dtype`) will try using `float64` and may fail if the original data type size in bytes is not the same.

Examples

```
>>> s = pd.Series([-2, -1, 0, 1, 2], dtype='int8')
>>> s
0    -2
1    -1
2     0
3     1
4     2
dtype: int8
```

The 8 bit signed integer representation of `-1` is `0b11111111`, but the same bytes represent 255 if read as an 8 bit unsigned integer:

```
>>> us = s.view('uint8')
>>> us
0    254
1    255
2     0
3     1
4     2
dtype: uint8
```

The views share the same underlying values:

```
>>> us[0] = 128
>>> s
0   -128
1     -1
2      0
3      1
4      2
dtype: int8
```

pandas.Series.where

`Series.where(self, cond, other=nan, inplace=False, axis=None, level=None, errors='raise', try_cast=False)`

Replace values where the condition is False.

Parameters

cond [bool Series/DataFrame, array-like, or callable] Where `cond` is True, keep the original value. Where False, replace with corresponding value from `other`. If `cond` is callable, it is computed on the Series/DataFrame and should return boolean Series/DataFrame or array. The callable must not change input Series/DataFrame (though pandas doesn't check it).

other [scalar, Series/DataFrame, or callable] Entries where `cond` is False are replaced with corresponding value from `other`. If `other` is callable, it is computed on the Series/DataFrame and should return scalar or Series/DataFrame. The callable must not change input Series/DataFrame (though pandas doesn't check it).

inplace [bool, default False] Whether to perform the operation in place on the data.

axis [int, default None] Alignment axis if needed.

level [int, default None] Alignment level if needed.

errors [str, {'raise', 'ignore'}, default 'raise'] Note that currently this parameter won't affect the results and will always coerce to a suitable dtype.

- 'raise' : allow exceptions to be raised.
- 'ignore' : suppress exceptions. On error return original object.

try_cast [bool, default False] Try to cast the result back to the input type (if possible).

Returns

Same type as caller

See also:

[DataFrame.mask\(\)](#) Return an object of same shape as self.

Notes

The where method is an application of the if-then idiom. For each element in the calling DataFrame, if cond is True the element is used; otherwise the corresponding element from the DataFrame other is used.

The signature for [DataFrame.where\(\)](#) differs from [numpy.where\(\)](#). Roughly df1.where(m, df2) is equivalent to np.where(m, df1, df2).

For further details and examples see the where documentation in [indexing](#).

Examples

```
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0      NaN
1      1.0
2      2.0
3      3.0
4      4.0
dtype: float64
```

```
>>> s.mask(s > 0)
0      0.0
1      NaN
2      NaN
3      NaN
4      NaN
dtype: float64
```

```
>>> s.where(s > 1, 10)
0      10
1      10
2       2
3       3
4       4
dtype: int64
```

```
>>> df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=['A', 'B'])
>>> df
   A    B
0  0    1
1  2    3
2  4    5
3  6    7
4  8    9
>>> m = df % 3 == 0
>>> df.where(m, -df)
   A    B
0  0   -1
1 -2    3
2 -4   -5
3  6   -7
4 -8    9
>>> df.where(m, -df) == np.where(m, df, -df)
   A      B
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True
>>> df.where(m, -df) == df.mask(~m, -df)
   A      B
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True
```

pandas.Series.xs

`Series.xs(self, key, axis=0, level=None, drop_level: bool = True)`

Return cross-section from the Series/DataFrame.

This method takes a `key` argument to select data at a particular level of a MultiIndex.

Parameters

`key` [label or tuple of label] Label contained in the index, or partially in a MultiIndex.

`axis` [{0 or ‘index’, 1 or ‘columns’}, default 0] Axis to retrieve cross-section on.

`level` [object, defaults to first n levels (n=1 or len(key))] In case of a key partially contained in a MultiIndex, indicate which levels are used. Levels can be referred by label or position.

`drop_level` [bool, default True] If False, returns object with same levels as self.

Returns

Series or DataFrame Cross-section from the original Series or DataFrame corresponding to the selected index levels.

See also:

`DataFrame.loc` Access a group of rows and columns by label(s) or a boolean array.

`DataFrame.iloc` Purely integer-location based indexing for selection by position.

Notes

`xs` can not be used to set values.

MultiIndex Slicers is a generic way to get/set values on any level or levels. It is a superset of `xs` functionality, see [MultiIndex Slicers](#).

Examples

```
>>> d = {'num_legs': [4, 4, 2, 2],
...        'num_wings': [0, 0, 2, 2],
...        'class': ['mammal', 'mammal', 'mammal', 'bird'],
...        'animal': ['cat', 'dog', 'bat', 'penguin'],
...        'locomotion': ['walks', 'walks', 'flies', 'walks']}
>>> df = pd.DataFrame(data=d)
>>> df = df.set_index(['class', 'animal', 'locomotion'])
>>> df
          num_legs  num_wings
class animal locomotion
mammal cat      walks        4      0
        dog      walks        4      0
        bat      flies        2      2
bird   penguin walks        2      2
```

Get values at specified index

```
>>> df.xs('mammal')
          num_legs  num_wings
animal locomotion
cat      walks        4      0
dog      walks        4      0
bat      flies        2      2
```

Get values at several indexes

```
>>> df.xs(('mammal', 'dog'))
          num_legs  num_wings
locomotion
walks        4      0
```

Get values at specified index and level

```
>>> df.xs('cat', level=1)
          num_legs  num_wings
class locomotion
mammal walks        4      0
```

Get values at several indexes and levels

```
>>> df.xs(('bird', 'walks'),
...         level=[0, 'locomotion'])
          num_legs  num_wings
animal
penguin      2      2
```

Get values at specified column and axis

```
>>> df.xs('num_wings', axis=1)
      class   animal  locomotion
mammal    cat     walks      0
          dog     walks      0
          bat     flies      2
bird      penguin  walks      2
Name: num_wings, dtype: int64
```

4.3.2 Attributes

Axes

<code>Series.index</code>	The index (axis labels) of the Series.
<code>Series.array</code>	The ExtensionArray of the data backing this Series or Index.
<code>Series.values</code>	Return Series as ndarray or ndarray-like depending on the dtype.
<code>Series.dtype</code>	Return the dtype object of the underlying data.
<code>Series.shape</code>	Return a tuple of the shape of the underlying data.
<code>Series nbytes</code>	Return the number of bytes in the underlying data.
<code>Series.ndim</code>	Number of dimensions of the underlying data, by definition 1.
<code>Series.size</code>	Return the number of elements in the underlying data.
<code>Series.T</code>	Return the transpose, which is by definition self.
<code>Series.memory_usage(self[, index, deep])</code>	Return the memory usage of the Series.
<code>Series.hasnans</code>	Return if I have any nans; enables various perf speedups.
<code>Series.empty</code>	
<code>Series.dtypes</code>	Return the dtype object of the underlying data.
<code>Series.name</code>	

pandas.Series.empty

property `Series.empty`

pandas.Series.name**property Series.name**

4.3.3 Conversion

<code>Series.astype(self, dtype, copy, errors)</code>	Cast a pandas object to a specified dtype <code>dtype</code> .
<code>Series.convert_dtypes(self, infer_objects, ...)</code>	Convert columns to best possible dtypes using dtypes supporting <code>pd.NA</code> .
<code>Series.infer_objects(self)</code>	Attempt to infer better dtypes for object columns.
<code>Series.copy(self, deep)</code>	Make a copy of this object's indices and data.
<code>Series.bool(self)</code>	Return the bool of a single element PandasObject.
<code>Series.to_numpy(self[, dtype, copy, na_value])</code>	A NumPy ndarray representing the values in this Series or Index.
<code>Series.to_period(self[, freq, copy])</code>	Convert Series from DatetimeIndex to PeriodIndex with desired frequency (inferred from index if not passed).
<code>Series.to_timestamp(self[, freq, how, copy])</code>	Cast to DatetimeIndex of Timestamps, at <i>beginning</i> of period.
<code>Series.to_list(self)</code>	Return a list of the values.
<code>Series.__array__(self[, dtype])</code>	Return the values as a NumPy array.

pandas.Series.__array__`Series.__array__(self, dtype=None) → numpy.ndarray`

Return the values as a NumPy array.

Users should not call this directly. Rather, it is invoked by `numpy.array()` and `numpy.asarray()`.**Parameters****dtype** [str or numpy.dtype, optional] The dtype to use for the resulting NumPy array. By default, the dtype is inferred from the data.**Returns****numpy.ndarray** The values in the series converted to a `numpy.ndarray` with the specified `dtype`.**See also:**`array` Create a new array from data.`Series.array` Zero-copy view to the array backing the Series.`Series.to_numpy` Series method for similar behavior.**Examples**

```
>>> ser = pd.Series([1, 2, 3])
>>> np.asarray(ser)
array([1, 2, 3])
```

For timezone-aware data, the timezones may be retained with `dtype='object'`

```
>>> tzser = pd.Series(pd.date_range('2000', periods=2, tz="CET"))
>>> np.asarray(tzser, dtype="object")
```

(continues on next page)

(continued from previous page)

```
array([Timestamp('2000-01-01 00:00:00+0100', tz='CET', freq='D'),
       Timestamp('2000-01-02 00:00:00+0100', tz='CET', freq='D')]),
      dtype=object)
```

Or the values may be localized to UTC and the tzinfo discarded with `dtype='datetime64[ns]'`

```
>>> np.asarray(tzser, dtype="datetime64[ns]")
array(['1999-12-31T23:00:00.000000000', ...],
      dtype='datetime64[ns]')
```

4.3.4 Indexing, iteration

<code>Series.get(self, key[, default])</code>	Get item from object for given key (ex: DataFrame column).
<code>Series.at</code>	Access a single value for a row/column label pair.
<code>Series.iat</code>	Access a single value for a row/column pair by integer position.
<code>Series.loc</code>	Access a group of rows and columns by label(s) or a boolean array.
<code>Series.iloc</code>	Purely integer-location based indexing for selection by position.
<code>Series.__iter__(self)</code>	Return an iterator of the values.
<code>Series.items(self)</code>	Lazily iterate over (index, value) tuples.
<code>Series.iteritems(self)</code>	Lazily iterate over (index, value) tuples.
<code>Series.keys(self)</code>	Return alias for index.
<code>Series.pop(self, item)</code>	Return item and drop from frame.
<code>Series.item(self)</code>	Return the first element of the underlying data as a python scalar.
<code>Series.xs(self, key[, axis, level])</code>	Return cross-section from the Series/DataFrame.

pandas.Series.__iter__

`Series.__iter__(self)`

Return an iterator of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Times-Tamp/Timedelta/Interval/Period)

Returns

iterator

For more information on .at, .iat, .loc, and .iloc, see the [indexing documentation](#).

4.3.5 Binary operator functions

<code>Series.add(self, other[, level, fill_value, ...])</code>	Return Addition of series and other, element-wise (binary operator <i>add</i>).
<code>Series.sub(self, other[, level, fill_value, ...])</code>	Return Subtraction of series and other, element-wise (binary operator <i>sub</i>).
<code>Series.mul(self, other[, level, fill_value, ...])</code>	Return Multiplication of series and other, element-wise (binary operator <i>mul</i>).
<code>Series.div(self, other[, level, fill_value, ...])</code>	Return Floating division of series and other, element-wise (binary operator <i>truediv</i>).
<code>Series.truediv(self, other[, level, ...])</code>	Return Floating division of series and other, element-wise (binary operator <i>truediv</i>).
<code>Series.floordiv(self, other[, level, ...])</code>	Return Integer division of series and other, element-wise (binary operator <i>floordiv</i>).
<code>Series.mod(self, other[, level, fill_value, ...])</code>	Return Modulo of series and other, element-wise (binary operator <i>mod</i>).
<code>Series.pow(self, other[, level, fill_value, ...])</code>	Return Exponential power of series and other, element-wise (binary operator <i>pow</i>).
<code>Series.radd(self, other[, level, ...])</code>	Return Addition of series and other, element-wise (binary operator <i>radd</i>).
<code>Series.rsub(self, other[, level, ...])</code>	Return Subtraction of series and other, element-wise (binary operator <i>rsub</i>).
<code>Series.rmul(self, other[, level, ...])</code>	Return Multiplication of series and other, element-wise (binary operator <i>rmul</i>).
<code>Series.rdiv(self, other[, level, ...])</code>	Return Floating division of series and other, element-wise (binary operator <i>rtruediv</i>).
<code>Series.rtruediv(self, other[, level, ...])</code>	Return Floating division of series and other, element-wise (binary operator <i>rtruediv</i>).
<code>Series.rfloordiv(self, other[, level, ...])</code>	Return Integer division of series and other, element-wise (binary operator <i>rfloordiv</i>).
<code>Series.rmod(self, other[, level, ...])</code>	Return Modulo of series and other, element-wise (binary operator <i>rmod</i>).
<code>Series.rpow(self, other[, level, ...])</code>	Return Exponential power of series and other, element-wise (binary operator <i>rpow</i>).
<code>Series.combine(self, other, func[, fill_value])</code>	Combine the Series with a Series or scalar according to <i>func</i> .
<code>Series.combine_first(self, other)</code>	Combine Series values, choosing the calling Series's values first.
<code>Series.round(self[, decimals])</code>	Round each value in a Series to the given number of decimals.
<code>Series.lt(self, other[, level, fill_value, axis])</code>	Return Less than of series and other, element-wise (binary operator <i>lt</i>).
<code>Series.gt(self, other[, level, fill_value, axis])</code>	Return Greater than of series and other, element-wise (binary operator <i>gt</i>).
<code>Series.le(self, other[, level, fill_value, axis])</code>	Return Less than or equal to of series and other, element-wise (binary operator <i>le</i>).
<code>Series.ge(self, other[, level, fill_value, axis])</code>	Return Greater than or equal to of series and other, element-wise (binary operator <i>ge</i>).
<code>Series.ne(self, other[, level, fill_value, axis])</code>	Return Not equal to of series and other, element-wise (binary operator <i>ne</i>).

Continued on next page

Table 34 – continued from previous page

<code>Series.eq(self, other[, level, fill_value, axis])</code>	Return Equal to of series and other, element-wise (binary operator <code>eq</code>).
<code>Series.product(self[, axis, skipna, level, ...])</code>	Return the product of the values for the requested axis.
<code>Series.dot(self, other)</code>	Compute the dot product between the Series and the columns of other.

4.3.6 Function application, groupby & window

<code>Series.apply(func[, convert_dtype, args])</code>	Invoke function on values of Series.
<code>Series.agg(func[, axis])</code>	Aggregate using one or more operations over the specified axis.
<code>Series.aggregate(func[, axis])</code>	Aggregate using one or more operations over the specified axis.
<code>Series.transform(func[, axis])</code>	Call <code>func</code> on self producing a Series with transformed values.
<code>Series.map(arg[, na_action])</code>	Map values of Series according to input correspondence.
<code>Series.groupby(by[, axis, level])</code>	Group Series using a mapper or by a Series of columns.
<code>Series.rolling(window[, min_periods, ...])</code>	Provide rolling window calculations.
<code>Series.expanding(min_periods, ...))</code>	Provide expanding transformations.
<code>Series.ewm(com, span, halflife, ...))</code>	Provide exponential weighted functions.
<code>Series.pipe(func, *args, **kwargs)</code>	Apply <code>func(self, *args, **kwargs)</code> .

4.3.7 Computations / descriptive stats

<code>Series.abs()</code>	Return a Series/DataFrame with absolute numeric value of each element.
<code>Series.all(axis, bool_only, skipna, ...))</code>	Return whether all elements are True, potentially over an axis.
<code>Series.any(axis, bool_only, skipna, ...))</code>	Return whether any element is True, potentially over an axis.
<code>Series.autocorr(lag)</code>	Compute the lag-N autocorrelation.
<code>Series.between(left, right[, inclusive])</code>	Return boolean Series equivalent to <code>left <= series <= right</code> .
<code>Series.clip(lower, upper, axis)</code>	Trim values at input threshold(s).
<code>Series.corr(other[, method, min_periods])</code>	Compute correlation with <code>other</code> Series, excluding missing values.
<code>Series.count(level)</code>	Return number of non-NA/null observations in the Series.
<code>Series.cov(other[, min_periods])</code>	Compute covariance with Series, excluding missing values.
<code>Series.cummax(axis, skipna)</code>	Return cumulative maximum over a DataFrame or Series axis.
<code>Series.cummin(axis, skipna)</code>	Return cumulative minimum over a DataFrame or Series axis.
<code>Series.cumprod(axis, skipna)</code>	Return cumulative product over a DataFrame or Series axis.

Continued on next page

Table 36 – continued from previous page

<code>Series.cumsum(self[, axis, skipna])</code>	Return cumulative sum over a DataFrame or Series axis.
<code>Series.describe(self[, percentiles, ...])</code>	Generate descriptive statistics.
<code>Series.diff(self[, periods])</code>	First discrete difference of element.
<code>Series.factorize(self[, sort, na_sentinel])</code>	Encode the object as an enumerated type or categorical variable.
<code>Series.kurt(self[, axis, skipna, level, ...])</code>	Return unbiased kurtosis over requested axis.
<code>Series.mad(self[, axis, skipna, level])</code>	Return the mean absolute deviation of the values for the requested axis.
<code>Series.max(self[, axis, skipna, level, ...])</code>	Return the maximum of the values for the requested axis.
<code>Series.mean(self[, axis, skipna, level, ...])</code>	Return the mean of the values for the requested axis.
<code>Series.median(self[, axis, skipna, level, ...])</code>	Return the median of the values for the requested axis.
<code>Series.min(self[, axis, skipna, level, ...])</code>	Return the minimum of the values for the requested axis.
<code>Series.mode(self[, dropna])</code>	Return the mode(s) of the dataset.
<code>Series.nlargest(self[, n, keep])</code>	Return the largest n elements.
<code>Series.nsmallest(self[, n, keep])</code>	Return the smallest n elements.
<code>Series.pct_change(self[, periods, ...])</code>	Percentage change between the current and a prior element.
<code>Series.prod(self[, axis, skipna, level, ...])</code>	Return the product of the values for the requested axis.
<code>Series.quantile(self[, q, interpolation])</code>	Return value at the given quantile.
<code>Series.rank(self[, axis])</code>	Compute numerical data ranks (1 through n) along axis.
<code>Series.sem(self[, axis, skipna, level, ...])</code>	Return unbiased standard error of the mean over requested axis.
<code>Series.skew(self[, axis, skipna, level, ...])</code>	Return unbiased skew over requested axis.
<code>Series.std(self[, axis, skipna, level, ...])</code>	Return sample standard deviation over requested axis.
<code>Series.sum(self[, axis, skipna, level, ...])</code>	Return the sum of the values for the requested axis.
<code>Series.var(self[, axis, skipna, level, ...])</code>	Return unbiased variance over requested axis.
<code>Series.kurtosis(self[, axis, skipna, level, ...])</code>	Return unbiased kurtosis over requested axis.
<code>Series.unique(self)</code>	Return unique values of Series object.
<code>Series.nunique(self[, dropna])</code>	Return number of unique elements in the object.
<code>Series.is_unique</code>	Return boolean if values in the object are unique.
<code>Series.is_monotonic</code>	Return boolean if values in the object are monotonic_increasing.
<code>Series.is_monotonic_increasing</code>	Return boolean if values in the object are monotonic_increasing.
<code>Series.is_monotonic_decreasing</code>	Return boolean if values in the object are monotonic_decreasing.
<code>Series.value_counts(self[, normalize, sort, ...])</code>	Return a Series containing counts of unique values.

4.3.8 Reindexing / selection / label manipulation

<code>Series.align(self, other[, join, axis, ...])</code>	Align two objects on their axes with the specified join method.
<code>Series.drop(self[, labels, axis, index, ...])</code>	Return Series with specified index labels removed.
<code>Series.droplevel(self[, level[, axis]])</code>	Return DataFrame with requested index / column level(s) removed.
<code>Series.drop_duplicates(self[, keep, inplace])</code>	Return Series with duplicate values removed.
<code>Series.duplicated(self[, keep])</code>	Indicate duplicate Series values.

Continued on next page

Table 37 – continued from previous page

<code>Series.equals(self, other)</code>	Test whether two objects contain the same elements.
<code>Series.first(self, offset)</code>	Method to subset initial periods of time series data based on a date offset.
<code>Series.head(self, n)</code>	Return the first <i>n</i> rows.
<code>Series.idxmax(self[, axis, skipna])</code>	Return the row label of the maximum value.
<code>Series.idxmin(self[, axis, skipna])</code>	Return the row label of the minimum value.
<code>Series.isin(self, values)</code>	Check whether <i>values</i> are contained in Series.
<code>Series.last(self, offset)</code>	Method to subset final periods of time series data based on a date offset.
<code>Series.reindex(self[, index])</code>	Conform Series to new index with optional filling logic.
